of bottom-heat; on the contrary, his pot Vines, as soon as fairly rooted, are grown on the cool floor of the houses. They are arranged in lines and arches, and have a charming effect. Early Vines for forcing had completed their growth when I saw them last September, and were resting behind north walls. A large trade is done in these for early work, the first crop paying for the plants many times over. But the mode of furnishing the houses is the most striking example of the saving of time in the art of production. The Vines were only planted in 1870, and in 1872 the Vineries were full of Grapes. This was accomplished by beginning with Vines raised from eyes of extraordinary strength, and by planting two sets of plants in each house, one inside to cover the tops, and the other at the bottom of the rafter, with a choice of two borders, outside and in, for the roots. The lower plants are the permanent Vines, and the higher ones the supernumeraries for fruiting at once, and for being cut out when the others are strong enough to occupy the whole area. Between the two sets the Vineries are almost fully furnished, and carried about 10,000 lbs. of fine fruit last year. Nevertheless, wood, leaf, and buds alike looked as if they liked it, and were ready to multiply the yield in any ratio this season.

The chief vineyard, as already stated, consists of a block of three houses each 200 feet long, 24 feet wide, and about 15 feet high, covering a space with their intermediate borders about 130 feet wide. This is occupied at one end with a fourth vinery running at right angles with the others. This transverse house is of the same width and height as the others. What are these Grapes of a bright golden hue which I see yonder—enormous both as regards size of bunch and berry? "That's the Duke," said Mr. Thomson, and he gave me a bunch to carry home with me. All went well with my much prized present till I reached Peebles. At that station there was a rush of passengers and a sudden change of position. In an instant there was an abundant flow of juice. Had the waste steam-pipe been turned on under my seat? Not at all. I had only sat upon the Duke! This fine Grape is not fleshy. Oh no! I wished just then it had been; and it has no Muscat flavour, both high recommendations to my mind. It has, however, a sparkling refreshing flavour of its own, more closely related to an exquisite Sweetwater than a Muscat. In short, in appearance and also in flavour it is more like the Golden Champion in a perfect state than any other Grape with which I can compare it. But here is the difference. We seldom see the Golden Champion perfect. It spots as a rule, at least it has done so hitherto. What the Hamburg is among black Grapes the Duke of Buccleuch is likely to become among white ones. It is no rival to the Muscat, but it will probably supersede other white kinds of Grapes. Planted at the same time as Hamburgs it ripens fully a month or six weeks before them, and in this respect it resembles the fine old Buckland Sweetwater. The bunches average from 2½ to 3½ lbs. in weight, and the berries are the largest of any Grape with which I am acquainted. Mr. Thomson has furnished two of his vineries with it, and it commands nearly double the price of other sorts in the market.

The Duke of Buccleuch also keeps well. Grapes of it ripe in July continued sound till October, and this is long enough for any white Grape to hang, unless, perhaps, it be the Muscat or white Lady Downes. Time and space would fail to notice all the other houses, furnished in their proper season, from wall-plate to sharp roof apex, with a steep slope of Grapes almost rubbing each other. The vineries are clear of other inmates, affording full view from end to end; and the sight is worth going miles to see. Besides the Duke, there are Hamburgs, Lady Downes, Alicantes, Muscats, Gros Colman, and others. All the vineries are exactly of the same character—wide, high, and roomy, as well as long. With the exception of the Duke, they are all intended for late crops. Their form is admirable for keeping the fruit, as was found this unprecedentedly wet winter. With the air swept in over the hot-water pipes at the bottom, and rushing out at the ventilators on the crown of the roof, no drop of water or condensed vapour can rest on leaf or berry. The position of the ventilators at the summit of the narrow ridge also prevents the possibility of scorching. In a word, the vineries are admirably suited for the purposes to which they are put. The Vines, as has been stated,

were raised from eyes, which are either rooted on square pieces of turf or in pots, and planted out in a prepared bed, until established. When about 2 feet high, each is cut out with a block of roots about 6 inches square, and transferred to the fruiting pots, or planted out, as the case may be. The borders are simply raised a little above the natural level, which is nearly that of the water, and are formed with the natural soil, enriched with a few inch bones. The houses, though good, have nothing in themselves to command success. What we see at the Tweedside vineyard is the result of skilful culture.

The pot Vines, from their vigour and numbers, are as marvellous in their way as those planted out. Thousands of them are raised and prepared for fruiting annually. Many of these Vines are purchased to fruit but once. The strongest of these will carry an average of from six to eight bunches, and if ripened in April or May they are very valuable.

About 500 feet of quarter span-roofed houses, 16 feet wide, and 200 feet of pits, 7 feet wide, are devoted to the fruiting and growing of Pine plants for sale. In September last the Pine houses were being enlarged. Mr. Thomson intends to fruit from 900 to 1,000 annually when he gets into full swing, ripening most of them in winter and early spring, when they bring the highest prices in the markets. In the autumn the imported fruit, though worthless compared with English-grown Pines, nevertheless bring down the prices, and render Pine growing unprofitable. They are Pines, and that sufficeth for many. Mr. Thomson is, therefore, devoting his attention chiefly to that finest of all winter Pines, the smooth-leaved Cayenne. He also grows quantities of Queens, Charlotte Rothschild, Black Prince, Montserrat, and Prince Albert, the latter a new Pine, of which Mr. Thomson and his brother, at Drumlanrig, think very highly. Nothing could exceed the health and cleanliness of the stock of plants. They are without spot, and have that look of well-doing, so difficult to put in words, and so easily seen, that satisfies growers at a glance. No one could desire to handle finer Pine plants.

The sight of such fine Vines, and Grapes, and Pines is something never to be forgotten, but more pleasant still is the memory of the walk by moonlight to Ashiestiel, the simple home-like hospitality and the linking of the gentle art of horticulture to the nobler guild of literature throughout the evening's friendly fellowship.

D. T. FISH.

### FRUIT-TREE TRELLISES.

THAT iron is a better material than wood for training fruit-trees there cannot be a doubt. Its advantages are, that it is more durable than wood, and if galvanized requires no paint; it does not harbour insects, and its bulk can be reduced to a minimum. Therefore let those who have it already, or who can afford to purchase it at its present cost, be thankful—in the former case, that they have it; in the latter, that they can have it if they like. But for those to whom the expense of iron is an objection, I recommend a plan that I have followed for many years, and by which any man who has a carpenter's shop on his premises, and a pair of hands to work in it, can complete in wet weather all that is wanted for his trees that are to be trained as espaliers. The mode of proceeding is as follows: Procure from the nearest timber yard a few hundred feet of the lath used for fixing blue slates,  $1\frac{1}{2}$  inch by  $\frac{3}{4}$  inch. Plane their four sides, and then make two rods out of each by a saw-cut down the middle. Each lath will give you two rods 21 feet long, and about five-eighths of an inch square, and they can be finished by planing the fourth side of each rod. With these construct your trellises, using  $1\frac{1}{2}$  inch flat-headed nails where the rods cross each other. Do not notch them at the junctions, as that process not only weakens them, but takes up a needless amount of time and trouble. Even without paint they will last many years, if a little of that material is applied between the joints and on the heads and turned points of the nails. If the wood is well seasoned it can be painted at once, but if there is fear that it is not thoroughly dry it had better stand a year before it is painted. The quickest way to paint the trellises is to give each rod one or two coats of paint before they are nailed together, and a third coat afterwards; but previously touching with paint the heads and points of the nails, as directed before. These

trellises can be made in any form that may be preferred. My practice is to make them of various sizes to suit the ages and dimensions of the espaliers. And here will be noticed one advantage that wood has over iron. Trellises so constructed can be shifted with ease from one situation to another, and their dimensions adapted to early or late training. When a tree has outgrown one trellis, a larger one will take its place, and it will be at liberty to be used for a tree of earlier growth; whereas, the usual arrangement with iron is to stretch wires along the sides of the walk,

Espalier Trellis.

where the trees have been or are yet to be planted, to set up at once the entire structure, not half of which will be occupied for many years, perhaps not until the iron begins to show here and there through the coating of zinc that protects it. With wooden trellises each tree can have just that amount of support that it requires for one or two years, and your various forms come in usefully at every addition you make to your stock of trees. Another advantage that may be stated in favour of these wooden trellises is that they can at any time be taken to pieces, their length reduced, and their form and proportions altered; and it is therefore desirable in putting them together not to clench the nails thoroughly, but only to turn their points in such a manner that they can easily be broken off, and the nails drawn and removed. The cost of such trellises as are here recommended may be estimated by a description of one that is suitable to a tree whose branches run on either side rather more than half-way into the allotted space. Four 21-foot laths will each make two rods of the same length. From the ends of two of these rods cut off 3 feet. From the ends of two more cut off 6 feet, from the third pair cut off 7 feet 6 inches, and let the fourth pair remain the full length. These short lengths will make the uprights, and the longer must be nailed to them lengthwise, placing the shortest at the top and the longest next the ground, and about 9 inches from each to each. The 3 feet lengths should be nailed near the ends of the third and fourth rods, the 6 feet lengths at about  $2\frac{1}{2}$  feet from the latter towards the stem of the tree, and the 7 feet 6 inches  $2\frac{1}{2}$  feet nearer. The tops of the six uprights should rise about an inch above the highest rod, and it will be found that the two longest uprights will extend a little over

Mode of forming Espalier Trellis.

2 feet beyond the lowest rod. These two are intended to go into the ground about a foot, to steady the trellis, and keep it in its place, its real support depending on two strong stakes driven into the ground near the ends of the top rod, the trellis standing sandwich fashion between them and the tree, and the trellis itself being secured to the stakes with fastenings of copper wire. Now, if we reckon the expense of such a structure by the value of the materials used, we shall find that the cost cannot much exceed 1s. 6d. The lath can be got for 2s. or 2s. 3d. the 100 feet, the stakes at 1s.

the score, and nails, paint, and copper wire for about 3d. When the trees get beyond the constraint of such a trellis as this, they are just as well without any more support than a few good stakes here and there, and a trellis only at each end of the tree, the pair costing no more than the one just described. The two uprights that go into the ground will require renewal every five or six years; how long the rest will last must, I suppose, depend in some measure on the quality of the wood—mine show no signs of decay at present. When the top branches of an espalier have grown to their full extent, they require no longitudinal support anywhere but at their extremities. Even wire ceases to be of any use; and as for wooden rods, they are only in the way of the blossoms and fruit. As regards the height of espaliers above the ground, that must depend in some degree upon the locality and the object of the grower. If he wishes his trees not to obstruct the rays of the sun from reaching his crops of vegetables, the old-fashioned 5 feet is certainly the best; and my experience does not agree with that of one of your correspondents, that Pears will not do well on such trees. For southern aspects, with a walk along the north side, 6 feet is a good height; but for trees whose branches do not run east and west, 5 feet or a little more answers very well, and does not cast an inconveniently deep shadow. In the early

Parham's Wall Coping.

growth of espaliers great care should be taken to keep the lower branch well in advance of the one above it—a foot would not be too much. Especially look after the top and bottom branches, keeping the latter a good 14 inches from the level of the ground, and being very careful to protect their leading shoots, and allowing a few laterals to remain on longer than on other parts of the tree, with a view to encourage the sap to flow into that part of the tree which, under ordinary circumstances, it would be likely to desert. But with the upper tier the reverse of this practice must be adhered to, to prevent the formation of a "tête de saule," by which trees trained horizontally are so often disfigured. A modification of that beautiful form recommended by Du Breuil, called the palmette, will be found to facilitate these objects, and to keep every part of the tree in a bearing state; but the two leaders of a tree that has filled its allotted space, or is advancing towards that condition, will require constant and careful thinning, and should be the first to have their shoots shortened at the summer pruning.

In putting the trellises together, it might be found of advantage to increase the space between the rods downwards, by giving them an interval of 8½ inches at top and ending with 10 inches. By this arrangement the thicker branches

would be more likely to receive their proper share of air and sun. Equal parts, or nearly so, of red-lead, white-lead, and black paint will be found a good mixture for covering the trellises, varying the proportions according to taste. B. S.

#### PARHAM'S WALL COPINGS.

JUST now, as the fruit trees on many walls are suffering from the want of a little protection from frost and sleet, we may appropriately call attention to one of the best and simplest contrivances for guarding against these evils—Parham's glass copings, which we first noticed at the Birmingham Show. This coping is made in 6 feet lengths (except the end lengths, which are 3 feet), and is generally made 2 feet deep, or for high walls 3 feet deep. It is fixed to the wall by screws into wooden plugs or wall plates under the stone coping, and is steadied by iron stays reaching from the front bars to the wall, at every junction of the lengths. The framework of the coping consists of wrought iron channelled rafters 2 feet apart, strongly riveted into iron front and back bars, the front bars cranked for joining at ends of each length. On these rafters the glass rests in squares about 1 foot deep by 2 feet wide, two squares to each panel, and is kept in place by light iron cover plates, secured by two screw pins with brass nuts to each rafter. To remove the glass it is only necessary to unscrew the brass nuts, and if it is desired to take down the iron framing it can be readily done by drawing the screw attaching it to the wall. We have heard a good account of this simple coping wherever it has been employed. Mr. Parham informs us that his correspondents say that last year they had little or no wall fruit, except where protected by these copings, which fully bears out what was said of copings in the "Parks and Gardens of Paris." For high walls a wide coping, say three feet, is better than the narrower one at two feet. It is easy to suspend canvas or netting from the outer edge of the coping to the ground and Mr. Parham provides for this when desired; but given a good glass coping 2 or 3 feet deep, and further protection we believe to be needless.

**Easter Beurre Pears in America.**—In the last issue of our excellent contemporary, the *Albany Cultivator*, we find the following:—The editor of the London *GARDEN* says:—"We have just tasted Easter Beurre Pears that have come all the way from California, and they are decidedly superior to either English or French fruit of the same kind, the flavour being very fine, and the flesh of a more even and tender texture than that of European grown Pears." We have received many specimens of the Easter Beurre from California, in perfect condition, which ripened in first-rate order. They were very large, about 4½ or 5 inches in diameter, and weighed each from a pound and a quarter to a pound and a half. The flavour was not equal to that of the specimens raised in this State. Are we, therefore, to infer that our Easter Beurre's are better than those of English or French growth?

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**L'Homme Lefort's Grafting Wax.**—I have received a tin of this wax with a rather loosely fitting lid; consequently the wax is stiffer than it ought to be, and of course not so easy to work. Can you tell me of anything that will soften it, and make it usable?—N. H. POWSALL. [Heat is the only thing likely to soften it.]

**Pears for Espaliers.**—Will you or some of your readers kindly tell me what are the best Pears to plant against espaliers?—ALPHA. [Take Louise Bonne of Jersey, Marie Louise, Winter Nelis, Doyenne du Comice, Thompson's, Easter Beurre, Beurre d'Amanlis, Seckle, Beurre Sterkinian, Passe Colmar, Knight's Monarch, and Josephine de Malines.]

**The Sweet-and-Sour Apple.**—There is a well-known Apple in America, which in some parts is less sour than in others, and which is known as the Sweet-and-Sour. Various theories have been put forward to account for this phenomenon. The matter is now, however, set at rest by a New York evening paper, which says:—"It has been supposed sap-tubes running side by side from the roots of the tree, pour their secretions on the two sides of the fruit, which present a sort of Silesiac connection, although they are really two distinct Apples—a sweet and a sour—in juxtaposition." Who shall venture to speak lightly of newspaper science after this?

**The Mexico Apple.**—American papers speak in high terms of this new Apple. The *Apprentice* says that it "is the best Apple of its season. The tree is hardly a good grower, and on good soil, very productive. The fruit is of medium size, round, regular; surface bright crimson red, with darker stripes; dots, numerous, yellow-green. The basin is shallow, regular; eye medium, closed. Cavity acute, regular; stem long or medium, slender. Core large, open, meeting the eye. The flesh white, tender, fine grained, and juicy. Flavour, subacid. Quality, best; season, August and September. A superb dessert Apple; worthy of a place in any collection, however small." Such an opinion from such an authority should lead to its trial in this country.

## THE KITCHEN GARDEN.

### RENOVATING A KITCHEN GARDEN.

THAT soils in kitchen gardens get worn out is a fact proved by experience; and, although your correspondent "J. T." may have taken the best mode of renovating them in his particular case, let him bear in mind that his plan is not suitable everywhere, unless the operator is thoroughly satisfied as to the drainage. The garden in which I am employed was renovated about twenty years ago by means of two feet of fresh soil being applied to it—an act of generosity on the part of the then owner (who did it to give bread to a number of villagers that would otherwise have starved)—and the result is that the present proprietor has nothing but barren trees and a water-logged garden. Having ascertained that, after being here a short time I recommended the removal of the old trees after the manner of your correspondent; but there being no family, I was told distinctly that no expense was to be incurred on account of the garden farther than what was necessary. Not being content that all the time expended in pruning, nailing, &c., should be spent in vain, I resolved on lifting the roots; but judge my surprise when, going out the morning after commencing operations, I found the trench nearly full of water, which took ten days to subside. Defeated for the time, but not disheartened, I have continued to effect a little improvement ever since. I have trenched the ground two, and in some parts three spits deep, the manure in all cases being put in the bottom. I do what I call my deep trenching in October, if possible. In regard to the subsoil, it must come to the surface. I have turned up some that would almost chill your correspondent to look at. Directly the new year is past, time and weather permitting, I put as much short manure on it as can be spared, and all the gas lime collected for twelve months I dig into it. It is again pointed over before it is cropped. The first crop, in all cases, has been Potatoes, of which I have always had an excellent crop, and very little disease. The half-rotted manure put in the bottom of the trench I never allow to lose any of its properties by over-fermentation, and hence its adaptation to the growth of vegetables, by what I call the "expedition treatment" (see p. 531, Vol. II.), which follows the year after, and every year there is as much as possible done on the same principle, in all cases using stable manure. As for what is called plain digging, *i. e.*, one spit, it would be of no use here, if it is possible at all to give it two. Our vegetables are as good as any in the district; my Peas (Veitch's Perfection) were only three days finished before "J. T.'s." Your correspondent says, "in many cases fresh soil would be preferable to dung itself, which may have been applied year after year to the same ground for several generations;" but it is not everywhere soil can be got for such a purpose. Gentlemen are in general too fond of their farms and parks to allow gardeners that privilege.

CALEDONIUS.

### AMERICAN POTATOES IN ENGLAND.

TAKING these Potatoes as a whole, they are neither better nor worse than many of our own kind, as regards the matter of cropping, and certainly inferior to our best sorts with respect to eating quality. As to their power to resist disease, an average of results as to immunity or otherwise, shows without doubt that a majority of the American kinds have suffered less than a majority of English sorts have; but, as our kinds are higher bred and of improved quality, the reason that they suffer most is at once manifest. Still, it must be acknowledged that in thus possessing kinds (although of foreign introduction) that are of such comparatively healthy stocks, our gain has been considerable; and when the crops of certain favourite sorts run short, we are glad to have others to fall back upon. The most prominent kinds have been and still are a particular few, the most popular of which perhaps is Red-skin Flour-ball, a sort which was first sent out under the name of American Red. It has a large tuber, coarse in appearance, with deep eyes, and always produces a heavy crop. It should always be grown on light soil, not recently enriched with manure, and the produce should be kept over Christmas before eating, after which it will be at its best. To cottagers and persons who are not too fastidious, Flour-ball in bulk is during the winter a most acceptable store. The Early Rose, although a great cropper, proved to be of good cooking quality in such a small number of cases, and is so generally coarse and full of eyes, that it has greatly declined in popular estimation. Gleason's Late, a large flattish long kind, having a white skin, coloured with wide bands of bright red, and more recently introduced to the public under the name of Hundred-fold Fluke, is a late variety, producing a heavy crop of large tubers, having flesh yellowish-white in colour, and moderately mealy when cooked. It is a capital keeper. On the whole, I consider this kind preferable to Flour-ball. Perhaps the best two of all the American

sorts are Climax and Prolific. The first is a large, coarse, deep-eyed tuber, never handsome, but having very white flesh, and comes more closely to our Regent than any of the rest; the skin is roughly netted, and when cooked the flesh is mealy, and, if the tubers are not too large, cannot easily be distinguished from the Scotch Regents. It is a large cropper, and is not unlikely to become a favourite with some of our market growers. In the matter of crop and appearance my favourite is Prolific, a sort that, if grown in moderate soil, produces a large quantity of clean even tubers, somewhat pebble-shaped, having shallow eyes, and presenting altogether qualities that make it the most acceptable of the lot for exhibition. It keeps well, and even improves by keeping. The skin is of a brownish white, and the flesh is white. Late in the winter it cooks mealy and good. I heartily commend the cultivation of this kind to all who have not yet tried it. The Late Rose has been strongly commended as a good keeper, and of improved quality, but when it grows large it is full of deep eyes. It bears a close resemblance to the Early Rose, but the skin is rougher. I have mentioned but six sorts; there are, however, as many more kinds of American raising, but I believe I have pointed out the best. The family likeness that runs through them all is apparent, and American raisers would do well to import some of our choicest sorts in order to improve their own strains. If we hybridise in the same direction, Potato growers on both sides of the Atlantic will be mutual gainers.

A. D.

**A French Vegetable Market.**—The stalls or sittings are in regular lines; and the pavement is so broad that there are two or three avenues along its width; the purchasers passing easily up and down, chaffering, joking, and packing their baskets. Here and there we come upon a true lady of the Halle, of powerful arm and shoulder, potent voice, and fresh, hard, staving face. The vegetable women outside are, to her, the vulgarians of the market. A stately lady sits, just within the market gates, deigning to sell piles of Artichokes at one and two sous each. An old gentleman endeavours to bargain with her; but she tells him loftily they are to be taken or left at the marked prices; and he ends by putting three into the tails of a snuff-brown coat that had been seen many seasons. He had a keen French face, I thought, like Voltaire's in the foyer of the Comédie Française. The Endive is superb, in yellow tufts, of the form and proportions of Louis Philippe's pyramidal wig. The Barbe-de-capucin, in long golden tresses, was compared, by the gallant Baker, to naiads' tresses; then there were Onions in bunches at one sou each; and then artistically bound groups of vegetables—Carrots, Turnips, Onions, Leeks, and herbs—for the bouquet garni, as the cook calls it. These bouquets of vegetables—which vary in price from two to five sous, according to their size—are the vegetable ingredients of the pot-au-feu. The bouquet garni is a work for the cook's own hand to perform. She takes Thyme, Chervil, Parsley, and an Onion for centre piece, in which she sticks half a dozen Cloves, and—just a suspicion of Garlic. This she casts into the pot-au-feu. "Bless me—winter; and here are delicious spring Radishes at a penny a bundle!" Mr. Baker suddenly exclaimed. Then rapping his umbrella upon the pavement, he turned sharply upon me, and added, "Will you be good enough, Fin-Bec, to inform me why I cannot have these at my own house this time of the year?"—*All the Year Round.*

**Method of Preserving Cabbages in Winter.**—The following method of preserving Cabbages in winter is much employed in France:—The Cabbages are stripped of all their green leaves, and the rounded heart or head is hung up to dry for some days in an airy place. They are then very finely sliced with a sharp knife, and placed in thin layers in sieves, which are hung up in an airy place. The sliced Cabbage is also stirred every day in order to facilitate the absorption of its moisture by the air. After this the sieves are exposed for some time to the heat of a cool oven, until the contents are thoroughly dried. Cabbage treated in this way does not change its colour, and very much resembles vermicelli in appearance. It loses about one-third of its bulk in the course of the process. When quite dried it is kept in bags hung up in a very dry and airy place. It should be examined from time to time, and if there is any appearance of moisture, it should be again placed in the oven. If this is not done, it soon rots. In cooking it, it is first soaked for some time in water, and then boiled like fresh Cabbage, from which it is very difficult to distinguish it in taste when served up.

**Potatoes.**—Will any readers of THE GARDEN favour me by saying if they know a Potato named "Snow Flake," and if so where it can be obtained?—R. GILBERT.

**Cutbush's Magnum-Bonum Pea.**—When fully known this Pea will be grown as extensively as that invaluable variety, Veitch's Perfection. The flavour, habit, and productiveness are all that can possibly be desired. The variety is, therefore, certainly worthy of a place in every garden.—THOMAS RABONE, *Alton Towers.*

THE INDOOR GARDEN.

CYPRIPEDIUM VEITCHII.

Of the many forms which the Bearded Lady's Slipper (*C. barbatum*) has taken, this is one of the best; indeed, when well grown it may be considered to be one of the noblest *Cypripedes* in cultivation. Its nearest rival in the group to which it belongs is the scarce, but somewhat less beautiful *C. Dayii*, a variety which differs from *C. Veitchii* in its broad ribbon-like petals being striped, and not spotted. All the varieties of *C. barbatum* may be grown in an ordinary plant stove, where they may be had in flower for upwards of three months during spring and summer. They grow well in a compost consisting of fibrous peat, rough lumps of loam and dried cow-dung, together with an admixture of coarse sand and broken crocks, and the surface of the compost should be covered with a layer of fresh Moss, which hides the soil, and gives the pots a neat appearance. The pots should be thoroughly well drained, and an abundant supply of water is essential to the plants when they are making their growth. *Cypripediums* should never be allowed to become dry, as they have no pseudo-bulbs to fall back upon, and if they get into a parched and shrivelled condition they are extremely liable to the attacks of thrip and red-spider. Repeated sprinklings with a fine syringe goes a great way towards keeping them in a clean and healthy condition, and when in a fresh vigorous state few Orchids are more interesting than the one we now figure, and its congener *C. Dayii*.

F. W. B.

COCCOCYPSELUM DISCOLOR.

Nothing in its way could possibly be more charming than this pretty little plant has been during the past winter, laden, as it has been, with beautiful blue berries, which have remained plump and brilliant during the dullest period of the year. My plants are grown in wire baskets, lined with sphagnum and filled with a compost of fibrous loam and peat, with the addition of a little leaf-mould and silver sand. The baskets are suspended from the rafters in a tropical aquarium, but I have no doubt that a moist stove would suit this plant quite as well. It is associated with other basket plants, such as *Torenia asiatica*, various kinds of *Eschynanthus*, *Asystaccas*, variegated *Panicum*, and Ferns of different kinds, but I cannot say that I approve of the mixture. The *Coccocypselum* I apprehend would look best alone, or with the addition only of a few seedling *Adiantums*, or Club Mosses of the *Martensii* section, inserted between the meshes of the wires. Thus managed, whether laden with its lapis-lazuli coloured bead-like berries or not, it would form a pleasing object. Young plants of it may be raised from seeds, separated from the soft portion of the berry, and sown in a close stove temperature now. Raising plants of this from seed is, however, seldom resorted to, for they may be readily obtained by

layering the shoots on the surface of the baskets; every joint thus layered will emit roots; two points are, therefore, thus secured, viz., the equal spread of the shoots for the time being, and the rooting of the layers for division and transplanting into separate baskets at the general potting season, which is generally about this time of year. The points of the young shoots may also be taken off, and inserted under a hand-light or bell-glass in the stove, well shading them for a time from the sun, when they will soon strike root; afterwards pot them off singly. If practicable, give them the advantage of some bottom heat, and excellent plants will be the result. In early spring, place two or three of them in a basket, treat them like old plants, and in winter a crop of bright berries will be the result.—M. M., *Liverness*.

SAXIFRAGES, ETC., AS INDOOR PLANTS.

At page 210 of the present volume of THE GARDEN, I notice that Mr. Williams, with good reason, has directed attention to the value of various species of the genera *Saxifraga*, *Sedum*, and *Sempervivum*, as indoor decorative plants, and throws out several capital suggestions as to the various ways in which they may be grown for that purpose. But, for what reason I know not, he gives *Saxifraga longifolia* as the "most lovely species known." It may be the finest as regards its beautifully formed en-erusted rosettes, of which I have seen several splendid specimens nearly a foot in diameter; but for freedom and beauty of bloom, there are other species in its own section that quite equal and, I think, surpass it in the handsome pyramidal spikes which they produce, to wit, the true *S. pyramidalis*, which I have seen, both in pots and planted out, throw up a spike nearly 2 feet high, and literally covered with panicles of large, white, and prettily spotted flowers from the base to the summit. Then, again, there are several members of the large-leaved section, which, as regards beauty of bloom, I think also superior to *S. longifolia*. Of these I would mention *purpurascens*, which produces dense corymbs

*Cypripedium Veitchii*.

of lovely rosy-purple flowers, and *S. ligulata*, a large-leaved species from Nepal, which also produces showy flowers of a rosy colour. Passing on to his selection of twenty-four *Saxifrages* suitable for planting in a one-light frame, Mr. Williams omits such choice gems as *Rocheiana*, *cesia*, *aretioides*, and *diapensioides*, all of which are eminently suited for this purpose, and moreover he omits his lovely *S. longifolia*, of which fine specimens have been grown in such a position. A first class selection of twenty-four *Saxifrages* for growing in the way just indicated I think will be found to be the following:—*S. longifolia*, *pyramidalis*, *pectinata*, *cesia*, *aretioides*, *diapensioides*, *Rocheiana*, *Aizoon*, and *incrustata*, belonging to the en-erusted section, all distinct and good kinds; *S. palmata*, *atropurpurea*, *muscoides*, *caespitosa*, any of the varieties of *hypnoides*, and *gibraltarica* amongst the mossy section; and the following nine not included in either of the above sections, and which are quite distinct in character, viz., *juniperina*, *Guthriana*, *oppositifolia*, *retusa*, *aizooides*, *aspera*, *Bucklandii*, *ceratophylla*, and *dalurica*, the last of which is included in Mr. Williams' list, as is

also capillaris, which I have always found to be the same as dahurica. The selection of twelve Sedums made by Mr. Williams is not the best, and I would suggest the following as a more suitable selection for frame culture, viz., *Sedum anglicum*, album, brevifolium, dasphyllum, farinosum, spurium, grandifolium, rupestre, Sieboldii, Ewersii, Sempervivum, and glaucum. His suggestion as to these plants being grown in glass cases is a good one, and one that if carried out would doubtless yield enjoyment to many, but for this purpose none but the very choicest should be selected. I would particularly recommend such Saxifrages as longifolia, Rocheliana, caesia, arctioides, pectinata, Guthriana, juniperina, muscoïdes, palmata, and Bucklandii as likely to give the greatest satisfaction grown in that way, and as having the greatest diversity of form. All the Sedums given in my list will do for the purpose, but I would omit Sieboldii and Ewersii, as they are herbaceous species, and are only attractive in the summer months, whereas the remaining kinds are always interesting.

Of the genus *Sempervivum*, of which Mr. Williams has not made a selection of species, I would suggest the following as being a good list of twelve kinds for ordinary uses, viz.:—*S. arachnoïdeum*, calcareum, flagelliforme, glaucum, Pittoni, Mettenianum, triste, montanum, Wulfenii, piliferum, spinosum, and chrysanthum; the two last being often called Umbilicus. The above enumeration will be found a very suitable one for frame culture; but in reducing the list to six species as most worthy of being grown in pots or glass cases, as suggested by your correspondent, I would particularly recommend *S. spinosum*, *Wulfenii*, *arachnoïdeum*, *montanum*, *calcareum*, and *Mettenianum*, as being quite distinct in form.

In addition to the modes of culture suggested by Mr. Williams, I would add another way in which such plants may be grown successfully, and one that is within the reach of all classes. I allude to their culture in pots on the window-sill, a way in which I have grown many of them successfully. Indeed, some of the plants belonging to these families are among the most useful subjects that can be had for window decoration, for they are attractive at all seasons, either in flower or out of flower. Last summer I saw in Garvatt Lane, Wandsworth, a cottage window-sill containing about six pots of *Sedum album* in bloom, and so profuse was the blossom that the window-sill appeared to be a complete mass of pinkish-white inflorescence, that fell over and completely hid the fronts of the pots. This species does well in pots, and many others will likewise succeed well in similar situations. The soil which I use for such plants is a mixture of about two-thirds good yellow loam and the remainder about equal portions of river sand and leaf-mould. The chief thing to guard against is their becoming too dry; I always give my plants a good supply of water during the growing season from March till the beginning of October; but during the other months the rainfall is usually sufficient. A GROWER OF HARDY SUCCULENTS.

Battersen, S.W.

## THE ARBORETUM.

### PLANTING FOR ORNAMENTAL COVER.

A CORRESPONDENT asks for some information about planting the ground with low shrubs, to save the expense of mowing, to look ornamental, and at the same time to form a good covert for pheasants. There are various ways of doing this—the simple, the ornamental, and the elaborate—each of course requiring its proportion of expense. At Holkham many of the plantations are carpeted with St. John's Wort, which grows to the height of a foot, and forms, intermixed with Fern and Brambles, a capital summer covert for birds. At Claremont scores of acres of the shrubbery walks are covered almost exclusively with common Laurel, which is pruned down to a certain height, say from 18 inches to 3 feet, and forms an admirable covert, through which beaters or sportsmen may pass with comfort. When interspersed with dwarf Rhododendrons and other American plants, such a covert may be made exceedingly ornamental. The Pinetum at Basing Park, when planted more than thirty years ago, was intersected with various gravel walks, and nearly the whole of the ground was planted with *Berberis Aquifolium*, which the keeper pronounced a capital covert, inasmuch as the berries afforded food and the bushes themselves shelter. These may be considered the simple methods of forming game covert; and there are scores of plants besides those I have mentioned which may be used for the same purpose, the cheapest of which undoubtedly is evergreen Privet. But in a Pinetum of choice trees something more than mere game protection may be desired, and then we should throw in groups of dwarf evergreen shrubs, so arranged as to produce a pleasing effect. Plants suitable for this purpose are plentiful, but the following are a few of the most popular:—

<i>Aucuba japonica</i>	<i>Juniperus prostrata</i>
Box	„ <i>tamariscifolia</i>
<i>Berberis dulcis</i>	„ <i>sabina</i>
„ <i>empetrifolia</i>	„ „ <i>variegata</i>
„ <i>Darwinii</i>	<i>Laurustinus</i>
„ <i>Aquifolium</i>	Laurel
<i>Cotoneaster microphylla</i>	<i>Ligustrum ovalifolium</i>
„ <i>acuminata</i>	„ <i>japonicum</i>
„ <i>Simmondsii</i>	<i>Tamarix gallica</i>
Holly, green and variegated	Gorse, double and common
<i>Hypericum calycinum</i>	Yew
Ivy of sorts	

Of what are called American plants I may name *Andromeda*, *Erica*, *Gaultheria Shallon*, *Kalmia*, *Ledum*, *Pernettya*, *Vaccinium*, and *Rhododendrons*. There is a wide field of evergreen shrubs, to which might be added a number of berry-bearing plants, foremost among which I would name, for its delicious odour, the Sweetbriar, and lots of climbing Roses, and above all the Blackberries. Then there is the Snowberry, *Symphoricarpus racemosus*, grateful food for pheasants I am told, and for some other things, though not a covert plant at least not for winter, I believe. One of the most useful plants that can be planted is the Jerusalem Artichoke. Pheasants are specially fond of this, but of these plants, or rather I should say shrubs, the arrangement must depend upon the taste of the planter. For example, I would not plant a light-foliage plant under a Deodar, neither would I plant a dark one under the Cedar of Lebanon or *Cedrus atlantica*; but I would so diversify the planting as to produce an agreeable whole with something of the picturesque about it. For example, the *Aucubas* and Golden Box and Hollies would give a fine patch of the palest green, or green and gold; while the *Berberis* would give dark green, or, in the case of the most beautiful of all of them, *B. Darwinii*, a very light tinge. Then of *Cotoneaster*, what can be so beautiful as *C. microphylla*, studded with its bright scarlet berries? I saw it one winter when the ground was snow-clad, backed by a dense mass of Yew, and I thought the picture was one of the finest I ever saw in winter. A slight mound raised up, or a few roots thrown down, and the Ivy, with the Clematis and Virginian Creeper, would clothe the whole with perpetual beauty. Then the prostrate Junipers—they form a complete carpet; and what so beautiful as to see Crocuses and various other bulbous plants peering through their branches early in spring.

W. P. A.

### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Grafting Pelargoniums.**—I have grafted five kinds on one stock, by way of experiment. The stock was Tom Thumb, the kinds Bijon, Mrs. Pollock, Christmas, variegated Ivy-leaf, and the common Ivy-leaf, all of which "took" well in a moderate bottom-heat in a Cucumber frame.—J. C.

**Foreign Evergreen Ferns.**—Kindly give me the names of such of these as you think would be suitable for a Wardian case.—W. W. [The following will doubtless answer your purpose, viz.:—*Adiantum cucullatum* and *hispidulum*, *Polystichum triangulare*, *Nephrodium molle*, *Asplenium bulbiferum* and *Fabianum*, *Davallia Nova-Zelandica* and *tenusifolia*, *Anemidictyon Phyllitidis*, *Blechnum occidentale*, *Cheilanthes alabamensis*, *Litobroekia vesperitonia*, *Nipholobus rupestris* and *pertusis*, *Platylochia rotundifolia*, *Polypodium Paradisea*, *Pteris cretica*, *Pteris scaberula* and *longifolia*, *Oncocoma japonica*, *Pleopeltis Billardieri*, *Lomaria lanceolata*, *Doodia binulata*, and *Lastrea glabella*.—G.]

**Cool Greenhouse Exhibition Plants.**—Would you kindly name a dozen greenhouse plants suitable for exhibition purposes, which may be got for a moderate price, and which would not be injured although the temperature might at times during the winter fall as low as 36°.—T. G. [You do not state the time at which you wish to have the plants in flower; if you require them from the middle of May to the middle of June, omit the last four of the following dozen, and if you want them from the middle of June to the middle of July, omit the first four, viz.:—*Adiantum fragrans*, *Punclea Hendersonii*, *Eperis Eclipse*, *Boronia punctata*, *Genetyllis tulipifera*, *Erica Cavendishii*, *Aphelaxis macrantha purpurea*, *Dracophyllum gracile*, *Phacocoma prolifera*, *Kalosanthes Phœnix*, *Aphelaxis macrantha rosea*, and *Statice profusa*.]

**Striking Yuccas.**—A very large *Yucca aloifolia* has been growing in the centre of a greenhouse here, the top of which it had reached, and as it was very much admired my employer wished me to shorten it a little if possible. I got a box made, measuring about eighteen inches across and twelve inches in depth; this box was made in halves, out of the bottoms of which I cut a small half circular bit, so as to allow the stem of the plant to pass through the box, which stood on three legs about four feet from the ground; I then got some good loam and leaf-mould, to which was added a portion of silver sand, and filled the box with the mixture. In April last I made an incision in the bark of the Yucca, and on examination the following autumn I found the box full of roots, which had issued from the incision, thus enabling me to lower my specimen four feet without detriment to the plant.—J. C., *Agle, Waterford*.

THE CUT-LEAVED MAPLE.

(ACER DISSECTUM.)

This forms a neat, deciduous, small, round-headed tree, from 10 to 15 feet high, with numerous, very slender, spreading, bright green shoots. It is a native of Japan and China, and was first introduced by Mr. Fortune in 1844. It is quite hardy, grows freely in any good garden soil, and is readily increased either by means of cuttings or layers. The leaves are distinctly seven or nine-parted to the footstalk, bright green, slightly villose when young, on long slender footstalks, and just before they fall in the autumn they assume a bright yellow hue. The lobes are parted to the footstalk, oblong, very acute, and either pinnatifid or deeply and sharply serrated. The flowers are small, red, and are produced in May in terminal stalked corymbs, containing from four to six flowers in each. The fruit or keys are small and smooth, with thick carpels and widely diverging oblong wings. This beautiful little Maple is well suited for planting singly on lawns, and deserves a place in every choice collection of shrubs, on account of its neat and elegant leaves. The length of a full-sized leaf is 5 inches including the footstalk, which is from 1 to 1½ inch long, and the breadth 4 inches. There is a very pretty variety of this Maple, with leaves of a bright purple, and which is known in the nurseries under the name of *Acer ornatum*.

Geo. Gordon, A.L.S.

THE MOVEMENT OF THE SAP.

YOUR correspondents, "A.M." and Mr. Chamney, do not seem to me to realise the multiplicity of actions at work in the ascent of the sap. As Dr. Bastian has ably argued in his "Beginnings of Life," that vital forces are but modifications of the ordinary physical motive powers—heat generated by friction, electricity by heat, magnetism by electricity—so the ascent of the sap is undoubtedly, to a large extent, but an instance of that great law of causation, that supply is relative to demand. Nature abhors a vacuum; water tends to find its own level; fluids of different density equalise their density by the process of "osmosis." The increased temperature of spring stimulates chemical action, and especially rarifies the air. This may cause osmosis either directly or indirectly by causing pressure. Pressure forces the fluids to move in the direction of least resistance. Capillary action probably starts the sap in its ascent; but because the leaves are not developed so as to cause osmotic action by transpiration, it does not follow that it cannot be caused internally by the sun's heat. The flow of the sap is greatest during the daytime. The transformation of starch into sugar, which occurs at a very moderate temperature, necessitates a supply of water and creates current, and the intermittent pressure caused by the wind very probably, as suggested by Mr. Herbert Spencer, gives motion to the sap in the direction of least resistance. It is a process of alternate exhaustion and re-filling, not quite a suction-pump arrangement. It has been suggested to me that the heart of an animal beats by successive chargings and dischargings of electric force, as in a Leyden jar, so that the blood traverses the body by a

force derived from a modified physical motive power. But the vegetable sap does not circulate as does the blood of animals. It ascends, is elaborated, transpiring water and acquiring carbon, by the decomposition of carbon-di-oxide, and descends; but is then abolished and never re-ascends.

LECTOR.

**Willows.**—Independently of the very considerable profit attending the growth of tree Willows, some of them are of great beauty. The white Willow (*Salix alba*), when not mutilated by pollarding, has both a beautiful and cheerful appearance in a landscape. The golden Willow (*S. aurea*) is also very handsome, and worthy of more notice than it has yet received, both as an ornamental and a timber tree. The Carter or red-twigged mountain Willow (*S. Carteriana*), with its dark-red branches and spiry head, is also eminently calculated to add beauty to our woodlands. The Royal Willow (*Salix regalis*), although not attaining to the size of some of the other tree Willows, is one of the most silvery trees we have, and although

it was introduced in the last century, it is hardly yet known to cultivators. *Salix Baxfordiana* and *Salix sanguinea*, two comparatively lately introduced varieties, are amongst the most beautiful deciduous trees we now possess. They are spiry-topped, and their manner of growth is similar to the well-known Bedford Willow, *Salix Russelliana*. The branches of *Salix Baxfordiana* are of a brilliant orange colour, tipped with red, and the branches of *Salix sanguinea* are of a clear vermilion colour, and in winter, when divested of foliage, with the sun shining upon them, are as bright as if varnished. They are both vigorous growers, and attain a large size, *Salix Baxfordiana* being the more vigorous grower of the two. They are perfectly hardy and will thrive in very exposed situations. It is also worthy of remark that the dense smoke of a town does not materially interfere with the healthy growth of Willows. To grow Willows in perfection they must be planted closely, say 3 feet apart each way, or 4, 8, 10

*Acer dissectum.*

to the acre would not be too close for the first eight or nine years, when they might be thinned out to half that number. The thinnings would find a ready sale for general purposes.—*W. Sealing.*

NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Weeping Ash.**—In the garden belonging to Emmanuel College, Cambridge, is a Weeping Ash some 75 feet in height, and in every respect a finely formed tree.—*J. J. C.*

**White Calycanthus.**—It is reported that a white-flowered variety of the *Calycanthus* has been discovered in middle Georgia. It blooms continuously until the first frosts.—*THE COLONEL.*

**Exotic Shrubs.**—The shrubs of which I spoke (see p. 234), are in my grounds in Cornwall, not in Devon, where I am only on a visit; and they certainly would not grow in the neighbourhood of Tiverton, which, for Devon, is very cold, and fully a month behind the south of the county.—*THE COLONEL.*

**Bitter Willows & Rabbits.**—Being engaged planting game cover last season, I was advised to try Bitter Willows, being informed that rabbits would not touch them. However, before they were planted twenty-four hours, I found them all barked by these depredators. Lord Chesham tells me he also tried Bitter Willows, which met with the same fate. I find nothing to escape them, but common Brambles with the Brake growing among them.—*R. GILBERT.*

## THE LIBRARY.

## HANDBOOK OF CHEMICAL TECHNOLOGY.\*

AMONGST the really useful books which occasionally appear amid those which daily issue from the press, few, if any, surpass this in the justice of its claims to merit. It is, perhaps, unfortunate that the editor has chosen a title which apparently relegates the work to the province of the purely scientific portion of the community, inasmuch as it conveys to the general public but a scant idea of the treasures of information which it contains respecting matters with which they are daily concerned. Let us, however, explain, in the words of the introduction, that "chemical technology" means "that branch of industrial science which treats of the processes and methods by which the nature of raw materials is usually altered," excluding all the operations of mere machinery. This being understood, we will say that, as an exhaustive and lucid exposition of the various processes whereby all the necessities of human existence which flow from this source are derived, the work before us has no equal. In the country of its author it has already reached an eighth edition, and, whatever stigma of tardiness may attach to us that we have not earlier availed ourselves of its teachings, will, we are confident, not long endure when it is better known amongst us. We cannot afford space to give more than an outline of its contents and its aim; and first we shall speak of its aim. This is to disseminate a true knowledge of the origin, preparation, and properties of the multitudinous substances which, in unaltered shape, make up various requirements of our present high-strung civilization. These are, for the most part, mysteries to the many, who, even if not very closely pressed, would be sadly puzzled to account for the appearance of such familiar accessories as sugar, soap, salt, and tobacco. To such we will only say that they will here find ample enlightenment on all matters of this sort, from the extraction and appliances of gold to the mixture for igniting the cartridges of breech-loaders or the making of matches.

The contents comprise eight divisions, viz.:—(1). Chemical Metallurgy, Alloys, and Preparations made and obtained from Metals; (2). Crude Materials and Products of Chemical Industry; (3). Technology of Glass, Ceramic Ware, Gypsum, Lime, and Mortar; (4). Vegetable Fibres and their Technical Application; (5). Animal Substances and their Industrial Application; (6). Dyeing and Calico Printing; (7). The Materials and Apparatus for producing Artificial Light; (8). Fuel and Heating Apparatus. The vast amount of particulars which are embraced under these heads may well be imagined, and of the details we shall say no more than that they have been elaborated with that honest accuracy which has ever characterised the German *surant*, whether in the philological researches of a Buttmann or the historical triumphs of a Niebuhr. To the editor and translator, those who know the difficulty of translating a work of a scientific character in a satisfactory manner, will accord a unanimous *plaudite*; few of those who have even a good conventional knowledge of a foreign language are aware of the embarrassments of such a task. He will, however, pardon us if we point out only one passage, which may be amended in a future edition, viz., that at page 19, fourteen lines from the bottom: "Thus the cylinders for rolling-mills can be so made that, while the surface is very hard, they are not brittle, *and, therefore, fragile*, because the interior consists of grey cast-iron." This, however, is but a crack in the toe-nail of the statue.

Catalogues of Bromeliads. — A noteworthy catalogue of Bromeliaceous plants grown in the Botanic Gardens of the University of Liège has recently been issued. It contains the names of upwards of 200 species and varieties, with the synonyms of each. It will, therefore, be found very useful to collectors and cultivators of these plants. The names of M. E. Morren and M. E. Rodenburg, attached to the catalogue, guarantees its accuracy.

\* "Handbook of Chemical Technology." By Rudolf Wagner, Ph.D., Professor of Chemical Technology at the University of Wurtzburg. Translated and edited from the eighth German edition, with extensive additions, by William Crookes, F.R.S. With 336 Illustrations. London: J. & A. Churchill, New Burlington Street, 1872.

## ARTIFICIAL CASCADES.

"The artificial," in a landscape, if not founded on "the natural," is always, more or less, a failure. When, therefore, it is sought to create a new feature in ornamental grounds, and to do it artistically, some natural model, of suitable character, should always be adopted as an original to be followed as closely as circumstances will admit; such a cascade, for instance, as the one represented in the annexed engraving, from a scene in "Nature Pictures,"\* might form an excellent model for an artificial waterfall.

It would, however, be useless to attempt the creation of such a cascade as the one suggested if the land to be treated were perfectly flat; for in such a situation water effects of quite a different character should be sought; but wherever there is a rise or slope of moderate elevation, if only of 10 or 12 feet of absolute height, a pretty and effective cascade may be created without difficulty, if a small supply of water can be made available on the higher level. By cutting a wide trench in the rising ground, from bottom to top, carrying the centre of the cutting back till the full height is reached, and the deepest part of the newly-created ravine becomes as steep as is desirable. There will then (supposing the positive height of the top of the undulation to be 15 feet above the level ground) be a slanting fall of 20 feet, or more if the slope be made more gradual; but the steeper the fall the more effective will be the result.

In cutting a ravine in a rising ground, natural rock may be found, which will answer the desired purpose, with proper management, better than any arrangement of masses of stone brought to the spot, and artificially disposed, however artistic the arrangement might be. There is, for instance, a rocky dell in the Birmingham Botanic Gardens which is a very pleasing exemplification of the advantage that may be taken of natural rock accidentally exposed during an excavation for such a purpose. In that case the earth was taken away from a rough outlying part of the grounds for the purpose of levelling and otherwise improving the more important portions of the gardens. The consequence was the creation of a hollow reaching down to the red sandstone, which underlies all that portion of Warwickshire, cropping out in some parts of the county in bold masses of rock. The hollow so created was used as a receptacle for swept leaves, rough prunings and croppings, and garden rubbish generally; but eventually, a member of the garden committee, anxious to add new attractions to the gardens, which combine pleasure grounds with the ordinary features of a botanic garden, conceived the idea that this rubbish-hole might be turned to ornamental account. It was therefore widened and deepened, with the intention of converting it into a fern glen, and with this view many rocky surfaces of fine form were laid bare, and a picturesque rocky valley formed. The sides and isolated masses of rock are now partially clothed with trailing plants, and in the more level parts with Foxgloves, Primroses, Squills, Violets, and other wild flowers, which display themselves in successive seasons of the year. Combined with the effect of suitable brushwood, these features tend to make what till lately was a piece of unsightly waste-ground one of the most attractive spots in the gardens.

Should rock of an analogous character to that which underlies the Birmingham Botanic Garden be found, in excavating such a ravine as that suggested above for forming the channel of a cascade, the desired effects would be produced, without any necessity for the introduction of artificial features; but if not, care must be taken that art shall create, in a broad and simple manner, the features that nature has failed to provide. The masses of stone must be of sufficient size to produce a massive effect, in proportion to the greater or lesser magnitude of the immediately surrounding scene. They must not, above all things, have the air of being *built up*, like the *stone steps* of the rock cascade in Hyde Park, which were intended to represent accidental ledges of rock, but which are as unartistic and as thoroughly conventional as the pretended "cataract of the Gauges," which, after many years of theatrical slumber, has just been reproduced at Drury Lane. On the contrary, a rugged tumbling together of big

rocks, jammed into almost impossible positions, as by some natural convulsion, should be imitated from some real scene; and if the would-be creator of such a cascade as the one under discussion be unprepared with studies of his own from scenery of the character desiderated, the main outline of the rocks shown in our engraving offers a good and sufficient model. To the right, the downward outline is grandly broken by a large

supported, like the pendent key-stones of ancient cathedral ceilings, by the surrounding mass of superincumbent stone.

Trailing Brambles and Ivy must mingle with the Ferns that are made to clothe the sides of the artificial chasm, as seen in the suggested model; and trees of moderate growth, such as Birch, Alder, and Maple, and well managed under-wood, formed of judiciously selected shrubs, must not be

Natural Cascade.

projecting mass at the base, from which portions have fallen into the bed of the stream, causing eddying rapids which might be closely imitated with the happiest effect; while on the precipitous declivity immediately above, a large and picturesque slab has fallen edgewise, the thin outline of which catches the light with sharp and sparkling effect. On the opposite side, several large masses impend over the chasm,

omitted. An essential feature in the composition is that the course of the cascade itself must be partially interrupted at irregular distances by rugged ledges, and, what may be called the key to the picture, the large boulder, rounded by the continual action of falling water, must not be omitted (as seen in the model), just visible in the mass of foam which its interruption creates. It is these last-named features which create the

hoarse yet musical voice of all cascades; a voice that never fails to attract the hearer to the spot where he expects to witness the cause of sounds which, whether in the restricted enclosures of a park or the grand scenery of the Alps, have a magnetic influence which invariably tends to attract the passer-by to deviate from his path in order to look more closely upon a scene which he has already pictured to himself in imagination from the sounds he has heard.

With attention to the principles suggested, and the necessary basis of a suitable site as to height and slope, however bare and unpromising it may appear before passing under the manipulations of the garden artist, such a scene as the one represented in our engraving may be easily reproduced with success.

NOEL HUMPHREYS.

## THE FLOWER GARDEN.

### NEW, RARE, OR NEGLECTED ALPINE PLANTS.

BY J. C. NIVEN, BOTANIC GARDENS, HULL.

*ANEMONE RIVULANIS*.—A native of the Himalayas, growing about 18 inches high, and producing its whitish flowers in abundance. A distinct and good perennial species, readily increased by seeds, which are freely produced.

*ANTIRRHINUM ASARINA*.—A pretty trailing plant, admirably adapted to hang over a projecting ledge of rockery, where, when kept dry, it will stand our ordinary winters. The flowers are yellowish, and about the size of those of the ordinary Snapdragon. Closely allied to it is *A. molle*.

*ARENARIA MULTICAULIS*.—From the south of Spain; resembles *A. balearica*, but has its leaves more ovate and ciliate, and its flowers elevated higher above the foliage and larger than that species; recently re-introduced by Mr. Maw, of Broseley.

*ARSEBIA ECHIOIDES*.—A charming plant from the Ural Mountains, forming a hard woody stem, from which its annual growths are made. Its flowers are yellow on their first expansion, but after a few days five dark spots appear near the throat of the flower, ultimately assuming almost a black appearance. It is exceedingly rare; in fact, we believe is only to be seen at Comely Bank Nursery in Edinburgh. It is very difficult to increase, as it rarely seeds, and cuttings will not strike.

*ASTER RAMOSUS*.—An abundant flowerer. Flowers rosy lilac, nearly as large as those of *A. alpinus*. A neat rock plant, from the Caucasus.

*ASTRAGALUS DASYGLOTTIS*, *Fisch.*—A native of the Ural Mountains; grows 8 or 9 inches high, and produces an abundance of bright lilac flowers; one of the finest and freest-flowering of the genus.

*ASTRAGALUS VAGINATUS*.—Twelve inches high; produces large heads of lilac and deep purple flowers; admirably adapted for either border or rockery, but somewhat scarce in cultivation.

*CAMPANULA SOLDANELLEFLORA* FL.—Sometimes named *C. rhomboides pleno*; but the former name is more appropriate, as the flower has all the appearance and beauty of its specific foster parent, associated with the light graceful character that is inseparably connected with the Harebell family. It is a plant of slender habit, with linear leaves. When growing strong, it attains a height of 15 inches. The flowers, being double, have a much longer duration than were they single. We have, however, never met with a single-flowered form that we could identify as the normal type of this plant.

*CRONILLA IBERICA*.—With glaucous foliage and decumbent habit, not rising 4 inches from the ground, and producing freely umbels of yellow blossoms. Somewhat similar in appearance, but much larger than our own familiar *Lotus corniculatus*. It flourishes admirably with its woody roots well bedded in rockery, and will cover completely 2 or 3 square feet of rock surface, when so placed.

*CYANANTHUS LOBATUS*. A native of the Himalayas, with large bell-shaped flowers, very similar in colour and appearance to those of *Roella ciliata*. It is rather impatient of too much moisture, but a plant that should find a place in all selections. It used to grow in perfection at Comely Bank, Edinburgh.

*DALIBARDA VIOLOIDES*.—A plant rarely met with, even in the most select collections. It grows about 2 inches in height, with somewhat reniform leaves, and white blossoms shaded

with the most delicate rose colour. It loves a deep, peaty soil; and, though a long-lasting plant, it is by no means of rapid growth.

*DIANTHUS CRUENTUS* AND *VAGINATUS*.—Both belong to the fasciculated or clustered flowered section of this genus, and are beautiful plants, well worthy a place in all collections. The flowers in the former, elevated on a stem from 9 to 12 inches high, are of a crimson scarlet, rich and intense; those of the latter are double the size, of carmine colour, nearly equal to *Calandrinia*, and only 6 inches high; it is a new and rare species, continuing in bloom for nearly two months.

*DONDA EPIDACTIS* (syn. *HACQUETIA*).—A most unusual form of the umbel-bearing plants, this is amongst our earliest bloomers. It grows only some 3 or 4 inches high, and though the blossoms individually are small, they are surrounded with a bright golden involucre that reminds one of the Burnet Saxifrage (*Chrysosplenium*), retaining its brilliant colour for nearly two months of the spring. It is a strong-rooted plant, likes a good stiff loam, and is perfectly hardy.

*ERODIUM CURVIFOLIUM*.—A good perennial species, producing flowers larger than *E. romanum*, the whole plant being more vigorous, and more decidedly perennial than that species.

*ERYTHRONIUM AMERICANUM*.—A species from North America, as its name indicates; narrower in foliage, with bright yellow pendent flowers; thrives freely in deep peaty soil; but rarely met with in cultivation. It stands in a somewhat similar relationship to *E. Dens-canis* that *Anemone ranunculoides* does to *Anemone nemorosa*.

*GERANIUM CRISTATUM*.—A trailing species, with peculiar crested appendages to its seed carpets. It is admirably adapted for rockery, covering fully 18 square inches; it is liable to smother more delicate plants, unless room be given to it. Flowers, lilac striated, very abundant, produced in May, and again in August or September.

*GYPHOPHILA PANICULATA*.—Although producing small flowers, as viewed individually, yet in the mass forming a globe-like head, say 2 feet in diameter. It is without exception the most perfect model of light, airy elegance that is perhaps to be met with in the whole category of plants; it seeds but very sparsely, but forms a woody, root-like stem, and the young shoots removed, when about 2 inches long, will strike freely.

*LILIUM FULCHELLUM*.—From South Western Russia, is even a more beautiful species than *L. tenuifolium*; slender in habit, the stem rises to a height of 12 to 15 inches, crowned at the top with upright (not pendent) deep orange blossoms, slightly marked with black dots; not by any means common in gardens, but a distinct and most desirable species.

*LINARIA PLEOSA* AND *HEPATICEFOLIA* are somewhat allied species, although perfectly distinct. They are both so dwarf as to defy their height being characterised by inches. In fact they grow flat on the ground and produce their lilac blossoms just raised above the foliage very freely.

*LINUM FLAVUM* (syn. *TAURICUM*) is a distinct herbaceous alpine, all the previous year's growth dying quite away during winter, a fresh growth rising in early summer, from a substantial woody, underground stem. It grows 9 inches high; flowers of a more decided golden colour than those of either *L. arboreum* or *campanulatum*. Well worth cultivating either for border or rockery purposes.

*ENOTHERA PUMILA*, as the name would indicate, is of diminutive size, growing about 4 or 5 inches high, forming dense, compact tufts, and flowering abundantly. It possesses a beauty which is much enhanced by its modest simplicity.

*ENOTHERA RIPARIA*.—Considerably more vigorous in growth, but with a somewhat similar habit to the foregoing. This species, flowering freely and continuously, has been introduced into our flower-gardens; but, though scarcely adapted for that purpose, it forms a beautiful rock or dwarf border plant. Its flowers are canary yellow, and nearly 1½ inch in diameter.

*OSOSMA TAURICA*.—A Boraginaceous plant, producing an abundance of tubular, somewhat ventricose, canary-coloured flowers, on long racemes; is a noble rock plant. It should be planted on an elevated knoll, so as to allow its branches to hang over the surrounding rocks. Though perfectly hardy, it is somewhat impatient of water during winter, and if growing very vigorously, is liable to rot off.

(To be continued.)

## VIOLET CULTURE.

VIOLETS are no longer, as they were in our childhood's days, the harbingers of spring, but they come upon us with their innocent and welcome faces in the cold nights of autumn, and cheer us with their delicious odour when all around is dark and dreary. For mere out-door growth and for winter blooming the Russian is the most useful variety, as you may sweep the snow away and gather it fresh. The Czar, a more recent variety from the Russian, is much larger—more than double the size—and grows upon long foot-stalks; but it is not so hardy, cold cutting winds scorching the leaves up very quickly, while under the same circumstances the Russian will not be injured at all. The Russian Violet is grown very extensively for the supply of the London markets, though the Czar for spring work is beating it, especially when grown in sheltered situations; then the blooms come up with unusual vigour. Now, if we seek the Violet in its natural habitat, we find it nestling upon sheltered sunny banks at the foot of hedge-rows, and upon good though not perhaps rich soil. Mr. Ingram, of Belvoir, who grows and gathers Violets by the bushel throughout the winter, upon a soil where years back it was said Violets could not be grown, finds it advantageous to imitate the natural conditions; and hence he either throws the ground into slight ridges sloping to the sun, or plants upon well enriched ground, where the under-lying roots of deciduous trees control and regulate the deluge of water in a dripping season. In such a situation he finds the growth of the plant to ripen properly, and a fine supply of flowers to be the consequence, while in rich and open soils leaves take precedence of the flowers. The routine cultivation of the Violet consists in dividing the plants in April or early in May, divesting them of all small runners, and planting them upon well-enriched ground in patches of two or three strong plants at a foot apart. Through the summer the ground is kept free from weeds, and the plants are frequently watered and kept free from runners. In this manner they form close compact plants with strong crowns, from which an abundance of flowers is produced. Violets, more especially in the open garden, are very subject to the attack of red spider. The best remedy for this pest is copious watering with the garden engine, by which the insects may be dislodged, and then dusting the plants, especially on the under sides of their leaves, with sulphur. Two or three dressings in the course of the season will generally be sufficient to keep the plants clean; and, if soap-suds be added to the water when washing the plants, it will not be less effective.

The best place in which to bloom the Violet early and regularly is under the protection of glass in a pit or frame. In some gardens glass is used very extensively for that purpose, as many as thirty or forty lights being employed. Supposing the pits to have carried a crop of Cucumbers or Melons through the summer, the best plan is to clear away the soil, and, if the heating material is quite spent, to remove the most decayed parts and add sufficient fresh leaves to create and maintain a gentle heat for a lengthened period. For this purpose a foot or 18 inches of fresh leaves may be sufficient, putting them in a layer at the bottom of the pit, and covering them with the partly spent material. This should be done not later than the first week in October, then treading the mass quite firm, and filling the pit so full, that, when a six-inch layer is added, the surface of the bed will not be more than 6 inches from the glass. The soil of the old Cucumber bed, to which a third of fresh loam may be added, will be suitable material to plant in. In removing the plants, retain a fair proportion of soil with each, divesting them of their runners as you proceed with the work; and as you plant, place the plants sufficiently close together to have a compact mass without the foliage being crowded. Fill the soil in firmly between the plants, give a good soaking of water, both to wash the foliage and soak the roots, and the work is done. It may be necessary to shade the plants for a few days until they make fresh roots; but then the more fully they are exposed to the sun through the day, putting the sashes on at night, the better. Once properly soaked, but little water will be wanted until after Christmas; indeed, it is necessary to keep the foliage dry, or the flowers will damp off. At the same time, keep the soil between the plants clean and healthy by removing weeds and decaying leaves, and by

frequently moving the surface with the hand or hoe. The subsequent treatment will be comprised principally in ventilating and gathering the crop. It will be wise to protect the plants from frost, and for that purpose the pits must be covered down with mats and other material, according to the severity of the weather. Should water be required, apply it warm, and pour it carefully between the plants, choosing a dry, sunny day for the purpose, so as to get the surface quickly dry. This will be the plan up to the commencement of the new year; but then, as the sun gains strength, more liberal treatment may be indulged in. The plants may be syringed on sunny mornings twice or thrice a week, and they may receive an occasional soaking of weak manure water, which will impart great strength to the flowers. This is best prepared from soot and guano; but it should be quite clear at the time it is used, and if the chill be taken off so much the better. The preceding treatment relates mainly to the Neapolitan and Czar varieties. Both, of course, will bloom in the open air, the foot of a sunny wall being the best place, and both will make nice beds in a suitable situation.

W. P. A.

## THE DOG'S-TOOTH VIOLET.

THIS obtains the name of Dog's-tooth Violet because of the long fang-like tuberos roots that are white in colour like a tooth. Apart from the lovely flowers the plant produces, the leaves of the red variety especially are very handsomely marked. As soon as the ice and snow which hold the earth in bondage in February are dispersed by the warm breath of spring, it issues forth, first unfolding its handsomely marked leaves, and then its charming flowers, borne singly on stems 4 inches to 6 inches high, and drooping gracefully. The flower is surpassingly lovely, and it comes into bloom with the Snowdrop, Hepatica, and spring flowers. A moist peaty soil, with which has been mingled a good deal of sand, appears to suit the Dog's-tooth Violet as well as any. Shady spots are generally recommended for its culture, but it is frequently met with in positions fully exposed to the sun, and doing well. In some localities it appears difficult of cultivation, mainly from the unsuitability of the soil; in others just the opposite results—it flourishes with all the vigour of a native plant. In the midland districts, where there is more humidity pervading the atmosphere than in the south, it scarcely fails to do well. In addition to the imported species, which bears rosy-purple or lilac flowers, there are also varieties of it, such as *Album*, white; *Purpureum*, purple; and *Roseum*, rosy. These have been selected, because showing a certain distinctness of colour, and have been found to retain it when in cultivation. There is a distinct large-flowering type of the original species, known as *Major*, in which the leaves and flowers are both larger than is usually seen. The purple-flowering varieties have the green leaves handsomely marked with reddish-brown, and when at their best are more attractive than those of some handsome-foliaged plants that are sold at a high price. The white-flowering variety has the leaves blotched with a kind of whitey-brown colour. There is also an American species, named *E. americanum*, which bears yellow flowers, and blooms a little later in the season. A variety of this is also obtainable, having brown spots at the base of the flowers. It is recommended that every third or fourth year the bulbs be lifted, separated, and replanted.

Quo.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Ranunculus cortusefolius.**—This fine plant, a native of the Canary Islands, bloomed beautifully here in the early part of last summer. It is perfectly hardy, but requires a shady, sheltered nook, and thrives well in peaty loam. In the second supplement to "London's Encyclopedia of Plants," it is said to be the handsomest of all the Crowfoots. It is certainly a very distinct and beautiful species, which only requires to be known to be appreciated.—J. WHITTAKER, *Mortley, Derby.*

**Dianthus barbatus atropurpureus.**—This is a long name for a form of our old acquaintance the Sweet-William; but it botanically expresses the colour and the foliage of a variety that is grown in West Middlesex. Its merit is the character of its foliage, which is very large and robust, and is of a deep coppery hue, almost as effective in a mass as Dell's Crimson Beet; the bloom is of a crimson red colour, but the quality is indifferent. As a winter decorative plant it would prove most useful, as its peculiar hue is most predominant from the end of September until the end of March, and it would be effective a month later if the young shoots were pinched out.—A. D.

**Crocus Enemies.**—The Crocus destroyers which your correspondent Mr. Newman says have been so troublesome to him, and which he cannot discover, are the common house-sparrows, which have cut off numbers of mine just in the manner he describes; and if he watches in the morning or at any time when the sun is shining, he will see these mischievous little tormentors at work. He will also observe that they do not eat or seem to make any use of the blooms, but as soon as one is cut off will go to the next, and so on. Numbers of my Crocuses are spoiled in this way every year, particularly the yellow ones.—A. H., *Upper Norwood.*

## GARDEN PORTRAIT GALLERY.

JEAN DE LA QUINTINIE.

BY NOEL HUMPHREYS.

JEAN DE LA QUINTINIE, Director-General of Gardens to Louis the Fourteenth, one of the most distinguished heroes and worthies of French horticulture, was an accomplished scholar, and of gentle birth. He was highly esteemed by his contemporaries, of all classes; and Perrault, in his magnificent work entitled "Hommes illustres qui ont paru en France pendant ce siècle," places La Quintinie among the number. In that magnificent work, illustrated by a series of portraits which are masterpieces of the engraver's art of the period, that of this eminent gardener holds a conspicuous place by the side of the Racines, Corneilles, and Turennes of the "grand siècle."

Jean de la Quintinie was born at Chabannais, in the district of Angoumois, where his paternal home is still pointed out to visitors as one of the most interesting monuments of the place. He was sent to Poitiers to be educated, and distinguished himself in *belles lettres*, philosophy, and jurisprudence; which last he studied as the basis of the profession which had been selected for him by his parents, notwithstanding his strong predilections for horticultural and agricultural pursuits. On proceeding to Paris, with a view to commencing his legal career at the bar, he at once received his diploma as an advocate. Being gifted by nature with an agreeable and ready flow of eloquence, he was at once successful, and but for a series of fortuitous circumstances, he might have continued to waste his powers in the barren victories and *tracasseries* of litigation. Having, however, abandoned the active prosecution of that career for a time, in order to accept a lucrative and advantageous appointment as private tutor to the eldest son of M. Tambonau, president of the *Chambre des Comptes*, events so moulded the direction of his career that he never seriously resumed his legal pursuits. The appointment led to a prolonged tour in Italy with his pupil, during which his original taste for gardening and horticulture became more actively developed. Even while busy with the dry drudgery of the law, he had found time to read all the ancient authors who had treated of gardening or agriculture—Virgil, Varro, Columella, and others; and in the course of the Italian tour with his young pupil, he lost no opportunity of indulging his taste in that direction, by visiting the magnificent villas and gardens of every kind in that country, and especially studying the Italian methods of agriculture, and the cultivation of fruit trees. During this journey his observations led him to form many theories which he afterwards reduced to practice with eminent success. His first actual experiments were carried forward in the gardens attached to the new residence of his patron, M. Tambonau. This mansion, or hotel, as the French prefer to call such an abode, was erected in 1644, on ground purchased from the University of Paris, and was the first house of the present Rue de l'Université. The gardens which then surrounded it were of considerable extent, and their entire management was entrusted to the tutor of the younger Tambonau. La Quintinie, profiting by this opportunity, not only established a noble fruit and flower garden for his patron, but also found time in the midst of the classical and legal studies necessitated by the education of his pupil, to carry out a number of interesting experiments which he had long meditated. His theories concerning root pruning, on the transplantation of trees, and branch pruning were much in advance of his day, and were so severe in some cases, that contemporaries, jealous of his great success, called him the mutilator instead of the cultivator of trees.

He was, however, in no way offended by their incredulity; and instead of resenting it, sought rather to inspire them with his own love of knowledge, and his experimental methods of arriving at it, in order that they might prove for themselves the value or worthlessness of his theories. He had no secrets from true lovers of horticulture. All the most cherished results of his ingenious hypotheses and endless experiments being freely communicated: for he placed the progress, spread, and general practice of his favourite art far above any private gain he might have secured by keeping his discoveries to himself. Animated by such views, he established an active correspondence with horticulturists in every part of Europe

where gardens were cultivated, and travelled through France, Belgium, Holland, Denmark, and England for the purpose of investigating the methods of culture pursued in those countries. The King of England (James II.) made him tempting offers with the view of retaining his services, and pressed him to accept a suitable appointment; but his attachment to his own country prevailed, and he returned to France, but not till he had established many valuable and lasting friendships; and he continued to the end of his life to correspond with many English noblemen and scientific men. It is stated by his French biographers that those letters were collected and published; but as no trace of such a publication can be found, the assertion is possibly a mere conjecture. Only one letter of La Quintinie's to an English correspondent is now in existence, and that one has never been published. It is to be found among the records of the Royal Society, and was addressed to Mr. Oldenbourg, then Secretary. The French biographers were equally wrong in denying the translation of La Quintinie's works into English by the celebrated John Evelyn; stating that the work on gardening translated by Evelyn was not that of La Quintinie, but of another and very inferior French author on horticulture. The answer to this groundless assertion is, that there is now in the office of THE GARDEN a copy of Evelyn's translation of La Quintinie, which was published very soon after the appearance of the original work.

La Quintinie was received on terms of equality by the highest nobles of France; his conversation upon all subjects connected with science and literature being highly appreciated. The celebrated Prince of Condé, who was an enthusiastic gardener and agriculturist as well as a great soldier, delighted in his companionship, as did many other eminent men of the time, of various ranks and professions. When his fame as a scientific horticulturist reached the ears of the king, Louis XIV., he was sent for to Versailles, to direct the preparation of sites suitable for the growth of fruits and vegetables, and by such an addition render complete the great series of ornamental woods and pleasure-gardens planned and carried into execution by Le Notre, who had so triumphantly succeeded in blending art with nature, architecture with foliage, sculpture with flowers. The king told him, on his arrival, that he had then become most anxious "to add the useful to the beautiful," declaring that no other than Monsieur de la Quintinie should assist him in that agreeable task.

The site of the old Jardin Potager which had existed since the time of Louis XIII. was found to be far too small for the existing requirements, and was moreover objectionable both on the score of aspect and the natural sterility of its soil; it was, indeed, found to be so entirely unsuitable that some proposed to have the royal fruit and vegetable gardens established at St. Cloud. But this proposition was overruled by La Quintinie, who strongly urged the king not to allow the most magnificent palace in the world to remain without gardens on the spot capable of furnishing the royal table with all the requisite luxuries of fruits and culinary vegetables; and this view eventually received the royal sanction. The creation of extensive fruit and vegetable gardens at Versailles being thus determined upon, La Quintinie was not long in fixing upon a suitable situation, and the position he selected possessed far better soil than any other site in tolerably close proximity to the palace, while the aspect was almost all that could be desired.

His excellent plans were, however, frustrated, and he was compelled to change his intentions entirely, in consequence of a mere Court caprice. He and his plans, and the character and situation of the new gardens were frequently the subject of conversation among the courtiers who more immediately surrounded the King; and one day a brilliant *courtige*, returning from a day's hunting in the forest, halted for a short space on the slope of a rising ground, at some distance from the grand new palace, when one of the ladies of the hunting party, struck with the pleasant prospect, declared that the spot on which they were assembled was the very one upon which *ce cher De la Quintinie* ought to establish his projected gardens; and the lady in question being beautiful and, consequently, popular, her views concerning the matter in question were very generally supported, and met with Royal approba-

tion. The result was that some thirty acres of about the worst land conceivable had to be accepted by La Quintinie in lieu of the site he had himself selected; yet, in order to show what science could effect under the most disadvantageous circumstances, he at once commenced the arduous task, like a true Frenchman, with smiling acquiescence, though he afterwards confessed, in considerable detail, and with some

to form the basis of an entirely artificial super-soil created with vast cost and ingenuity by the gardener. The end of the business was, that a fine garden was established; but, at a cost of 1,800,000 francs, while, on the site originally selected, the necessary outlay would not, according to La Quintinie, have been more than one-sixth of that sum, namely, under 300,000.

In this undertaking, with the object of obtaining as great

JEAN DE LA QUINTINIE.

humour, the almost impossible character of the task that had been thrust upon him. The soil, he said, was of that peculiar nature that, during summer, it condensed itself into hard masses, separated by innumerable arid cracks, while in winter it dissolved itself into a thick, sloppy *soupe*. It was, in short, a soil that could neither be enriched nor improved, but had simply

an extent of wall as possible for Peaches, Apricots, Pears, Figs, Grapes, and choice Plums, he first enclosed a space of 12 acres with a fine high wall; surrounding it with eight walled enclosures of about one acre each. But with all this luxury of wall, it was only his very choicest fruits that were trained; not even the Figs were treated to this luxury, except

one or two of the more tender kinds, though the Fig was the favourite fruit of the King. On these matters that great personage himself, who said, "*L'état c'est moi*," delighted to talk, and would often slip away from wearying discussions on matters of State with Colbert or Turenne, to have a pleasant chat with his learned gardener, in whose favour and interest he created a new official appointment—that of Director-General of all the royal fruit gardens. The hours spent with La Quintinie in discussing the best methods of growing Peaches and Figs in the highest perfection were said to be the pleasantest moments of the royal leisure.

The fruit then served at the regal banquets was acknowledged to be the finest in Europe; and instead of furnishing forth useless quantities as formerly, when vast pyramids of Melons, Pears, Peaches, and Grapes were heaped upon the royal tables with barbaric profusion, only small and delicate baskets, furnished with the very choicest specimens, were to be seen—the honour to the gardener consisting in the simple fact that the baskets invariably went back to him empty. It is one of the honours of La Quintinie that Molière, in one of his plays, has alluded to the magnificence of his Melons. The King caused a spacious and comfortable house to be built expressly for his distinguished gardener, and when he died (in 1696) sent for his widow, and kindly taking her hand, said, "*Madame, nous venons tous les deux de faire une perte que nous ne pourrions jamais réparer.*" In addition to the gardens of Versailles, La Quintinie established the fruit and vegetable gardens of Chantilly, for the Prince of Condé; those of Rambouillet, for the Duke of Montpensier; those of St. Ouen, for M. de Boisfranc; those of the Château de Sceaux, for the great Colbert; and those of Vaux, for the minister Fouquet.

His manuscripts were collected by his only surviving son, M. l'Abbé de la Quintinie, and published in a handsome volume soon after his death in 1696. It formed at the time an invaluable and complete code of all that was then known of the most advanced methods of horticulture, and was translated into nearly all the languages of Europe. The original portions of the work are highly valuable and instructive even at the present day; but some years after its first publication it became the prey of greedy booksellers, who, in order to increase its bulk and price by swelling it into two volumes, added a mass of nearly worthless matter which La Quintinie would never have acknowledged, and which was in fact quite unworthy of him.

In the last chapter of the original work the culture of Oranges is carefully treated of, and the author asserts that, with the application of the proper principles, success is much easier than is generally conceived. It is a chapter well worthy of study at the present time by would-be Orange-growers. Some of his paragraphs upon the useless multiplication of named varieties of fruits and vegetables then in general use are somewhat humorous, especially one concerning new kinds of Pears, of which he gives a long list, which he says are all very inferior to the old kinds, adding a second list of vaunted new sorts which he says are "so execrable that he implores his friends not to attempt to grow them." His list of the best Peaches then known is very copious, and he places above all, for exquisite texture and high flavour, *la petite Violette Hâtée*.

Santeul composed a Latin poem, entitled "Pomona," in honour of La Quintinie, in which are many lines that might vie in metre and poetic eloquence with the very best of modern Latin verse-making; and Perrault, a member of the famous Académie, one of the "immortal forty," has left a French Idyll inspired by the great horticulturist which is very far from being without merit. The opening and the close of this little poem in honour of gardeners and gardening may be thus rendered in English, in which form, however, much of the terse neatness of the original has necessarily evaporated.

While some sing our warriors, with vaunting elation,  
Whose reign is death's reign, and fair earth's desolation—  
Grant me Muses! and scenes of the soil's rich increase  
To sing of the Hero of gardens,—and peace.

\* \* \* \* \*

With the heaven-given light that shone down at thy birth,  
Thou hast sought to enrich and embellish the earth,  
And at last, by thy learned and elegant pen,  
Hast transmitted thy art to new races of men.

## PUBLIC GARDENS.

### OUR NATIONAL HERBARIUM.

WILL you, by giving to the public the accompanying rejected letter, permit me to secure through your pages an act of justice which has been denied me by one of your contemporaries? To make the letter intelligible I must give a short historical preface.

I had occasion to correct some errors in a statement made by Dr. Hooker published in *Nature*. My letter was written on the 2nd of December last. Its publication was delayed a week, and when it appeared there was appended to it a reply by Dr. Hooker, dated the 3rd of December, showing that my manuscript had been at once sent to Dr. Hooker to be dealt with. This reply contained statements which a careless reader might suppose went to show that I was mistaken. I set the matter right in a reply I wrote on the 16th of December, the proof of which, besides being sent to me, was sent to *one* whose adverse criticism induced Mr. Norman Lockyer, the editor of *Nature*, to refuse its publication. I protested against this, and showed how erroneous the criticism was; this remonstrance compelled Mr. Lockyer to give up the criticism as a ground for refusing me justice, and to assume to himself the responsibility for thus acting. The reasons he then gave showed a complete misapprehension on his part of the matters in dispute; but the last and strongest of them was of a kind that I can only venture to put before your readers in the words of Mr. Lockyer himself: "I cannot lend myself to appear to question the truth of a statement made by a man of science of Dr. Hooker's eminence." This was of course final. I had not attained to sufficient eminence in science to secure me from error; my statements are called in question by Dr. Hooker in the pages of *Nature*; and I ought to have nothing to complain of.

Every week the printed letters in *Nature* are prefixed by the statement, "the editor does not hold himself responsible for opinions expressed by his correspondents;" and in his letters to me he claims for himself "fairness and plain-dealing." Nevertheless, while rejecting my courteously worded letter (the proof of which I enclose) he has, in recent numbers of his periodical, permitted two of his correspondents to make offensive mis-statements affecting the botanical department of the British Museum, which of course remain unquestioned as far as I am concerned.

*British Museum, March 17.*

WM. CARRUTHERS.

The following is the rejected letter referred to by Mr. Carruthers:—

TO THE EDITOR OF "NATURE."

Dr. Hooker is mistaken when he says\* I implied that he suggested the supplying the British Museum with "worthless duplicates" from Kew. These words are plainly my own estimate of the materials which, in the scheme of Dr. Hooker, are intended to constitute the London Herbarium; and I maintain that the duplicates would be worthless to the Kew collection, else they would not be parted with, and they would also be worthless for any uses in scientific botany when forming the only materials of a herbarium at the Natural History Museum at Kensington. Anyone wanting information, whether "geologist, botanist, amateur, or other resident in London," must have parted with his senses if he stopped at Kensington to consult the *rejetamenta* of Kew, placed by a subordinate as easily as "putting books on a shelf," retaining all the original errors in naming, and without any provision to prevent the continual increase of such errors necessarily resulting from the progress of scientific knowledge, and did not continue his journey five miles farther to the "great scientific working herbarium to which all botanists should come."

Dr. Hooker is equally mistaken in saying that I state that none of the collections distributed at Kew have been sent to the British Museum. I definitely spoke of the "collections made at the expenso of the British Government;" and my statement is absolutely correct. The only set of plants received here from Kew since 1853, when it was set up as a rival to the British Museum (excluding, of course, the "Erebus" plants, the distribution of which began in 1815) and privato collections which have been purchased from their owners) is the very valuable series of Hooker and Thomson's Indian plants, amounting to 6,966 species, which were presented in the names of these two gentlemen, and for which they were thanked

\* *Nature*, Vol. VI., p. 103; Dec. 12, 1872.

as the different instalments were delivered. Dr. Hooker's complaint at not receiving duplicates in return for this gift has some foundation, but it is strange that, as far as I know, this is the first time he has ever expressed a wish to have any of our duplicates. My assertion, and my complaint too, is, that of the collections of plants made at the national expense, and distributed from Kew, not a single set has been sent to the National Herbarium, though sets of all of them should have come here not as a gift, like the plants of Hooker and Thomson, but as a right.

I have again read over the official report of Sir Wm. Hooker for 1853, and am satisfied that the use I made of the extract is justified. On the other hand, I can find no statement to the effect that the work of the Garden had been carried on ever since Sir Wm. Hooker became director by means of his own private herbarium, nor any of the qualifications as to time, &c., given in Dr. Hooker's letter. It is a remarkable corroboration of my view of the case that, when Sir Wm. Hooker himself first offered his herbarium and library to Government, the then First Commissioner of Works refused the offer, on the specific ground "that the application of a Hortus Sicens and library to the naming of the new plants received at Kew had been effectually and satisfactorily performed through the Botanical Department and Library of the British Museum."

The statement made by Dr. Hooker that a large Herbarium was in constant use at Kew in the time of the Aitons, opposed as it is to Sir Wm. Hooker's repeated declarations as I read them, and certainly to the documentary evidence I published in your last issue, as well as to reliable information which I possess regarding the state of Kew at the time referred to, if persisted in, should be substantiated by evidence.

I may add that I have been drawn into this correspondence, and will, if necessary, continue it, only from a sense of my duty as Keeper of the National Herbarium here.

WM. CARRUTHERS.

British Museum, Dec. 16.

## WORK FOR THE WEEK.

### PRIVATE GARDENS.

**Conservatories.**—Indoor plants, though backward this spring, on account of want of sunshine, are, nevertheless, now starting freely into growth, and must, therefore, be encouraged. Deciduous shrubs and climbers still unpruned must now receive that attention, in order to prevent unshapely growth; and all evergreen shrubs may yet be safely pruned, and, if necessary, transplanted or repotted. Stake plants in pots as requisite, bearing in mind, however, to use as few for that purpose as possible. As the young shoots lengthen, they should be tied out at once to the principal supports. In repotting carefully disentangle the outside roots, for plants shifted in a pot-bound condition never succeed satisfactorily. Good substantial loam, skimmed off the surface of a rich pasture, and stacked for twelve months previous to use, with alternate layers of manure, forms an excellent compost for most plants. Wash all sashes requiring that attention, paint any rafters or other wood or iron work that seems to need a coat of paint, and scrub off any coniferæ or green slime that may collect on the stages. No dirty pots, too, should be used in potting, and the pots in which plants not to be shifted this spring are growing, should also be well washed, and the surface soil cleaned, and, if necessary, a fresh dressing applied. Newly-potted plants should be kept in the warmest corner of the house for a time, and excluded from cold draughts, but to plants in active growth plenty of air should be admitted, and abundance of water given. Maintain the gaiety of conservatories and other show houses by means of *Hoteias*, *Spiræas*, various sorts of *Prunses*, *Dentzias*, *Lilacs*, *Rhododendrons*, *Weigelas*, and *Roses*, brought from forcing houses. Keep up a good succession of *Hyacinths*, *Tulips*, *Narcissi*, and *Crocuses*, and for late bloom remove some of the latest of these to a cool house or pit, with a north aspect. Introduce *Mignonette* from frames, and, if necessary, sow a fresh supply in pots for summer blooming. *Rhodanthes* are charming plants, both for summer and autumn decoration; therefore sow some at once in 4 and 6-inch pots, or in pans, and, when ready, prick the young plants out into pots, keeping them near the light, and pinching them at the third joint.

**Forcing Houses.**—These when not wanted for flower forcing may be usefully employed for Cucumber growing. At present, however, keep them supplied with successions of *Lilacs*, *Spiræas*, *Dentzias*, and similar plants. Cuttings of *Coleus* struck early should be potted as they require it, pinched at the third joint, and the plants should be kept near the light. *Iresines* form attractive summer objects in conservatories, therefore treat them like *Coleuses*. The general stock of *Begonias* should now be potted and started into growth. *Caladiums* started in small pots should be shifted into larger ones before their roots become entangled. Continue to force

*Lily of the Valley*, place the plants that have been forced under the stages of the greenhouse for a time, and after that plant them out, where, if they are well cared for, they will in two years make good plants for forcing again. Some plants of *Lilium auratum* should be introduced to this house for blooming in May. In making up baskets for suspending in the conservatory keep them in the forcing house until they are in active growth, when they may be gradually hardened off, so as to withstand the cooler temperature to which they are to be subjected. Bring on plants of *Dendrobium nobile* where an early bloom is required, and place those for late use in the greenhouse. Keep up a young and healthy stock of *Fuchsias*, *Heliotropes*, *Petunias*, *Balsams*, *Cockscombs*, *Hebeclimiums*, *Callas*, *Schizanthuses*, and other plants for early blooming; those treated more hardily flower later.

**Stoves.**—Young and tender growth must now be protected from bright sunshine, especially when the leaves are damp. Put a few neat stakes amongst the leaves of the earliest started *Caladiums* to keep them from getting broken. Keep the young stock of *Palms*, *Cycads*, *Dracenas*, *Ixoras*, *Crotons*, *Pavettas*, &c., in a warm moist temperature; and, if a brisk bottom heat can be given them, so much the better, as in that case the plants start more freely into growth, and develop their foliage in greater perfection than they otherwise would do. Repot the stock of *Alcotasias*. Plants belonging to the macrorhiza section of that genus like a good substantial loamy compost; whereas those belonging to metallic delight in an open turfy soil. They like plenty of water, both at the root and in the atmosphere; indeed, *A. metallic* and *Marantas* would thrive set on inverted pots in an aquarium—i.e., if the bases of the pots were just above the water. *Cyanophyllums*, *Sphaerogynes*, and *Medinillas* also enjoy a similar position, and the large and magnificent foliage they produce under such circumstances amply repays any attention they may receive in that way. Put some *Tradescantias* of the discolor section in 4 and 6-inch pots, and keep them for a time in a brisk moist temperature, when they will make excellent flowering plants. Start *Clerodendrons* of the fallax, fragrans, and *Kempferi* section, and give the climbing ones plenty of string to support their growing shoots. As soon as *Crinums* have done flowering, repot them in a good substantial loam mixed with some well-decomposed manure. They may be bloomed in the same pot for two or three years in succession if the specimens are large; but, in that case, manure water must be given them. *Centradentias* make useful winter plants, if propagated from cuttings now, and well attended to during the summer. Keep *Brexias* free from scale, and *Ixoras* from mealy bug. *Allamandas* must now be kept in active growth, *A. nobilis*, *grandiflora*, *Hendersonii*, *cathartica*, *Schottii*, and *Aubletii*, are amongst the best. *Meegeravia dubia* is a useful plant; it will cover a stone or brick wall, grow on the wooden rafters on the north side of a stove, or make a nice covering for the stumps of tree Ferns; indeed the *Maregravia*, dwarf climbing *Piceuses*, *Eschynanthuses*, and similar plants, thrive admirably in such situations. Cut back plants of *Scutellaria Meeiniana*, and pot and start them into growth. *Cissus discolor*, a plant which well deserves every encouragement, enjoys heat and moisture when growing, and it is rather partial to a slightly shaded nook. Cut back the old plant of it close to the main trunks or shoots, and induce them to start afresh. Divisions of the cut-away shoots strike freely, and form nice little plants for suspended baskets, or for pot trellises. *Torenia asiatica*, various sorts of *Eschynanthus*, *Coccoypselum discolor*, *Panicum variegatum*, *Hoyas*, *Selaginellas*, some Ferns, and *Dracenas* for centre-pieces are suitable for basket-work; but if a little extra shade can be afforded, many other plants, such as the beautifully-leaved *Philodendron Lindenii*, *Pothos argyrea*, different kinds of *Cissus* and Pitcher plants, may be effectively employed for the same purpose.

**Kitchen Garden.**—The value of trenching and ridging ground in winter has been made fully apparent this spring, for while plots that were dug only have been hardly workable, the ridged ground crumbled down like dust, and, indeed, it is upon such ground we depend for our early Cauliflowers, Lettuces, Peas, Potatoes, &c. Sow a little *Salsafy*, *Scorzoner*, and *Skirret* in lines about a foot apart; the first or second week of next month is the general time for sowing these; but in late localities they should be sown earlier. Of the three, *Scorzoner* is the greatest favourite. Sow a full crop of *Savoys*, *Broccoli*, and *Brussels Sprouts*; sow also some seeds of *Asparagus* in lines 18 inches apart; likewise successional crops of *Radishes*, and occasionally some *Lettuces*, both *Cabbage* and *Cos* kinds. Also plant out winter-raised or protected *Lettuces* between Cauliflower plants, or transplant a full crop over *Seakale* or *Horseradish* plantations. Finish transplanting *Onions*, and, if not already done, sow the summer crop at once. Sow *Round Spinach* between rows of *Peas*, or, in some other places, in quantity sufficient to meet the demand; sow also some of the *New Zealand Spinach* in heat for a summer and early autumn crop; this variety often affords fine

succulent leaves, when ordinary Spinach cannot be had. Of Carrots sow a full crop in deeply-trenched ground, which should get a good dressing of fresh air-slacked lime. Sow some small kinds of Turnip in lines a foot apart, or in beds 4 feet wide on warm, light soil. Earth up and stick Peas as they advance in growth; any exposed to cutting winds should have the assistance of a few evergreen branches to break its force. The following are first-rate sorts for sowing about this time, viz., Champion of England, Laxton's Prolific and Quality, Veitch's Perfection, Dixon's Favourite, McLean's Best of All, Prince of Wales, Wonderful, Fairbeard's Surprise, Victoria Marrow, Knight's Tall Marrow, British Queen, and No Plus Ultra. Transplant Cabbages as required. Lift, divide, and transplant pot herbs, and sow in a frame some for planting out in May or June.

#### NURSERIES.

**Outdoor Department.**—Now that the sale of deciduous trees is all but over, means should be taken to utilise the ground on which they stood. Let it be levelled and manured, and then line in younger plants, seedlings, and layers separated from last year's stools; lines about a foot apart are sufficient for the smaller kinds. The plants lifted between the end of October and now are commonly sized, and the smallest are laid in thickly in niches in any odd corner until now, when they are transplanted. Conifers and other evergreens may be transplanted until the end of May. The layering of deciduous trees should now be performed; last year's layers having been separated, dressed, and transplanted, the ground about the stools should be manured and dug, and shoots formed last season layered, at the same time cutting their points back to about 6 or 10 inches above ground. Autumn is the proper season for layering evergreens, and spring for layering deciduous trees. Of the latter the following are kinds most commonly propagated in this way, viz., *Rheedia monostachya*, *Desmodium pendulifolium*, *Potentilla fruticosa*, *Cydonia japonica*, *Rhus Cotinus*, *Spiræas*, different sorts of *Berberis*, *Cornuses*, deciduous *Magnolias*, *Philadelphus*, *Dentzias*, *Syringas*, *Maples*, *Nuts*, *Planes*, *Brooms*, *Limes*, *Calycanthus*, *Paradise stocks*, *Ghent Azaleas*, and others. Climbers and other plants in pots plunged out of doors are lifted, the protruding roots cut away, and the plants staked, potted, and tied neatly.

#### MARKET GARDENS.

Now that bright weather has set in, crops which have hitherto been somewhat backward are beginning to start into active growth. In the last week of March last year, good Asparagus was cut from the open field, but this year growers do not expect to cut any before the 1st of May. This will reduce the Asparagus season to some six or seven weeks' duration, whereas it usually lasts for more than two months. Sow some Asparagus seeds in lines 18 inches apart in the open ground, or in rows between Moss Roses, small fruit bushes, or in any convenient place not too much in the shade. The end of April will be quite early enough for transplanting last year's seedlings; a good plan is to sow a field of Radishes in 1-foot wide beds, with 1-foot wide alleys between them, and to plant the Asparagus roots in the alleys. Beet-root is also a good crop to sow on the beds instead of Radishes. Asparagus ridges should now be earthed up as speedily as possible, an operation about three weeks later this season than it was last year. Radishes, according to demand and ground at convenience, should be sown either on unprotected beds or with the usual covering of litter. Radishes were plentiful this time last year, whereas the earliest crop this year will take a short time yet before it is fit for use. Sow some French Beans in rows in frames; steeping the seeds some hours previously to committing them to the soil greatly assists their early vegetation. Sow Parsley along with Radishes on beds, so that when the Radishes are removed the Parsley may occupy the ground. Sow some Seakale seeds, if seedlings are preferred to root cuttings; but for general purposes the latter are the best, for they produce good plants in one year, whereas seedlings require starving the first year and growing the second, thus occupying a period of two years. Seedlings of Seakale may be grown into large plants the first year, but their tendency to "run" when so treated renders it necessary to starve them by sowing thickly and allowing them to remain in that state during the first year. Transplant Lettuces on every available space, and sow some seeds of the white Paris Cos. Sow large patches of round Spinach, remove for market what is usable of the winter crop, and turn up the ground for Beet or Carrots. For these root crops deeply-trenched ground is best, and, if already rich enough, do not manure it at present, for manure is apt to produce forked roots. Onions may still be transplanted, and any Potatoes yet unplanted should be committed to the ground at once. Thoroughly clean the surface of Mint beds, and strew some soil from the intervening alleys over them. Mint forcing may be discontinued, for a supply can now be obtained from the open ground; the roots used in forcing, however, may be transplanted in some

damp, shady portion of the ground, and in two years they will have quite recruited their vigour. Cucumber growing must now receive attention. Pits which ought to be 5 feet wide and 3 feet deep should be dug out for them and filled with litter; the frames and soil should be got ready, and the plants transplanted when the heat has acquired the proper temperature.

## THE HOUSEHOLD.

### OKRA.

(*HIBISCUS ESCULENTUS*.)

THIS WEST Indian annual is grown for the sake of its pods, which in a green state may be used in soups or boiled and served like Asparagus; it is considered very delicious, and should certainly be more generally tried in England. The ripe seeds have been used as a substitute for coffee. It may be raised on heat in February or March, and planted out in June, or sown out of doors in May, in a warm sheltered spot; thin or plant out to 9 inches apart, keep clear of weeds, and earth up a little to support the stems; the pods should be gathered while quite young and tender. Messrs. Hooper, of Covent Garden, to whom we are indebted for so many rare and novel plants, figure it in their catalogue. So far as we have observed, the plant rarely comes to perfection in our houses, and the climate is probably too cool for its development

*Hibiscus esculentus*.

out-of-doors, though in Sussex, where the Capsicum is sometimes ripened on warm borders, the Okra might succeed. In gardens in the United States this is a common vegetable, and is by many greatly esteemed. H. R.

**Button-Hole Bouquets.**—Few seem to understand the difference between a button-hole flower and a button-hole bouquet, yet it is very great. The button-hole flower should be, as the word signifies, a flower, meaning a single one; whereas a bouquet means a number of flowers arranged together according to taste. Having, I hope, explained clearly the difference between the two, I shall endeavour to point out what constitutes a nice arrangement for button-holes. Flowers selected for mounting singly should be very choice; in fact, whatever flower is chosen should be a specimen in itself. One of our prettiest coat flowers is a white or pink Moss Rose; this I like to see with merely a leaf belonging to itself behind, and not Ferns, as one constantly sees in florists' shops. Ferns, to my mind, are better suited for Orchids, Gardenias, &c., than for Roses. An Orchid nicely arranged in the centre of a frond of maidenhair looks well, the delicate Fern setting off the Orchid to perfection; in short Ferns of this class are better suited to go with indoor than with outdoor flowers. Bouquets generally consist of three or more different kinds of whatever flowers may be in season, and a little Fern mixed through them. A little bouquet before me is composed of a half open white Camellia-bud, sprays of Lily of the Valley, and a few pips of a white Hyacinth, with a little Fern mixed through the whole. A great fault too often seen in button-hole bouquets is their large size and the way in which the flowers seemed packed, as it were, together; a few common hardy ones, if lightly placed, look often far better than tender flowers badly arranged.—A. H., *Upper Norwood*.

## NOTES OF THE WEEK.

— At the Special General Meeting of the Royal Horticultural Society, held at South Kensington on Wednesday last, the new bye-laws, framed chiefly for the purpose of enabling the Council to resign in a body, were confirmed by a large majority. The present members of Council will therefore now only hold office until a new Council has been elected; and we learn that it is proposed to hold a special meeting for that purpose, on Friday the 4th of April. This decision was arrived at after a stormy and excited meeting, which lasted nearly three hours.

— ASPARAGUS was cut last year in the London market gardens in the last week in March; this season it is not expected to be fit for cutting before the beginning of May. Of March Radishes, too, we have none; indeed, April will be well advanced before the first outdoor crop is ready for use. Winter Spinach has been, in many places, a partial failure, and that sown this spring has as yet made small progress. The season, in short, may be said to be from three weeks to a month later this year than usual.

— A BATCH of Clematises was shown the other day by Mr. Noble, of Sunningdale, in such a lovely condition as to fully prove their value for association with the most valued of early blooming plants for the greenhouse and conservatory. They were grown in a greenhouse temperature, and have been in flower since the middle of March.

— SULPHURET of calcium dug in around the roots of Vines is considered to have a powerful effect in destroying Phylloxera. This gives rise to a true sulphuric acid, in consequence of the moisture of the soil and the gentle disengagement of carbonic acid. It serves also equally well to destroy caterpillars and other injurious insects which are frequently so difficult to remove from vegetation.

— It is stated that Mr. Richard Smith, of Worcester, has presented, through Dr. Hooker, to the Chief Commissioner of her Majesty's Works, a valuable collection of species and varieties of Oaks, for the Arboretum of the Royal Gardens. The opinion expressed at Kew as to this collection is that, when arranged and planted, there will be no finer collection of such things in this country.

— A BOSTONIAN of magnificent possibilities wishes to organise a company with 12,000,000 dollars capital, to inclose a tract of several square miles in an immense glass structure, within which invalids may make their permanent abode, having a tropical climate, with its appropriate fruits and foliage, good hotels, picturesque drives, art galleries, an opera house—and, in short, everything that people in ill-health could possibly wish for.

— THE competition for the best design for laying out the new park at Lowestoft has resulted in the first prize being awarded to Mr. W. Clement Williams, of Halifax, and the second to Mr. George W. Usill, C.E., and Mr. J. W. Peggs, C.E., Westminster. The number of designs sent in was twenty-seven.

— STATISTICS, pitiless as ever, inform us that 5,825,000 bouquets is the average sale of the Bonapartist Violet in Paris, amounting altogether to about £21,000.

— THE very fine *Ficaria grandiflora*, a plant very much resembling, but much larger than our well-known Lesser Celandine, was shown in fine condition at Regent's Park on last Wednesday. It is a native of France, perfectly hardy, has been in flower since February, and will no doubt become a popular border plant.

— We have received from Messrs. Watts, of Northampton, some specimens of their white sprouting Broccoli, which, on being cooked, proved excellent. Not only the principal heads but the sprouts and even the young leaves that surround them are tender and well flavoured. Among sprouting Broccolies this must occupy a prominent place.

— We have just received the schedule of prizes for the Great International Exhibition, to be held in the Alexandra Park, on the occasion of its being opened to the public on May 21st. There are seventy classes for flowering and ornamental stove, greenhouse, and hardy plants, some of which are open to all exhibitors, others to nurserymen only. In these classes the prizes offered are on an unusually liberal scale, the first for sixteen distinct stove and greenhouse plants in flower for amateurs is £30, the second £20, and the third £10; other prizes range from £20 to £2 for firsts, and from £10 to £1 for thirds. Eighteen classes are devoted to fruits, the first prizes in which range from £6 to £1. A space of ground is set apart for the exhibition of horticultural buildings and garden requisites, for which certificates and prizes will be awarded according to the discretion of the judges. A portion of the terraces will be set apart for trials of lawn mowers, for which £10 are to be awarded for the best horse machine and £5 for the best hand one. On the 31st of May and following days an exhibition of plants arranged for effect will be held in the Palace, for which £225 will be given in

prizes; viz., to a group of one hundred plants, first prize £130, second £60, third £35. Intending exhibitors will be supplied with printed forms on application to Mr. Mackenzie, Alexandra Park, Muswell Hill, and which must be filled up and returned not later than the 17th of May.

— It may be interesting to our readers to learn that woods and plantations occupy in England 1,325,675 acres, in Wales 126,823 acres, and in Scotland 731,190 acres, being about 1.28th of the total area of the United Kingdom.

— *PRIMULA PURPUREA*, a Himalayan Primrose, is just now coming into bloom at Heatherbank. The flowers are much larger than those of *P. denticulata*, and of a deeper and better colour. The plant is in peat on rock-work.

— THE estate of Hannabfield, near Dumfries, which in consequence of the failure of heirs lately fell to the Crown, has just been handed over by the Lords of the Treasury to that town, and among other things arising out of the gift is the maintenance of a portion of the estate as a public park. The property, which is believed to be worth £20,000, is beautifully situated about half a mile to the south of Dumfries, and includes a mansion house, ornamental grounds, and a large expanse of grazing land skirting the left bank of the River Nith.

— It is a curious fact (remarks the *Graphic*) that the Drapers' Company have for some years been indulging in the luxury of a garden within a stone's throw of the Bank of England, at a cost of at least £12,000 per annum. Such is, indeed, the necessary inference from the announcement that there are negotiations in progress for letting the garden in question for building purposes at something more than that rent. Of course, if this garden were an ornament to London, we should have nothing to do but to praise the drapers for their past munificence, and regret that circumstances have now compelled them to exchange flower-beds for bricks and mortar; but the drapers' garden has always been studiously shrouded from the public gaze, and probably few of the busy thousands who daily traverse Throgmorton Street have even suspected its existence.

— A CORRESPONDENT of the *Times* relates the following case in reference to the Small Birds Protection Act.—"I was in hopes (he says) that the Act would rid our suburban fields of bird-catchers. Judge of my surprise and annoyance, then, when I saw this morning in a field adjoining my house the same old familiar sight which has pained me so often—a bird-catcher fellow, with all his apparatus in full work. Thinking myself fully armed with authority to order him off, I went out and called to him to desist, reminding him of the new law. He refused to do so, and when I threatened to bring a policeman, he coolly replied, 'The Bobby ain't no use; I've got the hact of Parliament;' and he pulled a copy out of his pocket and flourished it at me, shouting at the same time, 'I'm a catchin' linnets and chaffinches, as isn't mentioned in the hact.' So I was obliged to retire discomfited, and the bird-destroyer remained master of the situation."

— THE new Park rules are as follows:—"No public address shall be delivered, except in the open part of the park which is bounded by the horse-ride running from the Marble Arch to Victoria Gate, and thence to the powder magazine, and by the carriage drive running from the powder magazine along the Serpentine to Hyde Park Corner, and thence to the Marble Arch; and no such address shall be delivered in any place where the assemblage of persons to hear the same may cause obstruction to the use of any road or walk by the public, or to the use of the park by the military or volunteers, or to the use of the park under any of the reservations contained in the Act; and no such obstruction shall be wilfully caused by any person forming part of any assemblage which may have met to hear any such address. No public address of an unlawful character, or for an unlawful purpose, may be delivered. No assembly of persons is permitted in the park unless conducted in a decent and orderly manner."

— THE correspondent of the *Globe*, who stated that the Shamrock as worn at present is not an ancient emblem in Ireland, is said to be wrong; but is reported to be quite right when he says that it is not the plant spoken of by early English writers as having been used as food in that country, after the devastation caused by the wars of the sixteenth century. He is also considered to be correct in his conjecture that the Wood Sorrel was the plant meant by them. The Irish name of the Wood Sorrel is *shamroy*, which, by persons imperfectly acquainted with the language, might easily be confounded with the name of the Shamrock, if they judged by the ear, more especially if they judged by the eye, as S and R have nearly the same form in the Irish alphabet. Clearly "Shamrock," or, to give it its true orthography, *seamarog* (*Trifolium minus*), could never have been used for Wood Sorrel, except through ignorance, as *seamar* is the generic name of all the species of *Trifolium*, and could never have been applied to a plant so utterly different as *Oxalis acetosella*.

## SOCIETIES, EXHIBITIONS, &amp;c.

## CRYSTAL PALACE.

(MARCH 22 TO APRIL 5).

A GRAND exhibition of Hyacinths, Tulips, Narcissi, Crocuses, and other spring flowers—wholly supplied by Messrs. Downie, Laird, and Laing—now occupies the central transept of the Palace. Two long stages are devoted to these and other early-blooming plants, the whole being tastefully intermixed with Palms, Dracenas, and similar plants remarkable for the beauty of their foliage. Associated with these are also well-flowered Camellias and Azaleas, double-blossomed Chinese Peaches, Callas (with immense white, trumpet-like flowers), *Dielytra spectabilis*, Lily of the Valley, Mignonette, Pelargoniums, Spiræas, Chinese Primulas, &c. These are set, as it were, in an interesting frame-work of the graceful-looking bright-green *Isolepis gracilis*. The Hyacinths, which are numerous, are in admirable condition, their flower-heads being large and fine, and the colours rich and distinct. Amongst the dark blues, General Havelock still stands in the foremost rank, and King of the Blacks continues to be one of the best in its class. The fine azure-blue of *Connonne de Celle* will always render it a favourite; and, amongst red-flowered kinds, Macaulay occupies a prominent position. White flowers, always favourites with bouquet-makers, include Mont Blanc and Queen of the Netherlands, both fine kinds; whilst bright yellow is supplied by Ida. Of Tulips, Narcissi, and similar plants, there are also choice collections. Crocuses, too, shown in 1 and 6-inch pots, are smothered with flowers. Amongst the different subjects is likewise a large and interesting collection of one-year-old Cyclamens, variously coloured, the flowers having large, broad, blunt, and regularly-curved petals, whilst the foliage is vigorous and beautifully variegated. Altogether the exhibition is a very fine one in its way, and well worth inspection.

## ROYAL BOTANIC SOCIETY.

(MARCH 26TH.)

FINE as the first spring shows held in the gardens of this Society usually are, none of them that we have seen equalled that which took place there on Wednesday last. Both sides of the new glass corridor connecting the entrance gate with the conservatory were lined with plants of the most lovely description, and many of them had even to be accommodated in the Conservatory itself. The weather, too, was delightful, the full sunshine setting off the brilliant colours of the flowers to advantage.

**Stove and Greenhouse Plants.**—For a dozen of these in flower in 12-inch pots, Mr. Ward of Leyton, and Mr. G. Wheeler, Regent's Park, competed, the former being first with some well-flowered Indian Azaleas, a good plant of *Cytisus racemosus elegans*, fine plants of *Erica mutabilis*, *E. vernix coccinea*, and *E. Macnabiana*; a graceful little plant of *Boronia pinnata*, a well-bloomed specimen of *Eriostemon intermedium*, a plant of *Franciscæa calycina* with unusually robust foliage and large showy flowers, and fine specimens of *Lycaste Skinneri*, *Dendrobium nobile*, and *Odontoglossum cristatum*. From Mr. G. Wheeler and Messrs. Lane came hardy forced shrubs, consisting of Lilacs, Rhododendrons, Azalea *sinensis* and *pontica*, Guelder Roses, Andromedas, Prunuses, Spiræas, &c. Some well-flowered greenhouse Azaleas were exhibited in 12-inch pots by Mr. Ward and Mr. Wheeler.

**Chinese Primulas.**—For these there was a keen competition, and some groups were also shown for exhibition only. Messrs. Dobson & Sons had a fine collection, as had likewise Mr. James, of Isleworth, who showed some excellent plants of Princess Louise and Marquis of Lorne, the first a white and the second a red-flowered sort, both being improvements on the ordinary kinds. Mr. Little, of Twickenham, and Mr. Orsman, of Sutton, had also very fine groups.

**Specimen Cinerarias.**—Good groups of these were exhibited by Mr. James and Messrs. Dobson, who, in addition to those staged for competition, exhibited a miscellaneous collection of nicely-flowered plants. Amongst the finest were Lord Elgin, Orb of Day, Agrippa, Admiration, Formosa, and Snowflake.

**Lily of the Valley.**—Of this good examples were exhibited in pots, especially some from Mr. James, who was first with half a dozen superbly-grown plants, Mr. Reeves, of Acton, being second with another lot of well-flowered plants.

**Hyacinths.**—Those were altogether excellent; Messrs. Veitch & Sons staged a miscellaneous group of nearly eleven dozen of wonderfully fine plants. The same firm also gained the first prize for twelve sorts, with superb plants: the second prize group, belonging to Messrs. Cutbush, of Highgate, was likewise excellent. In the winning classes, *L'Innocence*, pure white, was very fine, as were also Prince Albert, an almost black kind, Von Schiller, Lord Byron, light blue,

and gigantea. Mr. Douglas, of Loxford Hall, obtained the first prize in the amateurs' class; the second being won by Mr. Weir, The Elms, Hampstead; and the third by Mr. Withall, Addison Road, Kensington. *La Grandesse*, white; Prince of Wales, blue; and *Koh-i-noor*, red, were amongst the finest in this section.

**Tulips.**—Of these several groups were shown, all in wonderfully fine condition; indeed a better dozen than that exhibited by Messrs. Veitch could not well be found; those from Messrs. Cutbush, too, which gained the second prize, were also very fine. In the amateur class, Mr. Douglas, Mr. Rowe, and Mr. Weir were the successful competitors, each furnishing excellent exhibitions.

**Cyclamens.**—Those from Mr. Little's garden at Cambridge Park, Twickenham, and from Mr. James, of Isleworth, were extremely fine, some specimens having considerably over a hundred expanded flowers on them, all in the greatest possible perfection. Mr. Little had also a large miscellaneous collection of this charming spring flower; from Mr. James came a year-old specimen called Miss Innes, the flowers of which were white and violet, the individual petals about three-fourths of an inch in breadth, regularly recurved, and very blunt, altogether one of the finest Cyclamens in cultivation.

**Hardy Flowering Plants.**—Of these Mr. Ware exhibited a large and interesting collection in pots: amongst them were *Iris persica* and *stylosa*; *Primula nivalis* with masses of white flowers, *P. elatior*, *acaulis*, *vulgaris auriculiflora*, very fine, *altaica*, *cortusoides*, the yellow-flowered *verticillata*, *erosa*, and *denticulata*; blue and white varieties of *Muscari botryoides*; *Scilla bifolia alba*, *S. sibirica*, and *S. Ughii*, bearing a large number of showy blue flowers; *Triteleia uniflora*, *Linum flavum*, *Sisyrinchium grandiflorum*, *Lachenalia*, Dog's-tooth Violets, Crown Imperials, *Tulipa Clusiana*, *Narcissus Bulbocodium*, *Funkias*, and others. *Dianthus barbatus atropurpureus*, with large, dark, copper-coloured foliage so suitable for spring gardening, also came from Mr. Ware, as did likewise a plant of *Aponogeton distachyon* in flower in an inverted bell-glass. Of *Ficaria grandiflora*, with large, showy, yellow flowers and luxuriant foliage, a fine specimen was exhibited by Mr. Parker, of Tooting.

**Miscellaneous Plants.**—A collection of Camellias in small pots was exhibited by Messrs. Lane, and another by Mr. Wm. Paul, of Waltham Cross, who also showed several boxes of very fine cut blooms of Roses; also a Hybrid Perpetual called Abbé Bramcrel, the flowers of which are very double and of a velvety dark-crimson colour. Mr. Paul showed, moreover, an extremely well-flowered group of *Lachenalia tricolor*. One of the most attractive features of the exhibition was a collection of Clematises in small pots, and profusely flowered, exhibited by Mr. Noble, of Sunningdale, all of which are well suited for early blooming and conservatory purposes, viz., Queen Guinevere, Lord Londesborough, Lady Londesborough, Lord Napier, Miss Bateman, and Albert Victor. A fine miscellaneous collection of plants was contributed by Mr. Williams, of Upper Holloway, which consisted of Palms, Ferns, Camellias, a specimen of *Inantophyllum minutum* with eleven immense trusses of flowers, and other stove and greenhouse plants. From Mr. Wheeler came also a somewhat similar group. An *Amaryllis* named Thomas Bundy was sent by the Rev. J. Readon, Southampton. One of the most attractive features of the exhibition was a dozen and a half of specimen plants of Mignonette furnished by Messrs. Rollisson & Sons, of Tooting, the plants measuring 2½ feet in diameter and the same in height. From Messrs. Veitch & Sons came a group of new plants that have not previously received certificates from this Society. Amongst them were *Maranta Makoyana*, *Dracena imperialis*, *Asplenium longissimum*, some Orchids, and a few other plants.

## COVENT GARDEN MARKET.

MARCH 28TH.

PRICES of Grapes range very high indeed, as do also those of forced Strawberries, Asparagus, and Green Peas. Of Easter Beurré Pears a fresh consignment has arrived from San Francisco, and large shipments of Apples from the United States.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Chestnuts, per bushel, 12s. to 20s.; Colts, per lb., 2s. to 2s. 6d.; Grapes, hothouse, per lb., 15s. to 35s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 4s. to 10s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 6s. to 10s.; Strawberries, per oz., 1s. to 2s.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 5s. to 10s.; French, 15s. to 30s.; Beans, Kidney, per 100, 2s. to 3s.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, 6d.; Cauliflower, per doz., 3s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 1s. 6d. to 3s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz., 1s. to 2s.; Mushrooms, per pottle, 2s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 3s. to 6s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 4s.; Parsnips, per doz., 3d. to 1s.; Peas, per quart, 5s. to 8s.; Potatoes, per bushel, 4s. to 7s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsify, doz., 1s. to 1s. 6d.; Savoy, per doz., 2s. to 3s.; Scorzonora, per bundle, 1s.; Seakale, per basket, 1s. to 2s.; Shallots, per lb., 3d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, per bunch, 3d. to 6d.

# THE GARDEN.

“This is an art

Which does mend nature : change it rather : but  
THE ART ITSELF IS NATURE.”—*Shakespeare.*

## SPRING FLOWERS.

THESE have seldom been later or more welcome than they are this season. Not that the winter has been severe, but it has been wet and dull, and the sun, rather than a genial atmosphere, is the great opener of the eyes of the sleeping flowers, arousing millions of all colours to greet him. Again, a few sharp frosts do not keep back flowers so much as a series of slight freezings. The latter seem to vex and fret plants almost beyond endurance. Violets have suffered severely this spring, and in most parts of the country their flowers have been exceptionally scarce. That grand bold-stemmed Violet, the Czar, seems to have lost in hardness what it has gained in length of stem and size of flowers, for I have had my blooms of it blackened again and again this year by frost, which has bitten deeper than usual on account of the earth being unusually moist. *Aubrietias*, *Arabis*, and *Myosotis dissitiflora* have also suffered much, the opening flowers having been repeatedly checked or nipped. I find, too, that the larger the patches the more, as a rule, the plants suffer, a circumstance for which I account in this way. The thick spread of leaves and branchlets entangles the rain and dew, and frost in consequence holds sway the longer; perhaps even till a gleam of sunlight hits them in a frozen state. Be that as it may, a safe rule in early spring gardening is, Small plants and many of them, if massive beds or rows are to be fully furnished without blanks. *Hepaticas* again, those brightest of spring flowers, are in many instances scant of bloom; and rabbits have delighted to make sport on their crowns full of flowers or otherwise. *Alyssum saxatile* looks in many cases rusty, as if the wet had pierced its floral heart, and left its trail-marks on its disfigured leaves. Primroses, on the contrary, seem to have enjoyed the dull rainy winter, and their charming heads of many-coloured flowers, resting on ample cushions of leaves, now form one of the chief features of our spring gardens. That bright blue-flowered plant, with which we are all so well acquainted, viz., *Omphalodes verna*, is also now in great beauty, and the flower-buds of the common *Gentian* are ready to burst with bloom. Snowdrops have been unusually fine and long-lived this year, the crimson one almost rising to the dignity of a tiny Lily in stature and size. The old single Snowdrop, however, still holds its place among our spring favourites. *Crocuses*, too, have been gay and fine, and *Tulips*, *Hyacinths*, *Narcissus*, *Squills*, *Anemones*, and *Lilies* are hastening on to carry the flush of spring beauty into the middle of summer. Some of these, such as *Squills*, some *Narcissi*, *Anemone apennina*, and others are already in flower, and the glorious old golden *Daffodil* is crowning in many a nook and corner the tender spring grass with a coronet of glory and proudly holding its own on spring bed or border, while in certain retired spots a far-reaching sea of golden heads is keeping time to the gentle breezes which we occasionally experience on these sunny April mornings. *Daisies*, red and white, are linked together in all sorts of combinations and quantities, calling up home memories, and cheering us up with hopeful gladness, as do also *Polyanthuses*, *Auriculas*, *Heartsease*, and *Forget-me-Not*, all of which help so much to sweeten and beautify the spring border or garden. F. T.

## GROUPING EARLY FLOWERING TREES AND SHRUBS.

It is not a little singular that the passion for grouping that has characterised late years has almost wholly expended itself on half hardy flowers. It is but seldom that one meets with a tastefully grouped bed, garden, or border of hardy flowering plants, while groups of flowering trees and shrubs are still more rare. Many of the latter, however, would obviously gain much by being massed. The faults of most of our ornamental

plantations and shrubberies are meagreness and monotony. The dotting style is largely responsible for the first; perpetual mixtures for the second. Massing is the way to breadth, richness, and intensity. One tree or shrub may be beautiful; three, six, twelve multiply the beauty, probably far beyond the ratio of the mere increase of numbers, as compound interest in the purse. The masses bulk out, fill the eye, and satisfy the mind. Each tree helps and is helped by its neighbour, many times over. We rest and are satisfied by a certain type, colour, or form of beauty, and then pass on with new zest to others. The key to the secret that one garden refreshes and pleases, while another, of much smaller size, becomes tiresome before one gets half round it, is, that the last is a featureless mixture, the other a changing panorama of beauty, unfolding new features at every step. There are several general methods of grouping trees and shrubs, such as the pure, all of one sort; the mixed, on either of the two opposite principles of congruity or contrast: the botanical, in families; geographical, in countries; statural, in equal or graduated heights and size, &c. But, perhaps, simultaneity of flowering would prove one of the most interesting and novel principles of grouping. Early in the season, however, we have, unfortunately, a very limited choice of showy subjects. In February, for instance, we can hardly be said to have more than one tree, the *Cornelian Cherry*, and one or two shrubs, such as the *Laurustinus*, the *Mezerion*, and a few early plants of *Berberis Bealii* and *Aquifolium*, with possibly *Rhododendron davuricum* and a few *Heaths*; and the whole of these, with the exception of the *Golden Cherry*, depend so much upon the season that they may not be in flower till March. We may also have the small catkins of some of the *Willows* and *Filberts*. But this *Cornelian Cherry* is a grand thing, either singly or in groups, especially if backed up by dark Scotch *Firs* or other *Pines*, or set in front of sombre masses of *Yew*. How the dark foliage throws out the golden flowers! Then again, what an eye or centre we have in this *Cherry* for a group of early flowering trees, which may alike give and receive richness of colouring and effect from its fading glory. Supported with double-flowering scarlet, pink, and white *Peaches* and *Almonds*, *Ribes sanguineum*, *Laurustinuses*, *Berberis*, *Daphne*, *Andromedas*, and early flowering *Heaths* and *Rhododendrons*, a group may be formed a picture of the very spirit of the spring. What richness, purity, and variety of colour—what contrast of character and form—what variations of height we have in these few plants! The *Heaths* lighting up the turf with their glowing brightness, and the *Peaches* and *Almonds* rising to the height of oreen surmounting the *Golden Cherry*, while *Ribes*, *Berberies*, &c., mingle their scarlet and gold with an easy grace that results in the perfection of art. True, among a redundancy of scarlet, white, pink, and gold, we lack blue to complete the colouring of the picture; but the missing link may be supplied in various ways. For instance, the base line may be filled in with the semi-glaucous variety of *Juniperus Sabina prostrata*, or the ground about the scarlet *Heaths* be cushioned with *Myosotis dissitiflora*, and the if possible yet more beautiful blue-flowered *Omphalodes verna*. Most of these trees and shrubs will flower in February or March, and even now, April 1st, the *Cornelian Cherry* is still arrayed in tarnished gold; while the *Ribes*, *Laurustinus*, and a few of the *Berberies*, *Daphnes*, *Heaths*, &c., are in full beauty. As the season advances we shall have more variety though hardly more beauty.

D. BURY.

IN 1810 (says the *Antiquary*) an Oak was felled near Newport, in Monmouthshire, measuring 28½ feet in circumference. It was supposed to be 400 years old, from the number of rings in the grain; and it was stated at the time that the timber sold for £670 and the bark for £200. The “Parliament Oak” in Clipstone Park is, according to tradition, one under which Edward I. held a parliament, and is supposed to be 1,500 years old. At Welbeck Abbey an Oak called “The Duke’s Walking-stick,” is 112 feet high. The “Green-dale Oak” covers a space of 700 square yards, and has a coach road cut through it. The “Two Porters” are 100 feet high; the “Seven Sisters” has seven stems 90 feet in height. There are some other extraordinary Oaks at Welbeck Abbey. The largest Oak in England is said to be at Calthorpe, in Yorkshire; it measures 78 feet in circumference where it meets the ground.

## NOTES OF THE WEEK.

— THE Missouri papers record an act of munificence on the part of Mr. Shaw, an English settler at St. Louis, which, though happily not rare in this country, is almost unexampled in the United States. It is the free gift of a noble park to the inhabitants of St. Louis. The tract set apart for this purpose is situated close to the town, is richly wooded, and abounds in picturesque scenery. It covers an area of over 300 acres, and its value is estimated at about £100,000.

— A LIST of Fellows, honorary, foreign, and corresponding Members of the Royal Horticultural Society, together with the Horticultural and Floral Societies in union with it, corrected up to the 1st of January this year, has just been published. To Fellows this list will be supplied on application to the Assistant Secretary for £2d., post free, and to the public in general for 1s. 1½d. We have also received a copy of the "New Charter, Agreements, and Supplemental Agreement" of this Society.

— THE pretty spring-flowering Crocus, commonly known as Crocus Aucheri, is finely figured in this month's number of the *Botanical Magazine*, under the name of "Crocus Olivieri." Dr. Hooker's account of the plant, which fully establishes the propriety of the latter designation, is as follows:—"Originally detected in the Island of Scio, in the Levant, by the French Oriental traveller and botanist, Olivier. . . . Subsequently it was collected at Guenive, in Asia Minor, by Ancher Eloi, and described from thence as a new species by Boissier (C. Aucheri)."

— THE following species of Bamboo are stated by M. E. A. Carrière to be "very hardy" about Paris, viz: *Bambusa viridi-glaucescens*, *violascens*, *aurea*, *mitis*, *nigra* (perhaps a shade less hardy than the rest), *Simenii*, and *Metake*. These are the most interesting species grown in the neighbourhood of Paris and are mentioned in the order of individual merit. M. Carrière adds that except in unusually severe winters even *B. aurea* and *B. nigra* do not suffer in the least from the cold there, and that all the kinds grow best, according to his experience, in a cool sandy-clay soil.

— WE learn that the gold medal of the first class, offered by the Belgian Cercle d'Arboriculture for the finest collection of trained fruit trees, has just been awarded by the jury of the Great Exhibition at Ghent to Messrs. Baltet, Brothers, nurserymen and fruit growers at Troyes. M. Chas. Baltet is favourably known in the horticultural world as one of the most experienced arboriculturists of the present day, and the author of "*L'Art de Greffer*"—the best treatise on grafting and budding that has yet appeared in any language.

— AN authorised English edition of the "*Art of Grafting*," by M. Charles Baltet, of Troyes, profusely illustrated, will be published at the GARDEN Office in a few days.

— ON Saturday last a public meeting of noblemen and gentlemen who feel an interest in the adornment of the metropolis was held in Willis's Rooms, to consider a memorial to the Prime Minister for the appointment of what may be called a permanent committee of good taste to advise with the First Commissioner of Works upon all metropolitan improvements, so that they may be carried out with a due regard to the canons of good taste. Lord Lyttelton occupied the chair, and there were also present the Duke of Sutherland, Lord Vernon, Lord Elcho, Right Hon. Mr. Cowper Temple, Mr. Beresford Hope, M.P., Mr. B. Cochrane, M.P., and others.

— WE learn that very energetic steps are now being taken at Paris to restore the flower market in the Cité, which was formerly known as the Quai aux Fleurs, being situated on the river side in that (the most ancient) part of the city. The new market will be established on almost the same ground, between the Tribunal of Commerce and the new Hôtel-Dieu. Like the old one, it will form three parts or divisions. The first, or *plateau*, which will be wholly devoted to plants in pots, and cut flowers, will occupy the space just mentioned. The second will be on the quay itself, behind the Hôtel-Dieu, and will extend from Notre Dame bridge to the bridge d'Arcole. Here deciduous and evergreen shrubs, Rose trees, climbing plants, vegetables, &c., will be exposed for sale. The third division will commence at the bridge d'Arcole and terminate at the bridge de la Morgue. The whole of this space will be occupied by the larger-sized fruit, forest, and ornamental trees. We are informed from the same source that, in addition to the above, three other new flower markets have been almost as good as decided upon—viz., one in the Place de Clichy, Batignolles; another in the Faubourg Saint-Antoine (probably in the Place des Vosges); and the third in the Place de Jussieu. These, with those already in existence, will raise the number of Parisian flower markets to seven. The others are—(1) the Grand Marché, in the Cité, open on Wednesdays and Saturdays; (2) the Madeleine, open on Tuesdays and Fridays; (3) the Château-d'Eau, open on Thursdays; (4) the market in the Place Saint-Sulpice, open

on Mondays and Thursdays; not to speak of the Marché Saint-Honoré, in which, in addition to a very large space devoted to cut flowers, bouquets, and plants in pots, much of the ground is occupied by a great variety of ornamental accessories for gardens and apartments, as well as of garden tools and utensils of every description. In reading the above, one cannot fail to be struck by the very forcible, and by no means flattering, contrast which London, so much superior to Paris in extent and in wealth, is still contented to present in the miserable accommodations afforded by its solitary recognised flower market in Covent Garden.

— THE Grass on the Thames Embankment has been attacked in a serious manner by the larvæ of the common daddy-long-legs, which seem to be unusually destructive this season. They will, however, soon be on the wing, when they will become food for birds.

— HERR ECKSTEIN, of Vienna, in an analysis of the comparative value of different disinfectants, concludes that chloride of lime is the cheapest and best, and advises that the substance be enclosed in a parchment bag, so that its effects may be slowly diffused through the polluted atmosphere.

— WE are glad to see that at length Tooting Beck Common, one of the finest of the open spaces within the metropolitan area, is to be added to those which are placed under the jurisdiction of the Metropolitan Board of Works, to be preserved for ever for the public use and enjoyment. It is reported to contain 144 acres, or thereabouts; one side of it lies contiguous to the common of Tooting Graveney, and there is to be no boundary fence between the two commons.

— MR. C. BACHHOFFNER, 4, Hatton Garden, has registered a mode of fixing flower glasses and vases to window sashes in such a way that the windows may be opened and shut without impediment. For conservatory use, or for affixing to shelves, stages, or similar projections, these brackets are equally applicable; they are furnished with clips and screws, which fasten them to whatever they may be attached, in the same way as pincushions may occasionally be seen fixed to the edges of work-tables.

— THE Tithe Commissioners in the Vicar of Gulval case have awarded that the sum of 1s. 6d. per acre shall be paid annually in respect of all lands now or hereafter to be cultivated as market gardens, and newly cultivated as such since the commutation of the tithes. This is below the lowest sum awarded in any other parish, which has varied from 6s. to 3s. 6d., per acre, and, therefore, the Vicar has determined to relinquish the award, not considering the amount to be sufficiently important to justify the trouble to receiver and payers of its collection.

— THE Queen paid her first visit to Victoria Park on Wednesday last, and was enthusiastically received.

— WE greatly regret to announce the death of the veteran and most amiable Nestor of American botanists, Dr. Torrey, of New York. He was superintendent of the Assay Office in Wall-street, and did a good deal of work besides botany. When in New York, in 1870, we were much indebted to him for kindly guidance and introductions, and had the pleasure of being present at one of his agreeable *réunions* of botanists and gardeners, which took place monthly in his rooms at Columbia College. American horticulture, as well as American botany, has benefited greatly by Dr. Torrey's labours. Torreya, a genus of Taxaceæ of North America and North-Eastern Asia, was named after him.

— THE great International Exhibition at Ghent has been, as might have been expected, in most respects quite a success, the grounds, which were tastefully laid out, being crowded with plants from nearly every country in Europe. In the class of twenty newly introduced plants in or out of bloom, the first prize was awarded to Messrs. Veitch, of Chelsea, who also received first and second prizes for the best new single plant in bloom, the first prize plant being *Tillandsia Zahnii*, a kind having pale green leaves beautifully striped with pink, canary coloured flowers and crimson bracts; the second being *Masdevalla Harryana*, a cool-house Orchid, to which allusion has often already been made in our columns. The handsome white-flowered deliciously scented *Toxicophlæa spectabilis* was also exhibited in this class by Mr. Williams, of the nurseries, Holloway, who showed, moreover, ten grand examples of *Ancetochilus*, for which he was deservedly awarded a gold medal. The same exhibitor also received a first prize for a magnificent collection of *Cyclamens*, which were the subjects of much admiration. For the best single plant not in flower, newly introduced into Europe, Messrs. Veitch were again first with *Dracæna amabilis*; and to the same firm was awarded the first prize for the best seedling Orchid obtained in Europe, the sort being the lovely *Cypripedium Dominianum*, a hybrid raised by Mr. Doniny between *C. Pearcei* and *C. caudatum*. Among others of our countrymen who were successful at this great continental trial of skill may be mentioned Mr. Maurice Young, who got a first prize for his Golden Juniper.

## THE ARBORETUM.

## HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE ROUND-LEAVED MAPLE (*ACER CIRCINNATUM*).

THIS forms a beautiful round-headed tree from 20 to 30 feet high, with contorted spreading branches and slender smooth shoots, frequently tinged with red. It comes from the Rocky Mountains, where it is said to be exclusively confined to the wooded portions that skirt the banks of the Columbia river. It is also found plentifully in Northern California, and was first introduced from that quarter by Douglas in 1826. Its leaves are orbicular, more or less cordate at the base, set on rather short footstalks, and are from seven to nine lobed, with the openings not deep, but very acute. They are smooth on both surfaces, sharply serrated on the edges, pale reddish-green when first they begin to expand, but afterwards, when fully developed, bright green, and just before they fall in the autumn they assume a brilliant crimson colour. The lobes are ovate-pointed, sharply toothed on the margins, and, except the lower ones, nearly all of one size, and with the nerves all

The Round-leaved Maple.

radiating from the top of the petiole to the tips of the lobes. In the flowers the sepals are purple, and the petals, which are white, are produced in terminal, nodding, stalked corymbs in April and May. The keys or fruit are smooth, bright red when young, purplish-brown when ripe, and have the carpels thick and oblong, and the wings widely extended. This Maple makes a nice small tree for planting singly on lawns. The length of a full-sized leaf is  $4\frac{1}{2}$  inches, including the footstalk, which is rather more than an inch long, and the breadth is  $3\frac{1}{2}$  inches.

## OSIERS.

I HAVE had an Osier ground for some years, and I find it to be profitable. The popular notion of an Osier bed is just any piece of land that won't grow anything else, where water stands all the winter, that you have only to dig over, push cuttings in, and take the crop off when the time comes round for that purpose. Osiers grown in this fashion will just cover expenses. To make them pay, the business must be well started, and the little that has to be done must be thoroughly done, and at the right time of the year. First shallow drain the land—say 18 inches or 2 feet, not deeper—with pipes; for Osiers live in dry, thrive in moist land, and die out in stagnant water. If you use hand labour instead of horse work in the draining, cut open drains and keep them clear; but, if possible, use horse work, as

it will make a considerable difference in the expense. Trench the land 12 inches deep, plant the cuttings 12 inches apart, and 18 inches row from row. Cuttings made of one-year shoots are the best. They should be cut about 10 or 12 inches long, and pushed into the ground the whole length. If planted too late (after the sap has begun to rise), the bark will peel up the cutting, and it will die. February is the planting month. For the first year keep the weeds under with a sharp hoe, and also keep rabbits down, unless you grow only the bitter kinds, which are not quite so profitable. Don't cut the crop later than February, and replace any cuttings that may have died. Osiers are sold as a standing crop, or in some places by weight or by the bunch. Whichever plan is adopted, let your own men cut the crop. The Osiers should be cut off close to the ground, or as nearly so as practicable. A bunch of Osiers is a number of rods tied together by two bands (made of Osier). The lowest band should be 12 inches from the butt end of the bunch, and should measure 36 inches in circumference; the other band is put round any distance up the bunch, and has no fixed length, being intended only to keep the bunch together. As soon as the crop is cut and weeds begin to appear, plough the land and harrow it; for, if the weeds once gain a good footing, it will make a large difference in the yield. About six or eight sorts are enough to grow, and about three-fourths of them should be kinds for peeling, which fetch a better price than those that will not peel. As soon as the shoots burst, use the hoe, or you may damage the plants. Any land, however poor, will grow some kinds of Osier; but the better the soil the better the kind that may be planted. Clay is hardly suitable for them, and sand is almost as bad. The value of an Osier rod depends upon its toughness and straight length. An acre of land will take about 28,000 cuttings. The cheapest way is to grow a small bed the first year for cuttings for the next. A well grown one-year-old rod will make three cuttings—not more, safely. Bought cuttings cost about 12s. the thousand. The shape of an Osier ground is material; it should be long and comparatively narrow, with vacant paths every now and then running quite through it, to enable rabbits to be shot as they pass over them. In a large square piece of ground it is almost impossible to get rabbits out. If pheasants are near, they are sure to go to an Osier ground—partly for cover, and also for insects, which they find in abundance in such places.—W. T. C.

**Catkins.**—During the last few months there has been a deceptive greenness diffused over the hedges in consequence of the numbers of Hazel catkins which, in this part of Surrey, they contain. We fancied weeks ago that spring was come or very near, but were deceived. Hazel catkins are very numerous this season, hanging all over the bushes; they are of a light yellow-green, and if examined closely, each "humb's tail," as it is sometimes called, will be found to be full of little bunches of yellow stamens, each bunch being protected by a green umbrella, as it were, from the wind and wet of February and March. Close beneath the hanging catkin grows the wonderful little nut-blossom. How small it is, yet how brilliant the crimson of the fertile flower on which the pollen of the stamens will drop and the Hazel-nut will grow! The catkins of the Willow, which we call Palm, are the most beautiful of all the catkin family. The stamens stand upright, and are of a brilliant golden colour; the fertile catkin grows on a separate bush, and is less pretty and interesting to look at than the other. I found the road strewn the other day under the Aspen Poplars with stout pink catkins. These were the barren flowers: the bunches of stamens were bright pink, shaded beneath little hairy hoods. This is the best time of year for observing the different kinds of catkins, borne by our half dozen native trees that produce them.—M. A. D.

## NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Cedars.**—Dr. Brandis states, in a paper read before the British Association for the Advancement of Science, that the Cedars of the Himalayas, of Lebanon, of Taurus and of Atlas, have all sprung from one original form, and are therefore but fixed varieties of one another.

**The Californian Laurel.** I can inform "W. F." (page 134) that *Tetranthera californica*, commonly called *Laurel regalis*, is perfectly hardy in this part of England, in fact more hardy than the Sweet Bay, *L. nobilis*. Here it forms a large shrub, and will soon be in bloom.—H. N. ELLACOMBE, *Bills Vineyard, Gloucestershire*.

**Churchyard Planting.**—I should be glad to learn what deciduous and evergreen shrubs and trees are best adapted for a much shaded churchyard in the heart of a smoky town. The idea is to produce an ornamental and garden-like appearance, and to do a little "holding out" in the summer months. The soil is rich and loamy, and the surrounding walls hideous.—A. CHURCHWARDEN, *Low Ashley*.

**Chamaecyparis Lawsoniana caerulea.**—This is a dwarf bushy plant, resembling *Beta compacta* in habit. It grows from 2½ to 3 feet high, the numerous and much sub-divided branches forming a broad spherical head, nearly 1½ foot across. The leaves are of a bluish or glaucous green, marked, especially on the under surface, with whitish or silvery grey bands. The appearance of this plant is of the most ornamental and pleasing description.

## THE FLOWER GARDEN.

### THE POLYANTHUS.

The Polyanthus is a charming spring-flowering plant, succeeding the Crocus and the Snowdrop, and forming a capital companion to that popular flower so closely related to it—the Primrose. It is perfectly hardy, but is somewhat impatient of cold and damp situations where there is a stagnant moisture in the soil; whilst, at the same time, it should not occupy too dry a spot, or it is in danger of being roasted up during a hot summer. During the past few years much has been done in the way of obtaining Polyanthuses that combine to some extent the rich and handsome lacing of gold that the old florists used to value so highly in the flowers with the robust constitution and sturdy habit of growth characteristic of the commonest border varieties. This is a great gain, and no one can look upon a clump of Polyanthuses with their handsome gilded flowers, without being struck with their rare beauty, and with a desire to cultivate them.

There are two ways of obtaining a stock of Polyanthuses—by division of the roots, and by raising plants from seeds. The seed can be sown in autumn or spring, or in fact at almost any season. My favourite plan is to sow in autumn in a shallow box or in pans, using some fine rich soil, and only just covering the seed with the same. If the box or pans be placed in a greenhouse, selecting a shady, cool part, or in a cool frame, the seed will grow readily, and by April of the following year they can be stood out under a shady wall, and should be kept well watered during the summer. By the first week in September the plants will be very strong, and if planted out in beds or on borders during moist weather, will make strong roots in the soil, and the following spring yield an abundance of flowers. It is of the first importance that strong plants be put out in order to secure a fine head of bloom. A bed of seedling Polyanthuses is always an object of considerable interest, and when grown in beds the mass of flowers thereby obtained enables one to appreciate their beauty more highly.

A deep yellow or black sandy loam, resting on a cool and moist subsoil, is the one to grow Polyanthuses in to perfection. Into such a soil they strike root deeply, and can withstand a long drought. On a heavy clay soil the Polyanthus does not flourish generally; the rootlets soon decay. The north or east side of a wall or fence, where the plants will get only the morning sun, is the aspect most favourable to their well-doing, and capable of prolonging to the utmost limit the beauty of the flowers. Where it is requisite, a compost should be formed in which to grow the plants; it should be compounded of good turfy loam, well-rotted cow-dung, so dry that it will readily crumble to pieces, and some leaf-mould, and laid on the bed to the depth of 9 inches. One great secret of success is undoubtedly deep planting. This is a principle that has always been insisted on by the most celebrated Polyanthus cultivators. The *modus operandi* of planting they observed was, in making the hole ready for the reception of the plant, to raise the soil up in the centre in the form of a cone, and then spread out the roots upon it, so that the plant itself should rest as it were upon the top of the cone. Then the foliage was gathered up, and the soil filled in around the roots up to quite one inch above the collar of the plant, *i. e.*, the point at which the leaves spring from the roots. During the growing season the Polyanthus throws out many young rootlets just below the surface of the soil, and the advantage derived from deep planting is that the best rootlets growing from the top part of the tap root derive more nourishment from the soil, and are more secure from drought in summer and frosts in winter. Frequent stirrings of the soil, top-dressing with fresh soil, and watering when required, are great helps towards the full development of the plants. When division of the roots is attempted, they should not be cut with a knife, but carefully torn asunder with the finger and thumb. According to the size of a plant will it divide into a number of plants, and each separate growth will be found to have roots attaching to it. When dividing, all old and decayed roots should be cut away. I strongly advise all fanciers of the Polyanthus to grow a few seedlings annually, as they make the strongest plants, and, when the seed is carefully selected, the quality of the flowers can be perpetuated as

certainly as in the case of divided plants. I am treating in this paper of the gold-laced varieties. In selecting flowers from which to obtain seeds, let size and regularity of the lacing of gold on the edges be regarded. Pin-eyed flowers, as they are termed—*i. e.*, those in which the pistil protrudes itself from the throat of the flower—should be rejected, unless possessing some distinctive quality worthy of preservation, as they look unsightly. R. D.

### NEW, RARE, OR NEGLECTED ALPINE PLANTS.

BY J. C. NIVEN, BOTANIC GARDENS, HULL.

(Continued from p. 214.)

*OROBUS HIRsutus* is a distinct and desirable dwarf species, growing about 9 inches high. It has somewhat broad leaflets of a light green colour, and lively blue and rose-coloured flowers. It grows freely.

*OROBUS LATHYROIDES*, though too tall in growth for association with the more truly alpine plants, is a lovely border plant. Its height, when growing vigorously, is from 18 inches to 2 feet; its flowers bright blue, produced in dense racemes, and its general habit all that can be desired; it is increased freely by seeds, which it produces abundantly. We have received it from continental gardens under the name of *Vicia nijniga*.

*OURISIA COCCINEA*.—A dwarf Scrophulariaceous plant, producing racemes of crimson flowers. Is a plant of recent introduction, and has a good habit, though, as we have found it, somewhat shy in blooming. A native of the Andes.

*OXALIS LASIANDRA* is nearly, if not altogether hardy, with long, narrow, deflexed leaflets, and the flower-stems rising 9 inches or 12 inches high; produces crimson flowers of considerable beauty.

*OXALIS LOBATA* is often grown under the synonym of *O. granulata*; it is well worth growing in pots for greenhouse decoration, as it produces its bright yellow flowers in November, a period of the year when such a colour, other than among the *Chrysanthemums*, is of rare occurrence.

*OROBUS VICIODES FLEXO* is a double form, a good deal like *O. vernus* in habit, but a more compact grower, and like all double flowers, retaining its beauty for a long period. Well worthy of cultivation.

*O. TAURICUS* and *AURANTIACUS*.—Nearly allied species; both have orange-coloured flowers, and require to be well established plants before they will bloom freely, and be seen in perfection.

*OXYTROPIS URALENSIS*.—A dwarf compact species from the Ural Mountains; its leaves are more or less white, owing to closely adpressed hairs; its flowers are produced in compact heads, rising about 4 inches high; they are of a rosy blue colour, and exceedingly attractive. No collection should be without this plant. Closely allied to it, and similar in size and growth, is a species I have grown for years, and provisionally named *Oxytropis cyanea*; the flowers are larger and of a lovely amethyst blue. My original plant has now been growing in a pot for fifteen years, and blooms freely every season; it is, however, very shy to increase otherwise than by seed, the production of which is very exceptional.

*PAPAVER SPICATUM*.—In the way of *P. pilosum*, but more woolly in the leaf, and more compact in growth, owing to the shorter peduncles; is well adapted for rockwork; its flowers are of an exceedingly delicate texture, and of a yellowish orange. The plant grows about 18 inches high.

*POLEMONIUM HUMILE* is a dwarf species, with small circular leaflets, and the whole plant covered with pubescence; the flowers are of a slaty blue, produced on short foot-stalks; the general appearance of the plant recommends itself for cultivation, more, perhaps, than the flowers themselves.

*PHLOX NIVALIS*.—A species now rarely met with in cultivation; much smaller in leaf and more rigid in habit than *Phlox subulata*; flowers are pure white; doubtless it and *subulata* constitute the origin of the pink-eyed *Phlox Nelsoni*; this origin appears to me to be well indicated by the shorter leaves and the white flowers—characters which it obtains from *P. nivalis*.

*PHLOX FRONDOSA*.—Belongs to the same section as *subulata* and *setacea*; but is a stronger and freer grower than either,

with larger flowers; admirably adapted for such a position as will enable it to trail its procumbent branches over the face of a mass of rock.

*PINGICUTLA LUTEA*.—With yellow blossoms; is a native of the Southern States of America, and ought to have a very sheltered corner; its association with the large blue *P. grandiflora* would have a very pretty effect, but it is rare in cultivation.

*POTENTILLA ARGENTEA*, as the name would imply, is covered over with silvery down; it is of a creeping habit, not exceeding 6 inches in height; and though scarcely definite enough in its argent character to give it a status in the gaudy ranks of the flower garden, it is yet a very desirable plant to place as a variety among dark-leaved plants in a rockery.

*PRIMULA AURICULATA* is closely allied to *P. farinosa* in outward appearance, but has larger flowers and, indeed, is altogether of a more vigorous habit.

*PRUNELLA GRANDIFLORA* var. *LACINATA* is a very distinct variety, producing, along with the large flowers of the parent species, leaves divided into linear lobes. It is considered by some to possess sufficient character to render it specifically distinct; but as I have observed a tendency in seedlings raised from it to revert to the normal type, I retain it as a variety, and a very distinct one, of *grandiflora*.

*PULMONARIA SIBIRICA* and *PULMONARIA ANGUSTIFOLIA* are both perfectly distinct species from *P. officinalis*. The former has the leaves beautifully mottled with white—so much so as to render it worthy of cultivation for its foliage only. The latter has narrow leaves, and both form dense crowns, from which the flowery branches arise in dense masses to a height of 9 to 12 inches.

*SAPONARIA CESPITOSA* is a far superior species to *S. ocymoides*, not so rambling in growth, but producing much larger flowers, of a warm rosy pink. It forms a thick, woody root-stock; and, when once fairly established, makes a permanent and valuable rock-plant. It likes a good strong soil, but free from damp.

*SAXIFRAGA LONGIFOLIA* var. *ELATION* was for years grown as the true type of *longifolia*. This form bears some resemblance to *ligulata*, but is perfectly distinct when in flower, the panicle rising to 2 and even 3 feet high, somewhat lax in the arrangement of the flowers, but the individual flowers are double the size of those of *S. ligulata*, and beautifully dotted with tiny crimson spots; a plant known as *Saxifraga nepalensis* is doubtless this old form of *longifolia* under a new name.

*SAXIFRAGA MUTATA*.—A yellow-flowered species bearing considerable similitude to *S. ligulata*; its flowery panicle is about 18 inches high, and I presume it is rarely seen in cultivation, owing to the fact that it not infrequently exhausts all its vigour in producing blooms, and rarely matures seeds in this country; further, it does not produce offsets, as most of this section do. It is a native of the Alps, but limited in its distribution.

*SAXIFRAGA PENTADACTYLIS* is the most rigid of all the mossy section, dwarf and compact in habit; it has a further peculiarity of exuding a gummy secretion, in the form of a white powder, that gives the plant (especially in spring) the appearance of frosted silver. In this respect it is allied to *S. ladanifera*, but in the latter the exudation is brown-coloured. It produces pure white flowers, and ought to find a place in every collection of this extensive genus.

*SCUTELLARIA MACRANTHA*, a native of Siberia, is the finest of all the species of this genus; it forms a hard woody root-stock, and is an excellent perennial alpine plant; it grows 9 inches high, producing an abundance of rich velvety dark blue flowers, much finer in colour than those of *S. japonica*.

(To be continued.)

### SMOTHERED FLOWERS.

We all insensibly speed the parting and welcome the coming guests rather too precipitately for the well-being of our plants. Look at bulbs to wit, how beautiful they are, and many of them fragrant as beautiful; but hardly have the flowers faded than we begin to be impatient with their leaves, the flower makers for another year. Hence they are either torn up and transplanted in full growth, tied into bunches out of the way like horses' tails at plough, or a huge

patch of *Nemophila*, *Virginia Stock*, or other early annual, is allowed to overrun and shut out every sunbeam with a thick, dense turf of beauty; and yet when the bulb resents this slight by coming forth weak or worthless the succeeding season, we affect to be greatly astonished, and talk or write about the *Crocus*, *Tulip*, *Anemone*, or *Gladiolus* disease. Disease indeed! We shut out the light, which is the life and vigour of the bulbs, that through the ministry of the leaves is manufactured into flowers, and then tell the poor blanched things to go on making their flowers all the same. It is in vain. The same is true of all spring flowers, with the difference of a simple word—for bulbs read crown. What the strength, size, and plumpness of the former is to next year's harvest of beauty, the same characteristics of crown are to the flowering of herbaceous plants the succeeding season. Overshadow these during the summer and autumn, and little or no golden glory of summer suns will light up your borders or gardens from February to May of 1874. You cannot reap two crops from the same sunlight and heat. These spring beauties have ravenous solar appetites; many of them never tire of basking and drinking in the sunshine. They seem merely idling or sleeping away the warm summer and autumn tide, and give no sign. They are busy, however, all the while. The more light, and air, and sun and free space they have, the more beautiful will they be when beauty is most wanted. All these are mere truisms, and it is humiliating to have to repeat them in various forms so often. Would that the repetition would arrest the evil, but it seems hardly to touch it. It is doubtful if a single mixed garden will pass through the summer without many choice spring and other herbaceous plants being crippled or ruined by the encroachments of grosser plants, either above or below, or both. But the greatest evils arise from the indiscriminate use of annuals. Their rapid growth and gross feeding bring ruin on choice Alpine or other plants. Each overshadowing leaf is a thief and a robber, weakening the stability of each crown for the succeeding season. To develop and strengthen these to the uttermost is the secret of success in the culture of all such plants as: early Violets, Primroses, Anbrietas, Daisies, Forget-me-nots, &c. Doubtless a reserve garden is the best situation for the preparation of all this future beauty; but it is not always available. The same spot must often be used to prepare and to display beauty; every plant is always doing one or the other; and space and a free out-of-sight skyward are equally or more essential for the preparation than for the exhibition. This is easily written, but in practice it is mostly ignored. The temptation is great to press upon plants unduly as soon as their beauty fades, and to give that huge patch of *Arabis* or *Alyssum* as much room as that glowing mass of *Clarkia* or *Godetia*. But if a difference is to be made, it ought to be in favour of the herbaceous plants. Thus only will the mixed garden bring forth perfect flowers in season all the year round. Whatever may happen under the bedding system, one of the chief charms of a mixed garden is a seasonable and continuous supply—not a glut of flowers during summer and autumn, a fallow in winter, and a skeleton yield of bulbs and other spring flowers. This is to fashion the garden on the model of extravagant households—a feast on Sunday, plenty on Monday, a fair supply on Tuesday, and semi-starvation for the rest of the week. In well-ordered households each day is provided for; so should it be in our mixed gardens. And to this end we must have zealous care of the leaves of bulbs and the crowns of herbaceous plants during the free growth of summer and autumn beauties.

T. D.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**New Zealand Flax.**—Can any of your readers inform me whether it would be (in a commercial point of view), worth while to cultivate *Phormium tenax* in those parts of the British Islands where it succeeds? I should also like to know whether the various sorts of *Phormium* offered by nurserymen are distinct natural species, or mere variations induced by cultivation.—W. F., *Isle of Man*.

**Propagating Roses.**—Two years ago I put in three rows of Rose cuttings of many varieties in October, and nine out of every ten made good plants the first year. I have this season three more rows, and on looking at them to-day (25th March) I find that they have all apparently taken well. During sharp weather I protected them by means of a little Fern.—G. R.

**Crocuses.**—I have plenty of yellow Crocuses; but shall be obliged by your giving me the names of half a dozen good kinds of other colours.—R. H. B. [The following will be found to answer your purpose viz., Dandy, blue, with white tips and purple base; King of the Blues, violet blue, very fine; Mont Blanc, pure white; La Maje-neuse, petals bluish, pale mauve, with a purple base, large and fine; Comtesse de Morny, large bluish with a purple base and striped; and Louis Philippe, bluish purple, very large and fine.]

**Spring-flowering Plants.**—The following are now in bloom in the Wellington nurseries, viz.: *Anemone blanda*, *Pulsatilla*, and *rannunculoides*; *Saxifraga coryphifolia*, *oppositifolia*, and its varieties *alba* and *pyrenaica*; *Primula dentifolia* and its variety *floribunda*, *erosa*, *glauca*, *helvetica* and its variety *alba*, *villosa*, and *Candahana*; *Scilla bifida* and *sibirica*; *Solihalla montana*; *Diondia Epipactis*; *Bulbocodium vernum*; *Cheiranthus præcox*; *Narcissus pinnatus*; and various *Hepaticas*, of which I think the single red is one of the most useful.—W. J.

## THE GARDEN IN THE HOUSE.

### COTTAGE WINDOW GARDENING.

WE find the following paragraph in the *Manchester Guardian* of Monday, March 24:

**COTTAGERS' FLOWER SHOW IN SALFORD.**—On New-year's Day we (*Guardian*) gave some account of a movement set on foot by Mr. Leo Grindon, Mr. John Edwards, and some other benevolent gentlemen whose names have not come to the front, for the encouragement of the growth of simple flowers in the windows and dwellings of the poor, so that objects of beauty might help to brighten them, and ideas of neatness and cleanliness be awakened and fostered, especially in the minds of children, to whom the care of the plants was to be specially entrusted. Several hundred Hyacinth bulbs were purchased, properly potted, and distributed gratuitously, but carefully, and chiefly in the immediate neighbourhood of Broughton-road, Salford, with the understanding that, when in bloom, there was to be a general exhibition. The show was held on Saturday afternoon, in the Richmond Lecture Hall, and showed the effort to have been far from in vain, not less than 250 plants being brought in by the owners—one a piece, of course—and of these at least 100 were such as would have done credit to any parlour. There was no doubt as to the kind of atmosphere in which each particular plant had grown—a fact that the Sanitary Association might do well to note; nor could there be any uncertainty as to the stimulus that had been given to notions of tidiness and pretty "get up," some of the flowers being trimly tied with ribbon, others labelled with tasteful little cards, &c. A considerable number of visitors paid their 2d. for admission, and in due time the prizes were distributed. These consisted of about a score of nicely-established Hydrangeas, Vallotas, &c., kindly given in person by Mr. R. S. Yates; while every exhibitor received a little packet of some kind of flower-seed suitable for the pot when the Hyacinth should be withered, with instructions how to sow it, &c. Lest there should be any difficulty as to proper soil, a gentleman resident in Lower Broughton expressed his willingness to supply every applicant. We take this movement, simple as it is, to be one of the kindest on behalf of the poor that the day has produced, and commend it heartily to the practical sympathy of all right-minded people. It is independent of sect or party, costs very little except personal labour, and lays the foundation for an immense amount of good results.

To the concluding sentences of this gratifying paragraph we say a most hearty "amen!" Just before Christmas last we ourselves reprinted, as our readers will remember, the card of "Instructions," a copy of which was given with every bulb, and invited attention at the same time to a movement which seems likely to progress so happily. While striving to ornament and improve our gardens and conservatories, time is well spent also in developing a taste for flowers among those who have never had the charms of nature presented to them in a way that could be understood, and especially who have never had a pot-flower to call their own. It is a duty, we take it, on the part of every man who is privileged to possess a garden, and who has felt the sweet influence of plants and flowers, to do the best that lies in his power to awaken the taste in others, and to gratify it. Nature knows no distinction of rich and poor; human hearts are constituted pretty much the same, whether the owners dwell in villas or in cottages, and if there be a ministry of good in the companionship of plants and flowers that affects the "upper class," it only wants proper and timely directing to affect the lower classes also, and to still greater advantage. The rich find stimulus in a score of beautiful things, such as the poor can never possibly possess, as costly books, pictures, statues, and other consummate works of art. In these the poor cannot even be made sharers, and so much the more reason accordingly is there why they should be encouraged to take interest in flowers, which, like the blue sky and the summer breezes, are independent of social distinctions, given for every one freely to enjoy. Those, we say, who are embosomed in surroundings wrought by art, and who can command what they please, in the way of Orchids and Camellias, are the people of all others to whom such a movement as this excellent one in Manchester should be interesting, for it is a compliment to their own taste that it should be imitated in a manner so amiable and inoffensive. Some one said, long ago, that the songs loved by the people were a capital index to their morals. It is certain that to diffuse the love of flowers would help to mend manners in many quarters that at present sadly need a change for the better; and we cannot but feel persuaded that the day will

yet arrive when, owing to the judicious promotion of cottage window gardening, it shall be said of the people, that what their songs were afortime, their flowers have become in the riper and better age. Simple and kindly endeavours to improve the complexion of the homes of the poor, and the dispositions and pastimes, especially of the children, appeal in the directest manner to their better feelings. For though often deplorably ignorant, working-men and their wives are not so dull as to be insensible to the leverage of kindly and unaffected endeavours to give them pleasure, and to brighten their existence, and that of their boys and girls, with something that needs no great intellectual effort; and it is precisely because so straightforward a matter as Hyacinth growing and attention to a Geranium or an Hydrangea can be accomplished by the weakest, that this particular department of window-gardening seems to us likely to prove so useful. From the paragraph above quoted, it appears that when the Hyacinths are over, there is to be an attempt in the way of flower-seed growing. This will require more care and attention, and for that very reason is again sure to be substantially useful, especially where there is pleasant and opening intelligence on the part of a lad or a girl, which wants only some engaging object to fasten upon. A flower some may consider a very poor thing to put in the place of a school-room lesson. So far from being an inefficient substitute, it is really and truly the best stepping-stone that can be provided when there is a genuine desire that the faculties shall be called forth. A book-lesson is often slurred because of its unattractiveness, whereas a flower holds the attention just because of its intrinsic and charming beauty; and directly that a youngster is got to take interest in the germination of his seeds, and in the evolution of stem and leaf and blossom, if he is ever going to think at all, then will be the time of his commencing. Think, too, of the habits of order, cleanliness, and tidiness which are induced by the endeavour to have good flowers! In its progress, the lad learns the blessedness of fresh air; the evils of dirt, and of invisible, but none the less noxious, vapours; the salubrity of sunshine, as a something not merely to play marbles in, but to utilize to glorious profit. A healthy and well-sustained interest in window and workshop flowers constitutes, in a word, one of the best assurances of eventual manliness and womanliness, and all who are wise and Christian will strive to promote it, especially in our large towns.

**Deciduous Azaleas as Indoor Plants.**—*A. calendulacea*, *glauca*, *viscosa*, *nudiflora*, *ponica*, and *mollis*, are all dwarf shrubs with deciduous leaves, suitable for indoor decoration. The first four are found in swamps in North America, and are the original stocks from which, by artificial fertilisation, the various garden varieties with deciduous leaves, small stems and branches, and white, rosy, and orange-red or sometimes even deep red flowers, have been raised. *A. pontica* is a native of the Caucasus and other Eastern ranges. It makes a more robust growth than the other kinds, and has pure yellow and very fragrant flowers. *A. mollis* is a Japanese kind, resembling *A. pontica*, and, like it, has yellow or reddish-yellow flowers. All these are equally well suited for forcing, and being low and much branched, with large handsome and fragrant flowers growing in umbels, they are amongst the best subjects that can be recommended for indoor decoration. For early forcing, only such specimens should be employed as have been grown in pots through the preceding summer, when they should have been treated like other shrubs, but should not be watered with liquid manure. They should not be pruned, and in autumn should be kept dry, to ripen the wood well, but not so dry as to cause any injury to their roots. After they have received a little frost, they should be placed in a cool room where the temperature is kept above freezing point. Specimens which it is desired should bloom at Christmas, should be removed into a warm room about five weeks before that time. If, before their removal to the warm room, they have stood for some time in a temperature of from 38° to 45° Fahr., the result will be much more satisfactory.

**Beaucarnea recurvata as a House Plant.**—I have tried many plants for the decoration of halls, porticos, and similar places, but this *Beaucarnea* has suited my purpose better than any of them, and in such positions has been universally admired. Well grown plants of it, about 18 inches or 2 feet in height, in eight-inch pots, make fine ornaments for this purpose, especially when placed in a vase and when the surface soil is covered with *Selaginella*. They are very retentive of life and will exist under house treatment unrequited for many weeks together.—JOHN FRASER, *York*.

## THE INDOOR GARDEN.

### DRACENAS.

TWELVE months ago I brought into the room where I am now writing a plant of *Dracena ferrea terminalis*, which, despite the gas-heated atmosphere, remained, with a weekly washing, in fine condition until the following April, and that in an atmosphere where dozens of flowering plants failed completely. But the best of the *Dracenas* is that they are not difficult of cultivation; with space and heat and moisture you may grow them to any size, and, with sufficient heat and cleanliness, you may maintain the plants in health after they are grown for many months. The plants are most easy of increase. Take an old stem—no matter how thick—cut it into pieces an inch long, lay these in congenial soil, give a bottom heat of 80° to 90°, and in three or four weeks each piece will be a sturdy young plant, which only requires time and care to grow it into a splendid specimen. No plants are more useful for table decoration than *Dracenas*, when suitable plants are selected. If they are too tall for that purpose, pass your knife round them at the desired height to the depth of the bark; with the thumb-nail press the severed part away; take a little nice sandy soil, and with a handful of Moss fasten it around the wound; and in a few weeks the head will be rooted, and may be removed with perfect safety to be placed in a vase or any other convenient place. Thus, to say the least of it, is a convenient way of extemporising a plant. Then every joint, from the place where the severance is made to the base, will produce a shoot that will make a plant; and, what is more, the stronger roots may be cut into lengths an inch or two long, and, under the same conditions as the stem cuttings, each piece will make a plant. There is therefore no reason why the *Dracenas* should not be cheap and common plants, for they may be propagated with the utmost facility, and, give them heat sufficient, they may be grown without much trouble. The plants procured, the next thing will be to grow them on; and for that purpose a temperature of 60° to 80° will be required, that is, 60° as a

minimum temperature, and 80° as a maximum. The plants are not particular about soil, but a compost of one-half turfy loam, one-quarter peat, and the remaining portion leaf-mould liberally intermixed with gritty sand and charcoal, will grow them to perfection. With a material of this kind, drain thoroughly and pot firmly, and if you can give the plants the assistance of bottom heat, so much the better. The plants do not grow in the young state very rapidly, but when the pots are full of roots a little warm liquid manure will assist them materially. As a rule the plants do not make more than a single stem the first season; but if cut down to near the surface

*Dracena terminalis.*

of the pot they may push two or three shoots, and these when cut again—we mean in the next year—six or nine. We have now a plant of *D. ferrea terminalis* with twelve leaders, each starting from within a few inches of the surface of the pot, and it is easy to perceive that such a plant will form, when fully developed, a mass of colour not readily to be surpassed. For house decoration nothing can exceed the *Dracenas*, so long as you keep them clean, that is, regularly washed; they seem to have a grasp of life under difficulties which few plants possess. So far we have spoken of the *Dracenas* as stove plants; but, as many of them come from New Zealand and Australia, they will of course succeed perfectly in the greenhouse, or even in the open air in the summer season. Of those remarkable for colour and good for winter decoration we should select *D. ferrea* and *D. ferrea terminalis* and *grandis*, both remarkable for the rich colouring of the terminal leaves. Then there is *D. Cooperi*, with highly-coloured and gracefully recurved leaves, one of the most beautiful of the family. Of more recent introductions may be named *D. Mooreana* (for an illustration of which we are indebted to Messrs. Veitch) and *Guilfoylei*, both remarkable for their rich tints of colour; while in *D. regia* and *Chelsoni* the crimson markings are replaced by white or cream-colour and white, and hence a group of *Dracenas* will be rich in variety as well as in colour. One secret in the successful management of the genus is that of regular washing both the upper and under side of the leaves. They are liable to be infested by

thrips and red spider, and washing with soap and water is the best preventive, and perhaps the best remedy. We may add that many of the *Dracenas* are admirable subjects for the sub-tropical garden, especially the more hardy kinds.

P.

### CRYSIS BRACTESCENS.

It is not a common occurrence to meet with a well-grown, healthy plant of this fine Orchid, or, indeed, with any species of the genus, so a few words on their culture may be interesting. This species is a native of Mexico, from whence it was introduced to this country in 1839. Its flowers are of a stout, wax-like consistence, white in colour, with a blotch of lemon yellow on the five-lobed crest. When well grown it produces spindle-shaped bulbs, from 1 to 2 feet in length, bearing five or six lanceolate leaves with undulating margins. Each young growth produces one or occasionally two spikes of flowers, which are closely arranged on the spike. This plant, together with its congeners *C. aurea*, *C. Limminghii* and *C. levis*, grows well in baskets suspended near the light. All the species grow well in living sphagnum and crocks, and require a humid atmosphere, together with an abundant supply of water at the root when growing. The syringe must be used freely, and care must be taken to keep the foliage free from the ravages of thrips, otherwise the plants will speedily become unsightly, producing weak spindling growths, that are extremely liable to damp off. *C. Limminghii* has smaller flowers than those of *C. bractescens*, and they are of a purplish lilac colour, the lips being streaked with crimson. Of this species there is a most remarkable specimen in the collection of Dr. Poppleton, Newley, near Leeds, with pseudo-bulbs 18 inches long, and as thick as one's wrist. This plant has borne from sixteen to eighteen fine spikes for several years in succession, and is worth travelling miles to see, since no description can do it justice. *C. undulata* is a rare and handsome species, the pseudo-bulbs of which are some 18 inches in length, and the flower-spike produces eight to ten blossoms, the sepals and petals of which are of a lovely orange yellow, the lip, which is cream-coloured, being striped with pink. Of this a fine plant exists in the Meadowbank collection. All the species are easily propagated by cutting off the back bulbs and laying them on their sides on living sphagnum, in a close propagating case. They will luxuriate in an intermediate house, but it must be very humid and moderately shaded from bright sunshine.

F. W. B.

**Marechal Niel Rose under Glass.**—What a glorious Rose this is when planted out in a rather cool house and allowed to develop itself! Two years ago I planted on a back wall, in a new house just erected, a plant I had bidden on a briar the previous summer. The situation was not particularly favourable for it, as it does better trained nearer the glass; but last year it made shoots, some 10 feet long, which were laid in along the wall their full length, and now every eye has broken, and the plant is studded with bloom buds over the whole surface. A stronger plant of climbing *Devoniensis*, planted at the same time, has not done near so well. One of the very best plants of *Marechal Niel* I ever saw was planted in an open-roofed orchard house (where the fruit trees were grown in pots), and it had rambed unpruned, or nearly so, all over the roof; but the foliage was not sufficiently dense in any part to injure the trees beneath, and in fact, I was told a much larger return in profit was derived from the *Marechal* than from the potted trees for which the house was originally built. There is an old tea-scented Rose called *Moiret*, a strong, vigorous grower, and one of the best to plant under glass I have ever seen. Some years ago I had it in a lofty conservatory, trained up one of the pillars, and allowed it to ramble about near the glass. We could at almost any time, either winter or summer, cut a beautiful bouquet of Roses from this old plant. In winter the flowers were almost a pure white, but as the days lengthened the edges of the petals were tipped with pink. I have a plant of it on a south wall here, but in the open air the colour is a beautiful lilac-tinted pink. I cannot imagine a greater luxury amongst flowers than a house devoted to *Tea Roses*. Planted in a good border, allowed to develop themselves, they then assume their true character, which is much unlike the long miserable plants of them which we sometimes meet with in pots; and when well treated and in vigorous health, that bane of their existence, mildew, is not nearly so troublesome as it is when the plants are grown under less favourable circumstances.

—E. H., in *Field*.

### BIGNONIAS.

THESE profuse blooming and extremely ornamental plants are popularly named Trumpet Flowers; they are climbers, furnished with numerous tendrils, by which they attach themselves to surrounding objects. Although the majority of Bignonias are natives of tropical countries, several kinds will live with us out-of-doors all the year round; others succeed in the greenhouse or conservatory, whilst some, and perhaps the largest number, require stove heat, where, if trained upon pillars or rafters, they form noble ornaments; in short, they may be reckoned amongst the most beautiful and gorgeous of climbing plants, when grown in the border and so trained; but they cannot be recommended as pot plants. The soil best suited for their growth is good loam two parts, peat one part, and a sufficient quantity of sand to make the mixture feel gritty. In planting in the conservatory border, spaces should be boxed off, in order to restrict the too great extension of the roots. Although Bignonias are not well suited for permanent pot culture, it will be necessary to grow them in pots for a year or two, before planting them out, in order to get them up a considerable height, or they may be some time before they recover from the change, and thus disappoint the expectations of the cultivator. They require ample drainage, an abundant supply of water during the summer season, and a limited amount in winter; but the drying off system must never be carried out severe enough to shrivel even the young wood. In early spring the plants may be pruned and the shoots thinned out, so that the sun may not be excluded too much from other plants which may be growing below them. During the growing season the syringe must be used frequently until the flowers begin to swell, when its use must be discontinued.

**B. venusta.**—This is a plant of robust growth, and one which must be allowed ample space; the leaflets are oblong-ovate and acuminate, the flowers large and trumpet-shaped, of a glowing orange-crimson colour, freely produced, and keep in full beauty for at least two months at a time. To grow this plant well it should be planted in the bed of a stove in bottom heat; but this treatment is by no means compulsory, as it thrives well in a warm greenhouse. It is a native of Brazil.

**B. speciosa.**—This species is less robust in growth than *venusta* and may be grown in the warm end of a conservatory. The foliage is oblong-ovate, and shining light green in colour, and the trumpet-shaped blooms are produced in abundance from the axils of the leaves. They are about 2 inches in diameter, of a soft lavender colour, shaded with violet and purple, and have a white throat. It is a very handsome plant, which may be found in some collections under the name of *B. picta*. It is a native of South America.

**B. Chamberlaynii.**—This superb species should find a place in every plant-stove, for although not quite equal to *B. venusta* in beauty of inflorescence, it is nevertheless a magnificent climber, and not being so robust as *B. venusta*, may be accommodated in a smaller stove. The leaflets are ovate-acuminate, usually produced in pairs—smooth, shining, and dark-green, and furnished with a strong tendril, by which the plant fastens itself securely to anything with which it comes in contact. The flowers, which are produced in drooping racemes from the axils of the leaves, are trumpet-shaped, the tube being upwards of 3 inches in length, whilst the five-lobed spreading limbs frequently measure 4 inches in diameter; they are of a soft bright yellow, and are produced in succession from May until October. It is a native of Brazil.

**B. jasminoides.**—This kind, which is called sometimes *Tecoma jasminoides*, is a native of Australia. Its leaves are pinnate, there being about two pairs of pinnae, besides the terminal one. These are oblong-lanceolate, with a somewhat obtuse point, smooth, shining, and dark green on the upper side, paler below; the flowers are large, funnel or trumpet-shaped, and bluish-white, with a purple stained throat. It blooms during July and August, and is a magnificent plant for the conservatory. There are several varieties of it to be met with, all of which are very beautiful.

**B. grandiflora.**—This is a splendid plant for the greenhouse, and in the warmer parts of England it succeeds admirably against a wall in the open air. Its leaves are pinnate, from 6 to 12 inches long; leaflets ovate-acuminate, and slightly toothed at the edges. The panicles of bloom are terminal and pendulous, much branched, often measuring 2 feet in diameter, whilst the individual flowers are trumpet shaped, some 4 inches in diameter, and rich tawny orange outside, the throat being bright orange. It flowers through the months of July and August, and is a native of China and Japan.

**B. radicans atro-purpurea.**—This differs from the normal form in having its blooms beautifully suffused with deep purple. A very desirable hardy plant.

**B. Cherere.**—This is a fine stove species, having angular stems,

and leaflets ovate-acuminate, smooth, and dark green. The racemes are terminal, and are ornamented with a profusion of large rich yellow trumpet-shaped flowers. It blooms during June and July, and is a native of Guiana.

**B. capreolata.**—This plant is well adapted for a greenhouse, where it will display its beauties from June to August; the leaves are pinnate, leaflets somewhat cordate, oblong, and furnished with three cleft tendrils; the racemes are axillary, bearing trumpet-shaped reddish-yellow flowers. It is a native of the southern portion of the United States.

**B. unguis.**—This species cannot be reckoned amongst the most showy kinds, yet it is sufficiently handsome to merit a place in any collection, whilst, being of less robust habit of growth than most kinds, it may be grown into a handsome specimen upon a balloon-shaped trellis. Its leaves are pinnate, leaflets ovate-acuminate,

*Bignonia radicans.*

tendrils strong and three-cleft; the flowers are produced from the axils of the leaves, and are of a bright rich yellow colour. It blooms freely during the months of June and July, and is a native of Caracas.

**B. radicans.**—A beautiful hardy species, well adapted for covering walls or old trunks of trees. Its leaves, as will be seen by the annexed illustration, are large and pinnate, and the flowers, which are funnel-shaped and of a rich orange-scarlet, are produced in July and August. It is a native of North America.—*Favos.*

**Gesnera elongata.**—Last December there were in the warm houses of the Museum at Paris some fine specimens of this *Gesnera* completely covered with brilliant scarlet flowers. This fine old plant seems to have become rather rare in France. It is one of the finest winter-blooming kinds, the flowers, although small, being very numerous and of the most exquisite deep scarlet colour, while the habit of the plant itself is very pleasing and elegant. It was originally discovered by Humboldt and Bonpland in Peru, not far from the city of Quito.

## VENTILATION.

The objects of ventilation are twofold—first, the lowering of the temperature of plant structures during the heat of the day; and, secondly, the constant renewal of the atmosphere of our plant-houses. In lowering the temperature we should be guided by the nature of the plants with which the house is stocked; thus a house containing Heaths, Epacrises, and similar hard-wooded plants from temperate climates will require free ventilation throughout the whole winter when the atmosphere is not frosty, while another house stocked with what are called stove-plants, or forcing Vines, will require to have the air admitted at the same season with the most extreme caution, and the danger to plants, as to the human subject, is a cold draught, especially when the atmosphere is frosty. We have frequently had plants severely cut opposite a broken square of glass, while others standing opposite an open sash have been quite uninjured. The great point, however, with what are called greenhouse plants, whether hard or soft-wooded, is to bring them up hardily, that is, as the days shorten and the natural heat decreases in the autumn, to get the plants firm-wooded and hardy, and with sufficient substance in them to resist the parching effects of cold winds, should they blow upon them. If you take a plant from a high temperature to a low one, that is from a temperature of sixty degrees to one of forty, and expose it to a free circulation of air, the leaves will in a short time become flaccid, and the younger ones quite dried up. But if you gradually inure the plant from the high to the low temperature, the tissue hardens, and the plant is able to resist the low temperature. Through a Heath-house the cold wind may whistle without injury to the plants, but the same air in passing through a collection of *Pelargoniums*, or *Cinerarias*, if it did not parch them up, the leaves would become comparatively withered, or what is termed foxy or red, around the edges. Hence the importance of suiting the winter arrangements of plants to the respective situations which they must occupy. Thus Heaths and Epacrises may stand opposite the ventilators, but the more tender New Holland plants, such as *Pimeleas*, *Leschenaultias*, *Gompholobiums*, *Chorozemas*, &c., require a comparatively sheltered situation where the wind will blow softly, and where, if possible, the temperature will be some degrees warmer than in other parts of the house. The advantages of the constant circulation and renewal of the atmosphere of plant structures are so great, that in erecting them arrangements should always be made to admit in cold weather a good volume of air near the heating apparatus, so that it may be warmed before it comes in contact with the plants; and were it not for the expense it would be well if a little extra fire heat could be used, so that there could be a constant circulation of fresh air by night and by day. Practically speaking, ventilation should commence at the top of the house first, the object being to let off any contaminated air that may have been engendered during the night. For this purpose a mere chink to two or three of the top ventilators or sashes early in the morning will be sufficient, and these openings must be increased as the temperature rises, until, if the external atmosphere is sufficiently mild, the front ventilators may be opened and a free circulation allowed throughout the house. This remark applies more especially to cool plant houses, but where forcing is going on a little more caution will be necessary. Air must still be admitted at the highest point early in the morning, and be increased as the temperature may require, but great caution must be exercised in opening the front ventilators, unless you have the power of warming the air before it comes in contact with the plants. If you have not this power, and the exigencies of cultivation demand front air, then the openings of the ventilators should be covered with woollen netting of a quarter-inch mesh, so that the cold air may not rush in in volume, but may be gently sifted and warmed as it passes into the house. Nor is this all: cold air being dry, requires to be moistened, and if this moisture is not provided by artificial means (such as evaporating troughs upon the heating apparatus, a fermenting bed of dung, leaves, or tan, or by sprinkling the floors, walls, and paths almost constantly with water, or better still, by fitting the house with the patent panelled and perforated water slabs), the air will draw its moisture from the foliage of the plants, and hence vigorous growth will be impossible. In a large forcing establishment it is generally the work of one or two men to sprinkle the houses—that is, from the opening of the ventilators in the morning until the closing of them in the afternoon, they go, watering-pot in hand, and sprinkle every bit of available space, so as to keep it moist, and the atmosphere of the house loaded with vapour. Indeed, what we want in our forcing-houses is just what nature supplies in tropical climates, or what we occasionally, but rarely experience in this country—that is, an atmosphere loaded with moisture, and yet warm—not hot—and genial. Then it is that plants grow with renewed vigour, and their growth goes on without the slightest hindrance—then it is that you get broad vigorous foliage and sturdy growth, and then it is that the plant lays up that store of nourishment which builds up its

fabric, and forms the flowers and fruit. But there is yet another phase in which ventilation must be considered. So far we have been thinking of growth, but maturation is necessary, and whether that consists in the formation of flowers, or the perfect ripening of fruit, the conditions necessary must be supplied. For growth, moisture is indispensable, but for maturation a drier atmosphere is necessary. Hence, when the growth is drawing to completion, or the fruit begins to change colour, then it is that atmospheric moisture must be gradually decreased, so that by the time the fruit is matured, the atmosphere may be much drier. To sum up—ventilate early in the morning and gradually increase the volume while the sun is full upon the house, but when it has passed the meridian and the rays fall obliquely, gradually decrease it, and finally close the house some time before the rays leave it. Avoid cold draughts. Keep up plenty of atmospheric moisture during the growing season, and you will not go far wrong. As we advocate a constant circulation of fresh air when it can be safely had, it is scarcely necessary to say we approve of night air, and to that end, and particularly during the ripening season, we admit a little air the last thing at night, and allow it to remain on all night.

W. P. AYRES.

## GARDEN DESTROYERS.

### VINE PESTS.

THESE, as a rule, come from neglect. Keep the atmosphere of your vinerias in a clean and healthy state, attend to the ventilation in a timely and proper manner, and you will not be troubled with either insects or mildew; but, neglect these precautions, and one, if not both, will quickly be seen upon your Vines. Red spider and thrips luxuriate in a dry close atmosphere, mildew in a close damp one; but it is a rare thing for either to appear if the atmosphere of the house be kept pure and healthy. A healthy atmosphere can only be secured by the timely admission of air in the morning; indeed, the atmosphere of a forcing or plant house, to be really healthy, should have a constant ingress and egress of fresh air night and day, not necessarily a strong draught, but just sufficient to admit of a gentle circulation of fresh air. All good cultivators are cognisant of the importance of an arrangement of this kind, and for very early forcing special arrangements are made to that end. The best and most durable arrangement for this purpose is to place opposite two or three of the ventilators (the number being governed by the size of the house) frames of the necessary width, and about 1 foot deep, filled in with fine perforated zinc. Through this the heated air escapes very gently, but still sufficiently to allow of the necessary change of air. An atmosphere so regulated, with a sufficient degree of moisture, is the very opposite of what is required for the propagation of mildew or insect life.

There are, however, some insects which, if they get upon the Vine, are special nuisances, and of these notably the mealy bug, and the mussel and brown scale. For the extermination of these pests, nothing short of a complete removal of the loose bark, thoroughly scrubbing the Vines afterwards with soft soap and hot water, and then painting them with a wash consisting of strong soapsuds, lime, soot, and sulphur, mixed to the consistence of thick paint, will suffice. For the first painting it is better to omit the soot, as, with the second coat, containing the soot upon the white foundation, you will be better able to see that the whole plant is thoroughly coated with the wash, more especially the cracks and crevices around the spurs. Upon this the success of the application mainly depends, and therefore too much care cannot be taken in applying the mixture. If, however, mealy bug has been allowed to establish itself in the house, nothing short of painting the house, carefully stopping every crevice, and lime-whiting the brickwork with hot lime will be sufficient to ensure a complete cure. Mealy bug is not generally a Vine-pest, but when it gets upon them, and more especially among the bunches of ripening fruit, it spreads with uncommon rapidity, and soon renders the Grapes unfit for use. The brown and the mussel scale yield to the same treatment, though the latter is more troublesome than the former, and to ensure the destruction of its eggs, the horny coating which covers it must be removed before applying the wash.

As to red spider, its ravages depend in some measure upon locality. Some places and houses can scarcely be kept free from it, except by the most painstaking attention; while others are rarely infested with it at all. Indeed, as has just been remarked, cleanliness is the great preventive of insect ravages, and therefore at the time of the winter pruning it is wise that the woodwork of the house should be thoroughly cleansed with soap and water (if not painted), and that the walls should be lime-whited, mixing with the lime-wash a fair proportion of sulphur. The best way to do this is to put several lumps of quick-lime into a bucket, and then, putting warm water to it, let it stand until it begins to boil; then add half a pound or more

of flowers of sulphur, stirring the two intimately together, and by the time the water ceases to boil, the lime and sulphur will have become united; when, if you pour off the clear liquor, you will have a solution of sulphur; and this, mixed in the proportion of one part to three of clean water, will destroy red spider instantly. This is a preferable application to that of dusting sulphur over the plants and houses, as is the usual custom; but it must be remarked this solution should not come in contact with the paint of the house, or it will combine with the white-lead, and form a black sulphide, imparting a very ugly appearance. One more precaution let me note, and to that particular attention must be paid. In making liquid sulphur, decant and stopper the bottles quite closely directly the liquid has settled. If corks are used, they should be sealed or resined down; when a bottle is opened, it should be used immediately. By the use of liquid sulphur the spider may be kept in check; but as it cannot be applied after the fruit is set, then the vapour of sulphur must be resorted to. This may be applied either by coating the hot-water pipes with sulphur mixed, to the consistence of paint, with skimmed milk, and then when the pipes are warm (but not hot) damping them for an hour or two on three successive evenings, so as to keep the house full of sulphur-impregnated vapour; or it may be used as follows:—Procure a bushel or so of lime quite fresh, and placing it in tubs in different parts of the house, pour hot water upon it. As soon as the lime begins to slake, throw into each tub half a pound of sulphur, and stir it well into the lime. Add more hot water if necessary, and the house will soon be densely filled with sulphur vapour. Two or three applications of this kind will be found a complete cure for both red spider and mildew.

Thrips must be dealt with either by fumigating with tobacco, or washing the plants with a weak decoction of tobacco water. The former is the only cleanly and efficient remedy; but the application must be repeated three times, say twice in the first week, with an interval of a day or two, and then again in about ten days. By this time the eggs from the first brood of insects will have hatched, and thus may be readily destroyed. Three fumigations within ten days or a fortnight I have invariably found to be a complete cure. Thrips, however, have a strong feeling for self-preservation, and no sooner do they scent anything wrong in the house than they drop from the plants and bury themselves in the soil; hence the advantage of a second smoking in the same week, to catch them when they have returned to the plants.

Of appliances for fumigating we have plenty; but the best, the cheapest, and the most effective is a wire basket, 1 foot or 18 inches square and 6 inches deep, with a strong wire from each corner to suspend it by. Into the bottom of this throw a handful of hot cinders, and over that another handful or two of charcoal. Then swing the basket about for a few minutes, and you will have a nice red fire. The best tobacco for fumigating is undoubtedly common shag, and, properly used, I believe it to be cheaper than most of the tobacco papers now offered to the public. In using this tobacco, I procure a handful or two of wet litter from the stable, and, chopping it into pieces about an inch long, mix it with the tobacco as intimately as possible. Then place it upon the fire, give the basket a swing or two in the air, and a volume of smoke will be evolved that will fill the house in a few seconds, and not only that, but, if the mixture is in a proper state of humidity, it will continue to burn for some time, and thus keep the house filled—a very important point in destroying thrips. Suspend the basket in the house, and the only further precaution necessary will be to watch and damp it should the tobacco burst into flame. By these simple means fumigating is reduced to a minimum of trouble; and to fill half a dozen houses with tobacco fumes in thirty to forty minutes is an easy task. A.

**Ash Plants Barked by Mice.**—I forward for your inspection two young Ash plants, about 8 feet high, cut this morning from one of our plantations. You will perceive that the bark has been gnawed away from the root to the upper twigs by some small rodent. I suspect the delinquent in this case to be the common field mouse. Nearly half the Ashes in a plantation eight acres in extent have been either quite destroyed or more or less injured by the little enemy in question; and, judging from the extent of the fresh injuries which we daily perceive, the evil is one which is not likely to cease. Can any of your readers suggest a remedy for this damage? I find that other plantations in this neighbourhood are similarly affected. In every case it is the Maiden Ash that is attacked, the shoots or suckers from the old stools being untouched. The field mouse, like the house mouse, has increased immensely during the late wet and unseasonable summer and autumn. The Grass in the pastures and on every dry bank is tunnelled in every direction with their runs, and they swarm alike in houses, buildings, and stacks along with the common mouse. Unfortunately, now that the hawks and owls have been exterminated, there is nothing left to keep these pests within

reasonable bounds.—J. C. [The mischief is certainly the work of a small rodent, and there is little doubt that our correspondent has decided correctly on the species, the long-tailed field mouse. As to the remedy, it is difficult to suggest one. Owls prey unceasingly on these mice by night, and kestrels by day; these invaluable birds, to both gardener and farmer, should therefore be encouraged for this purpose, for, without them crops in some places would be devoured by mice.—Ed. *Field*.]

## THE GARDENS OF ENGLAND.

### CLUMBER, THE SEAT OF HIS GRACE THE DUKE OF NEWCASTLE.

CLUMBER! The very name strikes one with commiseration, not for the cause, but for the consequence of so noble a place being dismantled, and, from a gardening point of view, converted into a comparative ruin. Situated in one of the finest parts of the "Dukeries," as they are called, in the brave old forest of Sherwood, Clumber has long been regarded as one of the finest baronial residences in England; for, embosomed

heavy, a "catch cold" look about it. The house is supported by a spacious terrace on the south and east fronts, and there is also a small conservatory. Our illustration, from the "Life and Works of Sir Charles Barry," shows the garden front. All the best mansions in the "Dukeries" are singularly unfortunate in their positions, all being low, or, compared with situations they might have occupied, comparatively so. Two minutes' walk north-west, and Clumber might have stood on a piece of table-land, and the same may be said of almost every other mansion in the locality. Unexceptionable sites abound, but, from some inexplicable cause, they have not been selected. Thoresby, with its new mansion, has escaped from the morass, but it might have gone further up the hill and fared no worse. Clumber possesses a fine kitchen garden and a considerable quantity of glass, but most of it is in a very dilapidated state, though some of the houses continue to produce fine Peaches and Figs. Here, too, may be seen some fine old Vines, with stems almost fit for timber, and among them a plant of that finest of all black Grapes, the rarely seen and scarcely known Black Damascus. This Grape, we believe, was brought from Damascus at the time Speechley was a gardener at Welbeck,

Clumber—Garden Front.

amid magnificent timber, with a park such as is rarely met with, a lake which, for picturesque beauty, is almost too much like nature to pass for an artistic creation, there is a charm about Clumber which carries one quite away from the little prettinesses which please for a time in more pretentious places. Here the landscape is of the most delightful description. Whether planted for the purpose or not, the noble trees beside the lake dip their branches into its bosom, and form masses of sweet verdure; while the sighing of the "west wind" through the Cedars and Pine trees, and the wild shriek of the water fowl, almost make one fancy oneself far away by some tributary lake in some primeval forest. Cedars of Lebanon, the Deodar, and Coniferae of the earlier introductions, may be found here in the form of handsome specimens, while of our native trees the name of Clumber is sufficient guarantee that they are worthy of the site which they occupy. The mansion is not happily situated, or, to speak more plainly, it is too low, the ground-floor reception-rooms being but a few feet above the level of the lake just adverted to; and though we have never heard the place spoken of as being unhealthy, it has in the winter season, when fogs are

by the then Duke of Portland, grandfather of the present Duke. It is, therefore, not improbable that the Clumber Vine is one of the original stock. We assisted to transplant the original plant—then not less than forty years old—at Welbeck, in 1832. The removal was a success, and it produced Grapes as large as Orleans Plums, but when the old garden was destroyed, it also had to succumb. SHERWOOD.

M. LINDEN, of Brussels, has lately imported a large stock of young plants of the celebrated Cow tree of South America—the *Palo de vaca* of the Spanish and the *Sandi* of the Indians. This extraordinary tree, the botanical name of which is *Brosimum Galactodendron*, yields milk of as good quality as that of the cow. It flows freely from incisions made in the trunk, and is commonly used as an article of food by the inhabitants of districts where the tree is abundant. The tree grows upwards of 100 feet high, with a smooth trunk 6 to 8 feet in diameter, and without branches for the first 60 or 70 feet of its height. It forms large forests on the mountains and along the sea coast of Venezuela. Humboldt and his companions frequently subsisted upon this milk when lost amid the vast solitudes of the dense forests of the valley of the Amazon.

THE FRUIT GARDEN.

PEARS ON THE QUINCE.

At page 229 you give in "Notes and Questions on the Fruit Garden" a quotation, in which it is stated, that it is supposed that there are more than forty varieties that refuse this union. I will append a list below of many first-class sorts in my collection that have been found here, not to refuse the union, but that will not grow freely after they have united, and I may add that there are many more sorts that take freely and grow for a certain number of years, *i.e.*, from three to ten, but at last succumb to straitened circumstances, that is, the stock is not equal to afford a sufficient supply of nutriment to support them for any lengthened time. Now all these sorts either require to be double grafted, or to be worked on Pear stocks. The list given below comprises the most refractory of the kinds generally classed as of first quality. But it is farther stated that "Professor Decaisne succeeded at his first trial with twenty of these antipathetic varieties without difficulty," it is not clear, from the above sentence, whether the learned Professor succeeded on the Quince only, or on the Quince doubled worked; if on the latter, I do not think any one need fail of success, because the grafts take just as freely double worked as they would do upon a Pear stock not worked on the Quince. It is further said, that both Beurré Bosc and B. Clairgeau obstinately refuse to unite with the Quince; now no Pear that I know absolutely refuses to do so—especially B. Clairgeau. I have one-year-old plants of it, 4 to 5 feet high, and several of them with flower buds—although there are many that will not live long after they have taken; I may mention particularly Marie Louise and Seckel. These two are certainly the most refractory in my collection of 1,800 sorts. But Marie, nevertheless, takes very well double worked on the Nain vert, as also on the Cockspur Thorn. It will take upon the common Thorn, but does not do much good thereon. Before giving my list of refractory sorts, I must call attention to a paragraph at page 230, headed "New Plan for Double-working Pear Grafts." It is given as an American plan, but I must also claim the system, as this week I have been double-grafting to a considerable extent, and the idea struck me, can I not first graft a refractory sort upon one that grows freely upon the Quince, and then put the two grafts so united upon a Quince stock? No sooner thought of than done, whether successfully or not I must wait a few months to see, and will report my success or the reverse. From the extract you have given, I anticipate success. The following Pears are refractory as regards the Quince:—

good result. And although M. Decaisne says that Pomiculteurs are given to exaggerate on this subject, I must repeat, with all due deference to the learned Professor, that my experience goes to support the fact that many sorts of Pears, although they may grow well for a few years on the Quince, will perish at no distant date, or at least become so stunted that their fruit will not be worth gathering. Pears budded or grafted on the Quince, as well as upon the Pear stock, differ very much in their constitution and in the strength of their wood; some growing strongly and freely, others making short and fertile branches. The foregoing 135 sorts are those that do worst upon the Quince, and therefore it is necessary to double graft them. There are besides over 500 sorts that do tolerably well, and under favourable conditions as to soil will grow and bear well for twenty years or more. There are about 500 other sorts that grow pretty freely, and will last for over fifty years and bear well. Besides these there are about 500 sorts in my collection that grow, I may say luxuriate, and I have no doubt would go on bearing healthy fruit for 100 years. The 135 sorts already named are all of first quality. The others include sorts of all qualities. If it will be of any interest to the readers of THE GARDEN, I will give a selected list of all the kinds that are of first quality, and that grow freely and bear abundantly on the Quince when planted in a favourable soil, *i.e.*, in a strong and rather damp loam mixed with gravel or other stones, and I would impress upon all who may desire to grow healthy Pears upon the Quince stock, to always plant their trees a little below the junction of graft and stock—about 2 inches is my own practice, some I know say that the Pear would root above the graft and so render the Quince stock useless, but this is only a rare exception to the rule of their not doing so with me. During twenty years' experience with thousands of trees, and with almost every procurable sort, amounting to nearly 2,000 kinds, I have met with but two instances of the Pear-graft rooting above the stock. One of these instances occurred with myself, and the other with Mr. Warner, of Leicester Abbey, who kindly sent me his tree, making me debtor to the Gardener's Royal Benevolent Institution for £1, which I enclose to you, to be handed over to that institution.

JOHN SCOTT.

Crewkerne, Somerset.

CAUSE OF PEACHES SHEDDING THEIR BLOSSOM.

Two years ago, I planted a very nice healthy Peach tree upon the back wall of a small plant house. There was plenty of room given for the roots, and the proper soil was put in. It now covers the greater part of the wall, having made good fruiting wood each year. The tree seems itself in perfect health; and was this year covered with bloom, which my gardener took great pains to fertilise with a fine brush, and followed the system which, I think, was recommended in one of your papers, *viz.*, to keep the atmosphere low at the time of the blossoms setting. In spite of this, we are now much disappointed at seeing that the greater part of the flowers have dropped off, and I doubt whether there will be more than from a dozen to a dozen and a half Peaches upon the tree. Surely, this ought not to be the case, in a house.

W. B. N.

[Owing to the dull cold weather which occurred in February and March, some varieties of Peach have set very thinly this year, even where great care has been taken to fertilise the blossoms. Without knowing the temperature of the plant house in which your correspondent's Peach tree was kept when in bloom, it is impossible to tell how the blossoms failed in setting. Peach trees, in general, never thrive well on the back walls of plant houses, when much shaded by climbers and other plants, and a damping is created through the watering of the plants, that would render the atmosphere too moist for the trees to set their blooms well in dull weather. Peach trees will set their fruit well in a night temperature from 45° to 50°, and from 55° to 60° in the day-time, in January and February, when the weather is cold. In March, the night and day temperatures may range considerably higher, that is from 55° to 60° at night, and from 70° to 75° in the day time. If your correspondent's Peach tree is planted in too rich a soil, causing it to make strong watery shoots, the bloom, though plentiful, seldom sets so well as that on trees with well ripened wood. If the cause of failure could be traced to this, I should advise your correspondent to lift his tree in the autumn, to root prune it a little, and replant in a shallow, well-drained border, with no manure of any kind in the soil.—WILLIAM TILLERY.]

I have double-worked these this week, and trust to have a

WIRE FRUIT TRELLISES.

It cannot be too often stated that we may greatly improve on the old and too common type of wooden espalier or trellis for fruit trees. It, though made of rough materials, was often expensive and usually ugly. Cheaper at first than a good wire and iron trellis, it soon proved anything but economical, on

account of the frequent repairs which it required. Apart from the question of structure, a too common fault was the lowness of the old espalier; the trees on very low trellises could not attain a fair development, and required much repression. We notice with satisfaction, however, that fruit trellises are becoming greatly improved throughout the country, and this week we figure an example of a light and neat, yet sufficiently strong espalier made by Messrs. Barnard, Bishop and Barnards, of the Norfolk Iron Works, Norwich, for the Maharajah Duleep Singh, in his gardens at Elvedon, near Thetford, Norfolk. This type of trellis is equally useful for trees with their branches trained up in a vertical direction, slender laths placed vertically being used for training the branches in the desired way. The firm who have built these trellises have paid much attention to that kind of work, and have erected many good samples of such trellises.

Equally important with the improved trellises is their improved manner of wiring garden walls, which is so good that it deserves general adoption. Several strong iron spikes are driven into the brickwork of the wall—in the right angle formed by two walls—nails with eyes in them being driven in in straight lines, exactly in the line of direction in which the wire is wanted to pass. The wires are placed at about 19 inches apart on the walls, and the little hooks for their support, also galvanised, are fixed at about 10 feet apart along each wire. The exact distance between the wires must, however, be determined by the kind of tree and the form to be given to it. If horizontal training of the branches be adopted, the wires had better be placed to form

the lines which we wish the branches to follow; if the branches are vertical, we need not be so exact. The wire—about as thick as strong twine—is passed through the little hooks, fastened at both ends of the wall into the strong iron nails, and then made straight and tight by being strained with the *raidisseur*. The wires remain at about the distance of half an inch or three quarters from the wall. If we consider the expense of the shreds and nails, the cutting of the former, the destroying the surface of the walls by the nails, and the leaving of numerous holes for vermin to take refuge in; the great annual labour of nailing, and the miserable work it is for men in our cold winters and springs,—it will be freely admitted that a change is wanted badly. The system of wiring a wall above described, which can be applied to concrete or flint walls as well as to brick, is simple, cheap,

almost everlasting, and excellent in every particular; and it must, before many years elapse, be nearly universally adopted in our fruit gardens. A man may do as much work in one day along a wall wired thus as he could in six with the old nail and shred. Shreds, in fact, can be considered in no other light than as harbours for insects.

Improved Espalier Trellis in the Gardens at Elvedon.

Fruit Wall fitted with Galvanised Wire, in the Gardens at Elvedon.

**Fruit Tree Trellises.**—I see you have increased the number of rods used in forming the trellises, of which you gave illustrations last week (p. 236), from six to eight; and according to the engraving and your description of it, the height would exceed 7 feet and the stakes would have to be upwards of 8 feet, and could not be purchased for one shilling the score, any more than the trellis, so enlarged, could be made for the money stated in the article. It is of great importance that the top tier of branches should be within easy reach of

the gardener's eye and hand, or else you will soon behold a *l'ite de saule* or something very like it. I tried a 7 feet espalier (*Fondante d'Automne*) facing the south, with a wide Grass walk behind it, but I found it better to remove the top bar. It is now about 6 feet 4 inches; all my other espaliers are of the heights I recommended, viz., 5 feet for ordinary purposes, and for southern aspects, with a walk along the north side, 6 feet.—B. S.

## KEEPING LATE GRAPES UPON THE VINES.

It has frequently been asserted that keeping late Grapes hanging upon Vines long after they are ripe exhausts the Vines, and is a fertile cause of shanking, and other evils to which Vines are liable. One writer even goes the length of saying that the practice is as injurious to the health of the Vines as early forcing. That late Vines can be killed by over-cropping, like others, there is no doubt; but I do not think there is one tittle of evidence to show that Grapes hanging late is in the least injurious—even though the fruit may hang till the buds are breaking. The Vines will doubtless bleed if the bunches are not cut off before the middle of March; but that is quite another matter. The time when fruit of any kind acts upon the energies of the plant is when it is swelling, or notably when it is stoning or forming its seeds—the period when shanking begins in Grapes. When Peaches, Cherries, and Plums drop their fruit, and the time generally when all kinds of fruits thin themselves naturally; but Grapes hanging upon the rod after they are ripe are no more burden to the plant than the leafless branches themselves. How can they be? Growth and maturation are completed, and there is no demand upon the Vine. True, the bunch retains its vitality; it will die eventually, as a shoot will if it is cut off the Vine; but further it apparently costs the plant no effort whatever, hang as long it will. Grapes lose flavour every day after they are severed from the Vine; there is no doubt about this, whatever may be advanced to the contrary. Therefore, where the only object is to save the Vines, let the fruit hang as long as possible, for no injury may be apprehended. Bottling has not by any means been uniformly attended with success, even under the most favourable conditions, and it should therefore be a last resource.

I have, perhaps, had as much experience with late Grapes and their keeping as most people. Fifteen years ago, and for years after, I had to do with what was probably the first house entirely devoted to such varieties as Lady Downes Grape in this country, and I can say that year after year, for twelve years to my knowledge (and up till this date for anything I know), those Vines were heavily cropped, and the fruit was never cut till just a few weeks before starting, to prevent bleeding; yet there was never the slightest diminution of vigour in the Vines. Since then, many well-authenticated instances of late hanging, in conjunction with unabated vigour for a series of years, have come to my knowledge, leaving not the shadow of a doubt on my mind in regard to the matter. The late Vinery here has been cropped regularly for the last seven years. During that time shanking or other evils have been unknown, and, though the fruit has been left hanging upon the Vines every year till the end of February or beginning of March, their vigour is remarkable, if heavy, well-finished crops, robust wood and foliage, are any criterion. Such varieties as Lady Downes and Black Alicante are not fit for dessert while such kinds as the Black Hamburgh and others are in season; in fact, they are acknowledged by all to be very indifferent in flavour, not to speak of their objectionably thick skins. It is therefore of some importance to have these in the best condition possible, and this cannot be secured in any way so well as by leaving the fruit to hang upon the Vine as late as is practicable. Much has been written about inside borders for early Vines; but I have come to think that such are quite as necessary for late Vines. A number of the Vines in the late house here are planted entirely inside, and the superior manner in which the fruit keeps upon these, compared with those which have their roots outside, is so marked, that I have decided to fill the house wholly with the former, and do away with the outside ones altogether. J. S. W.

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Flavouring Forced Strawberries.**—When my Strawberries are nearly coloured in the hot-house, I shift them to cool Vineries where they get abundance of air, a plan which improves their flavour vastly. "Your Strawberries are first-rate" said my employer a few days ago, "both in colour, flavour, and size." Koens' is still the best Strawberry for forcing.—G. R.

**Peach Trees from Seed.**—In the United States of America Peach orchards are now, almost without exception, stocked with seedling trees, a practice which of late years has become quite general amongst growers for the Melbourne market. The tendency of some of the best varieties, the Royal Kensington for example, to reproduce themselves true from seed is well known to old cultivators. Since the Peach was badly affected about four years ago, the practice of raising trees from selected seed has become very general, in consequence of the apparent hardness of those that were unworked.—AUSTRALASIAN.

**Frost and Peach Trees.**—The fruit growers of St. Joseph have found out that fruit buds can sometimes endure a lower temperature than they supposed prior to 1872. The limit up to that date was 16° to 18° below zero for Peaches, and 20° for Apples, Pears, Cherries, and Plums. But though the mercury in 1872 marked 22° and 24°, a fine crop of Peaches was grown last year, and hence good hopes are entertained that the still greater cold of 1873 will not prevent another good crop. Much depends no doubt upon the maturity of the wood and the buds when winter begins, a late fall growth with a sudden change to winter leaving the trees in a bad condition for resisting the effects of severe cold.—*Albany Cultivator*.

## TOWN GARDENING.

## TOWN SQUARES AND PLANTING.

PARIS has been much more fortunate of late years in the formation of small ornamental pleasure-grounds in the heart of the city than London. There was a time when foreigners were struck with our "Squares," and their small oases of tolerably green turf and trees growing in spite of the smoke-plague, in the midst of our vast wilderness of dingy bricks and mortar. These "Squares" of ours were imitated in Paris, even to the name, but at first not with entire success. Of late years, however, the progress of the French town landscape-gardeners has been so much more rapid than ours, and the skill and study bestowed upon all the features of town gardens so much greater, that our poor Squares, which originally served as the models for the small town pleasure-grounds of Paris, seem in comparison to grow every day more dingy and desolate. In Paris, on the other hand, every year has exhibited progress in the treatment of small town gardens and ornamental plantations. The edgings of fresh Ivy, the choice and well-grown plants introduced into the borders and in front of the plantations, even in March, a time when the flower borders of Hyde Park are still desolate, and strewn with the wreck of the past season's flowers, rotting on the as yet untouched surface, are sufficient evidence of the energy and skill of those entrusted with the horticultural embellishments of Paris. Annexed is a plan of the nicely kept ornamental grounds which surround the noble old gothic tower of St. Jacques, on the eastern side of the Boulevard de Sebastopol. It cannot fail to be seen at a glance how superior the laying out is to that of any of our own squares and pleasure-grounds.

The plan of the garden of St. Jacques at once suggests one of the features of superiority which distinguish the best plans of this kind, namely, the open centre. In nearly all Paris pleasure gardens the central space is thus kept open, by which means an effect of far greater extent is produced, than when, as with us, the centre is generally occupied by a raised mound densely covered with shrubs. A central mass of that kind at once cuts the space in two, and causes the ground to lose, in appearance, half its dimensions. This curtailment of the apparent size of our town pleasure grounds, which rarely sin on the score of too great dimensions, is an old stereotyped form of plan that ought to become obsolete as soon as possible. It will be seen that the oval lawn of the St. Jacques garden is not broken up by a single tree or flower-bed in the centre, along its entire course. The breaks effected by foliage occur only at the extremities, and along the smaller strips of green at the external boundaries of the enclosure. This keeping open of the central portion is the one secret in lawn-planning, which ought always to be scrupulously observed; for, in addition to its pleasing effect, it gives that breadth of character and grand simplicity which should never be lost sight of in making designs for ornamental gardens, where a general effect of openness and light are the chief desiderata, as in town gardens. It will be noticed also that in the plan of the garden of St. Jacques there is no geometrical repetition of forms; all is easy, and in its flow of graceful lines is made to fall into an apparently unsought conformity with the proportions and other exigencies of the site.

The line of trees at the edge of the footways outside the enclosures is also a pleasing feature. There, as well as in other parts of Paris, such lines of trees have a refreshing and delightful effect in summer, when every yard of shade is so desirable, and when even the mere aspect of the green seems to produce an agreeable coolness. There are many small squares in the heart of London, the enclosures of which might be removed with advantage—the impossible turf be dispensed with, and detached trees planted, either in regular positions, or in picturesque irregularity; beneath which there should be handsome stone seats, and the whole space should be freshly gravelled with bright red gravel every three months, both in summer and winter. Spaces so planted and kept would often produce a most agreeable and, to Londoners, a novel effect. But to return to such rows of trees as those outside the enclosure of St. Jacques; it may be suggested that many of the enclosures of our larger squares are susceptible of being varied

A WELL LAID OUT CITY SQUARE.

by an external feature of a similar kind. Lincoln's Inn, for instance, might certainly be embellished by rows of trees at the edge of the footway, and the open space being large and light, they would, in all probability, flourish luxuriantly if carefully planted. There are several other spaces sufficiently open to admit of such features. Only to name one, what a fine effect might be produced by the planting of two oriental Planes at the top of Langham Place, one on each side of the entrance to the elegant church, with its exquisitely simple steeple, which terminates the vista, and which is considered by many architects the undoubted masterpiece of Nash. The severe character of the acuminating lines of that elongated pyramid, shooting upwards between the green foliage of two noble trees, as it would appear some years hence, would form such a picture as travelling artists in search of the picturesque would not fail to transfer to their sketch-books. It would inevitably become one of the subjects engraved over and over again in tourists' books, entitled "Guide to the Beauties of London," or called "The more celebrated monuments of the great metropolis, described and illustrated by eminent writers and artists;" while at present there is certainly not a single picturesque element in the aspect of Langham Place, for even the artistically designed church and steeple look so bleak and bare for want of support that their real beauties cannot be fitly appreciated. H. N. H.

### WORK FOR THE WEEK. PRIVATE GARDENS.

**Flower Garden.**—The bright weather which we have lately experienced has considerably forwarded the blooming of spring flowers; Crocuses are now everywhere in full bloom, and Hyacinths are pushing up their flower-spikes, whilst Sweet Violets, Dog's-tooth Violets, Daffodils, Narcissi, Scilla sibirica, blue and white, Grape Hyacinths, blue and white, Daisies, Wallflowers, Aubrietias, Arabis, Hepaticas, Pansies, Primroses, and others are all coming beautifully into flower. Turf may yet be laid, lawns formed and sown, top-dressed if required, rolled, swept, and mown. Edgings for flower beds, borders, or walks may now be formed; if the latter are to be of Ivy, the green-leaved Irish kind is the best. In planting, if from pots, disentangle the roots, and stretch out the shoots, pegging them down at intervals, when they will emit roots freely along their stems during summer. The variegated Vine (*Vitis heterophylla*) makes a very pretty edging, or, if supported by means of a few stakes, it may be grown so as to form a clump; it is also a plant well suited for forcing for indoor winter and spring decoration. Periwinkles make good edgings or carpets under the shade of trees where Grass will not grow, and they may now be lifted, divided, and transplanted for that purpose. The variegated *Euonymus radicans*, Japanese Honeysuckle, and Santolinas, all form excellent hardy edgings, equally as suitable for summer and autumn decoration as for spring ornament, and they may now all be transplanted. The red-leaved Ajuga, variegated Arabis alba and lucida, Cerastium Biebersteini and tomentosum, Campanula carpatica and a few others, *Gentiana acaulis*, *Achillea tomentosa*, variegated *Alyssum saxatile*, the Aeneba-leaved Daisy, and the green-leaved double-flowered Daisies, *Viola cornuta*, lutea, and some others, *Gnaphalium lanatum*, *Veronica incana*, *Stachys lanata*, *Dactylis glomerata*, various Saxifrages and Sedums, and most of the *Sempervivums*, the variegated *Polemonium caeruleum*, and several other plants, are very useful as permanent edgings to flower-beds, and when once planted require but little trouble beyond lifting now and then, say once in two years, and rectifying blanks from a reserve stock. Plant out Hollyhocks as back lines to borders, or 4 feet apart in large beds, so as to permit Dahlias, Salvias, &c., to be planted between them. Plant out Pinks, Carnations, Pansies, and a few other hardy plants wintered in frames. If not already done lift overgrown herbaceous plants; divide and replant them in good well-manured soil. Any somewhat tender bulbous plants peeping through the ground are benefited by a mulching of cocoa-nut fibre. Sow seeds of all kinds of annuals on a warm border, and Mignonette and a few other plants that do not like being transplanted should be sown where they are to bloom. Roses of all kinds may now be pruned, using discretion in the operation, for strong growing kinds should not be too severely pruned, whereas stubbier growing sorts may have their shoots shortened to the third or fourth eye, removing at the same time all superfluous wood.

**Greenhouse Plants.**—*Humea elegans* makes a fine conservatory ornament in summer, and for this purpose some of the

strongest plants that can be obtained may be potted in 6, 8, or 10-inch pots, according to their strength, or two plants may be put into each pot, placed in a warm part of the greenhouse, syringed daily, and liberally fed with manure water. Roses in pots for blooming in May should be syringed twice every day, and mulched with well-decayed manure. Transfer all plants in flower to the conservatory, and keep up regular successions. Heaths should now be repotted without further delay, as should also Polygalas, *Eriostemons*, *Leschenanlias*, *Croweas*, *Boronias*, *Chorozemas*, &c. Azaleas should be trained and placed so that all sides of the plants may be equally exposed to the light. All decaying leaves should be removed and a syringing given with well diluted tobacco-water now and then, for the purpose of keeping down thrips. Half-hardy Ferns may now be potted and placed in light frames for a time, or in favourable positions in pits or houses. Greenhouse Palms should likewise be repotted, using good yellow loam, rotten manure, and a little peat for some of the kinds, which should be set in a warm portion of the house. Of bulbous plants, such as Hyacinths, Tulips, Narcissi, and Crocuses, which are now beautifully in bloom, a selection should be made for next year of such kinds as give most satisfaction. The following we have found to be suitable either for purposes of exhibition, growing in windows, or for the decoration of the conservatory, viz.:—

**Single Hyacinths.**—*Dark Blue*—General Havelock, Feruck Khan, Bleu Aimable, Prince Albert, Argus, Baron Van Tuyl. *Deep Red*—Général Pellissier, Solfaterre, Mrs. Beecher Stowe, Macanlay, Von Schiller, Lina. *White*—Mont Blanc, Snowball, Baroness Van Tuyl, Paix de l'Europe, Alba maxima, Queen of the Netherlands. *Blue or Mauve*—Leonidas, Marie, Grand Lilas, Lord Palmerston, Orondatus, Charles Dickens. *Red or Pink*—Gigantea, Grandeur à Merveille, Mammoth, Lord Wellington, Cavaignac, Fabiola. *Yellow*—Ida, L'Or d'Australie, La Fleur d'Or, Bird of Paradise.

**Double Hyacinths.**—La Tour d'Auvergne, white; Louis d'Or, yellow; Noble par Mérite, red; Czar Nicholas, rose; Frederick the Great, red; Grootvoorst, rose; Princess Royal, rose; Lanrens Koster, blue; Bloksberg, blue; Garrick, blue; Lord Wellington, blue; Lord Nelson, blue.

**Tulips.**—*Single*—Koizerkroon; Pottebakker, white and yellow; Thomas Moore, Canary Bird, Belle Alliance. *Double*—Duc Van Thol, Gloria Mundi, Imperator Rubrorum, La Candeur.

**Narcissi.**—Bazelman major, Newton, Queen of the Netherlands, Gloriosa, Apollo, Double Roman.

**Crocuses.**—Aldion, Caroline Clisholm, Sir Walter Scott, Mammoth, Garibaldi, Queen Victoria.

### NURSERIES.

**Indoor Department.**—Everything now under glass is starting into growth, so that a regular steady temperature, a moist atmosphere, and plenty of water at the roots, must be maintained. Shading from bright sunshine should be applied. Testudinarias are throwing out their shoots vigorously; therefore supply them liberally with water, and give the shoots something to adhere to in the form of a branch, a stake, or a string. Enwrap the stems of Tree Ferns with sphagnum, and syringe them twice every fine day, taking care not to damp the crown too much, otherwise the young fronds are apt to rot. Continue to pot stove and greenhouse Ferns, confining them to moderately small pots. Seedlings from amongst the Orchid pots, benches, paths, and other places where young Ferns spring up naturally, and those from seed-pans, should be potted in small pots. Selaginellas, *Isoplepis gracilis*, *Panicum variegatum*, *Convolvulus mammitaniens*, and a few other plants may be divided, planted or potted in light soil, and kept for a short time in a close part of the house; indeed they may be placed under the stages and have a handglass placed over them to maintain an equable moist temperature. Filmy Ferns may be potted in the same way as others, but they must receive a watering overhead previous to being put into the case. Hardy Ferns may be transferred from their winter quarters to cold pits, or to sheltered places between the walls of glass houses. Orchids are now growing freely; therefore gradually increase the heat and water supply, and protect the points of young roots and also flower-spikes from woodlice by means of cotton wool, poison, and different kinds of traps. Phajus, Calanthes, Limnates, Thunias, &c., require a rich and substantial soil, such as a mixture of yellow loam, rotten dung, and leaf-mould, to which should be added some sand or peat. *Trichopilius*, now that they have almost done blooming, may be repotted in rough peat, raised a little above the level of the pot; water them moderately, and keep them in the Cattleya house. Repot *Masdevallias* in peat and sphagnum, and keep them moderately moist in a cool pit; if they have been wintered along with *Odontoglossums* they should now be placed at the coolest end of the house, or else put into a shady pit by themselves. *Maxillarias* may be treated precisely the same as *Masdevallias*, both being increased, if necessary, by division. *Miltonias*, *Oncidiums*, and others are increased by division and specimens of these, as well as of *Cypripediums* and others, are

made by putting several small plants together in a large pot or pan. Dendrobiums that have been lately imported, and that are now emitting roots along their stems, may be cut up into pieces, each having a bud, and used for propagating purposes. Newly-imported Orchids must not be too much excited; plant them in crocks only, or lay them on their sides on some shell or gravel, or keep them attached to the blocks on which they were imported until they begin to grow. Terrestrial kinds are best cleaned and potted immediately after arrival, and kept quiet for a time. Phalaenopsis come home in excellent condition affixed to 2-inch pieces of wood, two inches in diameter, and about two feet in length. Do not disturb them after arrival until growth begins; then saw the pieces of wood into short bits, each having a plant on it, and hang them up with wire to the roof, or wherever other hanging plants are placed. Divide the roots of *Costus elegans*, repot them in small pots, and keep them in a warm, shady part of the stove for a time. Start *Erythrina*s in a warm pit or stove, keep them near the light, and water them sparingly at first, transferring them to a cooler house after the shoots are a few inches in length. The young shoots may be taken off and struck like cuttings in heat. Imported Cycad roots may be potted, and the pots should be plunged in a tan-bed, or other place where a very gentle heat can be afforded them. Repot all small plants of *Anthurium Secherzianum* in a compost of peat, chopped sphagnum, silver sand, and a little charcoal; some prefer a little yellow loam mixed with the peat; plunge them in gentle heat, and shade them from bright sunshine. Plants of *Toxicophlœa* coming into bloom should have a mulching of manure put over the pots to assist their development. Start *Hydrangea*s into growth, use the young shoots for cuttings, and pot off autumn-struck cuttings of them. Japanese Lily-seeds may now be sown in pans set in a warm pit, and after they germinate the young plants may be transferred to a cool house. Start old bulbs into growth, according to their strength and the purposes for which they are required, by introducing them into warm pits, but water them at first sparingly. Late-struck *Chrysanthemum* cuttings should have their points pinched out, and after they are hardened off a little they should be potted singly and placed in a moderately cool house. Autumn-struck cuttings of *Ixoras*, *Gardenias*, *Euonymus*, *Azaleas*, *Passifloras*, *Pentas*, *Hoyas*, &c., should be potted singly as soon as accommodation can be made for them. Young *Azaleas*, *Camellias*, *Cytisus*, *Citrons*, &c., should now be placed in pits by themselves; they like a tolerably brisk temperature, plenty of moisture, and shading from bright sunshine. Under such circumstances young wood is produced early, and by means of three successive pinchings during the summer, good plants are soon obtained.

**Indoor Fruit Department.**—Such Pine plants as are ripening fruit should be taken out from amongst the others and placed in a portion of the pit by themselves, where light and air are more plentiful and the humidity less than would be the case under ordinary circumstances. For Pines in active growth maintain a temperature of from 70° at night; give a little air during the day, and shut up the pits a little before three o'clock in the afternoon, when a gentle dewing from the syringe will be beneficial. Keep the atmosphere moist by sprinkling the passages and walls and keeping the steaming trays constantly charged with water. In early Vineries, where Grapes are beginning to colour, a good watering should be given to the border if inside, mulching it over at the same time with some well decayed manure, so as to render additional watering unnecessary until the fruit is ripe. Continue the thinning of berries, the pinching of shoots, and the regulating of growths, as occasion requires. Muscat Grapes in flower ought to have a temperature of 75° at night, and Hamburgs 5 less. Peaches and Nectarines that have passed the stoning period may be kept at a night temperature of 65°. Give them also plenty of air and moderate supplies of manure water. Remove useless growths, and tie in those required for next year's crops; syringe freely with tepid water twice a-day, and keep a sharp look-out for red spider and mildew. To pot Figs give frequent waterings with manure water, and even a mulching of manure on the surface of the soil invigorates and enlarges the fruits. Pinch the young shoots at the fourth joint, and regulate the quantity of fruit. Early Melons will now be in flower, therefore fertilise the blossoms when there is a sufficient quantity for a crop on the plants. Until the fruit has set, keep the pits well aired and the plants moderately dry, but afterwards maintain a night temperature of 70° or 75°, both for Melons and Cucumbers, and supply the latter freely with water, and when their roots appear above ground, surface dress with an additional 2 inches of rich compost. Continue to introduce successive quantities of Strawberries, and remove to cold frames, and, after a time, plant out those from which fruit has been picked. Such vegetables as have hitherto been forced indoors may now be obtained from the open ground. New Zealand Spinach may, however, be grown under glass for planting out next month.

## THE KITCHEN GARDEN.

### HOME-RAISED POTATOES.

AFTER having given an unbiassed opinion respecting the American Potatoes, I beg to notice such British kinds as have possessed, or will yet possess, a higher reputation. No nation in the world can surpass us in the possession of good Potatoes, and these have been raised for us by those who have made Potato growing and improving the great object of their lives. Perchance in our eager search for quality, we may have lost some of that robustness which formerly characterised our Potatoes, and which is still characteristic of all new importations; but in that case gross growth has been exchanged for quality of the tubers; therefore the balance still remains greatly in our favour. The least advance, however, has been made in respect to that important section—the Early Kidneys. If any one can obtain a good strain of the old Ashleaf Kidney, I feel persuaded that they will produce crops as good and as satisfactory as will any of the more modern selections. Myatt's Kidney is strictly an Ashleaf, and it is a great favourite with the market gardeners, because it is rather the best cropper; but Royal Ashleaf, which is identical with the Improved Ashleaf (and both are good strains of the old Ashleaf), is earlier and better for cooking when lifted, although, as a rule, the tubers are not quite so large. Alma, which is evidently a seedling, is an Ashleaf rather distinct in growth from the others, and one that can be highly recommended, as can also Lee's Hammersmith Kidney, which produces large tubers, and is a heavy cropper. Another new and evidently distinct kind is Early Ranelagh, a kidney of the Ashleaf type, but having a rough netted skin; it is one of the earliest kinds, a good cropper, and boils whiter than most others of this particular section. Some of the new kinds are of better quality than the old Ashleaf, but certainly in no case are they earlier, whilst their cropping qualities have not been sufficiently ascertained for a final decision either in favour of or against them. In this section considerable improvements are yet requisite, for we also want tubers that, when cooked, are white and flowery like Dawes' Matchless, or we want the Lapstone engrafted on an Ashleaf growth, and with all its features of early ripening. Our best early round Potatoes are Turner's Union, a white-skinned kind, combining the earliness of the Shaw with some of the better qualities of the Regent; Scotch Blue, a very handsome shaped tuber of excellent quality and the whitest of flesh; Onwards, one of Mr. M. Fenn's old seedlings, and a most delicious Potato; and Early Red Emperor, alias Main Crop, a red-skinned variety that is a great improvement upon the Fortyfold, and without exception the most handsome round Potato that we possess. Mr. Fenn, who occupies amongst Potatoes that position as a raiser that Mr. Laxton does amongst Peas, has now some new early kinds that promise to be great acquisitions to those who can appreciate high quality in Potatoes. In his Early White Kidney is presented one of the best and whitest of early sorts, and an excellent cropper. Amongst round Potatoes his Eliza Fenn and Early Market, with a few others, possess an excellence that must make them eagerly sought for, whilst his Rector of Woodstock, a new second early round, extremely handsome and first-rate Potato, has already received high awards, and must eventually become a great favourite. In English Rose Mr. Fenn has a round and handsome kind, and his new red-skinned Kidney Bonntiful is not only an immense cropper, but is, without exception, the most handsome red-skinned exhibition Kidney that can be found. The mention of these will sufficiently indicate what that gentleman is doing to promote Potato improvement, and when we remember what Bell & Thorpe, Paterson, Taylor, and others have done for the same cause, we have reason to rejoice that Potatoes are not likely to deteriorate in our hands. Second Early Kidneys present to the gardener possibly the most valuable section from which to select stocks for the main crop, and from these none are superior in all general excellence to Waterloo, Beaconsfield, an early Lapstone, Dawes' Matchless, Excelsior, King of Potatoes, King of Flukes, and President, all of which are heavy croppers and have handsome smooth tubers in which there is no waste, whilst their qualities, though of a high order, still differ enough to satisfy the most divergent tastes. They will, with ordinary care, keep until new Potatoes are ready for lifting in June.

A. D.

**New Tomatoes.**—The Trophy came out first best in a trial of field culture of Tomatoes, on the grounds of the Illinois University last season, being as Mr. Vickroy reports, "at least 75 per cent. better than anything we have tested." The next most satisfactory were New York Market and Early Smooth Red.—*New York Tribune*.

**American Potatoes in England.**—I agree with "A. D." in his remarks on these in p. 23 of THE GARDEN, with the exception of what he says respecting the Potato called Climax, which he describes as a large, coarse, deep-eyed tuber, never handsome. The variety I have got under that name is quite the reverse of that, being slightly oblong, perfectly level all over, and so handsome that it is termed here the "Pretty Potato."—R. GILBERT, *Borghly*.

## CULTURE OF PARASITES.

(MISTLETOES.)

WHEN staying a short time ago at Matlock, I took the opportunity of visiting the nursery of Mr. Smith, of Darley Dale, and among other interesting objects there, I saw some fine specimens of Mistletoe growing upon certain Apple trees. The parasite in question is doubtless *Viscum album*, but, although closely allied, and in general appearance closely resembling *Loranthus europæus*, which is parasitic on the Oak in Central Europe (especially about Vienna), the floral and frutescent differences definitely separate the two; and as the former is generally found on the Apple, Pear, Poplar, &c., and rarely, if ever, on the Oak, of which the latter is the especial parasite, it seems probable that the *Loranthus* is the true Mistletoe of the Druids, and to an ordinary observer differs from *Viscum album* only in the berries being yellowish instead of pearly white; the flowers of the one are sessile, and those of the other pedunculate. The relationship of both these parasites to our invaluable town shrub, the Aucuba, is significant of possibilities in the way of growing them in our suburban gardens, which it is to be hoped will be made the subject of patient and careful experiment, especially as the approaching exhibition at Vienna will afford facilities for horticulturists to go over there, observe the *Loranthus in situ*, and procure plants and berries. "The propagation of the ordinary Mistletoe in British nurseries," says London, "has scarcely been attempted, but nothing could be easier on Thorns or Crab Apples planted in pots for convenience of removal. Perhaps if it were propagated on shoots of the Poplar or Willow, truncheons of these trees with plants of Mistletoe on them might be taken off, and planted as cuttings, without injuring the parasite."

Allow me to ask—Do any of your readers know of any Oak tree in England on which Mistletoe is growing, and if so, will they take the trouble further to ascertain whether it is not *Loranthus europæus* and not *Viscum album*? To say simply it is the Mistletoe is not sufficient. How curious it would be if it were discovered that the true Druidical plant had disappeared from Britain, as *Papyrus antiquorum* is reported to have disappeared from the Nile; and if the former were this year to be reintroduced to England from Austria, and the latter restored to Egypt from an English or French conservatory. For any one who has leisure and opportunity for a little archeological research and cares to definitely settle a moot point, I would suggest the collection of evidence as to whether the Druidical Mistletoe had white berries or yellow ones, and whether there exists any sculptural or pictorial representation showing the flowers or berries with or without a footstalk. Seeds of the ordinary Mistletoe have been ascertained to germinate with facility, irrespective of a nutritive nidus, the only apparent condition of success being a suitable degree of humidity. Du Hamel (possibly with an idea that the plant was epiphytal and not parasitic) made Mistletoe sprout on dead branches, bricks, tiles, stones, soil, &c., but they merely sprouted and did not live. M. du Rochét actually sprouted them on the frame of a window and observed that the radicles directed themselves towards the interior as if in quest of darkness. London observed that germinating on the upper side of the branch of a Lime tree the shoots tended upwards; those on the under side downwards. Since these and other patient observers made their experiments Wardian cases have been invented and popularised. Let us hope that some of the many who possess one will take up the study of this curious plant for the cultivation, preservation, and close observance of which the Wardian case affords facilities formerly unknown. The plant has already been ascertained to be a true parasite and not an epiphyte, i.e., it can only grow and increase at the expense of such living tissue as its roots may attach themselves to for food as well as mere support; its rhizomata traverse the inner bark and have a tendency to re-assert and develop themselves in a way that may be popularly described as "throwing up suckers." Finally, I see no reason why the two similar but yet different plants—*Viscum album* and *Loranthus europæus*—both of the same natural order (*Loranthaceæ*), to which order also the Aucuba was at one time thought to belong, should not be easily grown in a Wardian case, and so become objects of universal interest, both social and scientific. Imagine the charming appearance of a pot specimen Aucuba in fruit with Mistletoe also in fruit upon it! The prizes and high prices obtained for novelties ought surely to tempt nurserymen to try for the production of this desirable probability. To the vegetable physiologist I deferentially suggest an attempt to convert a parasite into a terrestrial plant, by germinating or engrafting the Mistletoe on the roots of a seedling Aucuba. Those who possess Orchid houses have every facility for experiment upon the exotic species of India and South America, such as *Viscum opanthoides* (*V. attenuatum*?), which might be procured from Bombay, as it is common on many kinds of trees at Mahabuleswar, especially towards the Rotunda Ghant; or, preferably *Loranthus*

*obtusatus*, *L. longiflorus*, *L. amplexifolius*, *L. lagaeniferus*, &c., which may be found on Mango and other trees at that easily accessible place—Khandalla; the flowers of some of these are showy enough to claim admission as flowering plants, especially *L. amplexifolius*, which the natives call "Baingooloo" (with red flowers), *L. longiflorus*, with flowers like a Honeysuckle. The rarer species—*L. obtusatus*—may be found at the Rotunda Ghant, Mahabuleswar; it flowers in long racemes. Let me further add that the habitat of these plants, Mahabuleswar, Matheran, Khandalla, &c., are the hill stations near Bombay, to which Europeans resort in the hot season; but, although many who may read this, and have friends there, may think it an easy matter to procure them by merely writing out to them, it is very difficult indeed, as I know, from personal experience; and I suggest that residents at these sanatoria be requested to offer rewards to the Ghantiers for all specimens of "Baingooloo" they bring in, and that notes be taken and attached to each specimen, recording locality, tree on which found, colour and character of flowers, time of flowering, &c. The native name of the tree is quite sufficient, indeed preferable, and less likely to cause mistakes than such a vague statement as "on a kind of Ash," or "a tree like the Mountain Ash," &c., which Europeans might be only too ready to state with respect to *Melia Azadirachta*, for instance. Any assistance that I can give, either by detailed advice or translation of native names, is cheerfully offered to any of your readers willing to undertake the experiment.

WASHINGTON TEASDALE.

Hawthorpe, Leeds.

## LAW NOTES.

**Erskine v. Adeane.**—This was a case respecting the poisonous properties of Yew, and the duty of persons who happen to have noxious plants, shrubs, or trees growing on their lands. The applicant's case was that he had lost thirty-six lambing ewes out of a flock of 220, and about 100 lambs, owing to the ewes browsing on the Yew trees at the side of one of the plantations on his farm. It was questioned whether growing Yew is a poison to sheep, and some instances were given in which sheep were observed to browse on green Yew with impunity. Other instances, however, to the contrary were cited; and it was said that, in the winter of 1839, a herd of more than 200 deer belonging to the Duke of Northumberland died of eating green Yew, which they got at by crossing a river on the ice. Upon the whole, the evidence seemed to support the notion that growing Yew may or may not be fatal to a cow, a horse, a sheep, or a deer, according to the strength and constitution of the animal; but that partially-dried clippings of Yew, which are in a state of fermentation, are almost invariably fatal. The Master of the Rolls was of opinion that the ewes and lambs died of eating Yew, and decided against the respondents, on the broad ground that as, between landlord and tenant, there is an implied warranty on the part of the former that the trees and shrubs which he plants or suffers to be on the demised premises shall not be noxious or injurious to the tenant, and directed an inquiry to what compensation the applicant was entitled.

**Waterer v. Waterer.**—This case came on upon further consideration. The testator in it was a nurseryman and market-gardener, who died, leaving very considerable real and personal estates. The questions argued were—1st, whether certain of his devised real estates, which had been "used" by his sons as partners in his business after his death, had been so dealt with as to have become partnership property; and 2nd, whether, being such, they were converted from realty into personalty. Lord Justice James held that the real estates principally in question were so "involved" with the business as to be "partnership property," and were converted from realty into personalty, and made a declaration accordingly.

**What Constitutes a Removable Greenhouse?**—Will any of your readers oblige me by stating whether a wooden-built greenhouse or orchard-house, with posts let into the ground, is a tenant's property? I am aware that a tenant cannot break the soil, but I presume he may saw the posts at the ground level, thus the building would, I should think, be regarded as the tenant's. If not, I can as easily erect such a building, standing upon one course of bricks, and as to this I suppose there can be no question.—A SUBSCRIBER, *Hedwiga*.

THE exquisite charm of spring's first ringing laughter  
We measure only by the winter's gloom;  
The wailing winds, the whirling snows, make room  
In our half-frozen hearts for sun-shine after!  
If every morn were fair and all days golden,  
And only emerald turf our footsteps trod,  
Our sated souls would tire of velvet sod,  
Our eyes in spells of snow-capped peaks beholden!  
We gauge the flow'et's beauty by the mould  
That lies so long and dark its sweetness over;  
As absence makes his rapture for the lover,  
Who sees no light till he fond eyes behold.  
So God be praised for wintry blasts and snows,  
That end their lessons when the Violet blows!

## SOCIETIES, EXHIBITIONS, &amp;c.

## ROYAL HORTICULTURAL SOCIETY.

(APRIL 2.)

THE weather on this occasion was exceptionally fine; but subjects of exhibition were somewhat limited compared with what might have been expected.

**Roses.**—These formed one of the chief features of the show. A collection of sixteen dozen cut blooms was furnished by Mr. Wm. Paul, of Waltham Cross, all of which were remarkably fine, and well deserving the extra prize which was awarded them. Conspicuous among them were *Pierre Notting*, Duke of Wellington, Alfred Colomb, Horace Vernet, Xavier Olibo, and Princess Beatrice. Messrs Paul and Sons, of Cheshunt, also exhibited some excellent cut Roses, amongst which were *Horace Vernet* (extremely fine), Fisher Holmes, Madame Victor Verdiere, Baronne de Bonstetten, Duke of Edinburgh, Dr. Andry, Abel Grand, Princess Louise, La France, and Madame Alfred de Rougemont—all Hybrid Perpetuals. Of Noisettes and Tea-scented Roses, the same exhibition comprised *Souvenir de Paul Néron*, Marechal Niel, *Souvenir d'Elise*, Vardou, Catherine Mermet, Cheshunt Hybrid (fine), Belle Lyonnaise, *Narcisse* (fine), and Madame Villermoz. The new Tea-scented Rose, called Cheshunt Hybrid, was also exhibited by Messrs. Paul and Son. It is purplish-red in colour, large, very double, and powerfully fragrant. Messrs. Veitch and Sons contributed a group of well-flowered Roses in pots, also a large and fine collection of cut Roses; amongst them were Duke of Edinburgh, Mrs. G. Paul, Abbé Bramere, Prince Camille de Rohan, Madame Lacharme, Madame Levet, and others. Groups of President Thiers, Richard Wallace, and Lyonnaise were shown by Mr. H. Bennett, Manor Farm Nursery, Stapleford.

**Orchids.**—In the nurserymen's class for six distinct *Odontoglossum*s, Messrs. Veitch were first with fine specimens of *O. Phalaenopsis*, *nivenum majus* (very fine), *Pescatorei*, *triumphans*, *oloratum* (fine), and *Alexandra*. Mr. W. Bull was second with some good plants, especially of *O. Alexandra*. In the amateurs' class for the same, Mr. W. Denning was the only competitor. Messrs. Veitch & Sons furnished a collection of Orchids in which was a specimen of *Cypripedium villosum* 30 inches in diameter, and laden with flowers; *Angreæum sesquipedale*, with four fine blooms; *Odontoglossum nebulosum*, with large pure white flowers, faintly marked with yellow on the lip, but having no spots on the petals or sepals; *O. Halli*, fine; *O. pulchellum*; *O. atropurpureum*; *Cymbidium eburneum*, and others. Mr. Denning, gardener to Lord Lonsborough, contributed a group of Orchids, amongst which were the extremely beautiful *Masdevallia Lindenii* and its orange-red congenere *M. ignea*; a grand example of *Odontoglossum hystrix*; two fine plants of *Oncidium obryzatum*; *Warszewiczella discolor*; *Dendrobium aggregatum*, with pretty yellow flowers; *Trichopilia*s, and other beautifully-flowered plants. From Mr. Fairbairn, Peterborough House, Fulham, came a group of Orchids in flower, among which was a large and well-bloomed specimen of *Cypripedium villosum*, a nice plant of *C. hirsutissimum*, a good plant of *Aerides Fieldingii*, with two fine flower-spikes; *Cattleya Skinneri*, with two good spikes; an extremely well-grown plant of *Anacochilus Lowii*, and one or two others.

**Cinerarias.**—Good specimens of these were exhibited by Messrs. Dobson & Sons, of Isleworth, who gained the first prize in the nurserymen's class for nine, and Mr. James, of Isleworth, was equally successful in the amateurs' class for six. A collection of very beautiful Cinerarias, with large well-formed and brilliantly-coloured flowers, was also shown by Messrs. F. and A. Smith, of Dulwich.

**Miscellaneous Plants.**—From Messrs. Osborn & Sons, Fulham, came a remarkably fine group of these; conspicuous amongst them were some good varieties of *Anthurium Scherzerianum*, one especially being remarkably fine; also an excellent plant of *Maranta Makoyana*, *Pandanus Veitchii*, *Dieffenbachia Bansei*, some graceful and elegant little Palms, particularly *Bomarea fissus*, and other flowering and fine foliaged plants. A collection of plants, furnished by Mr. B. S. Williams, comprised some very fine *Cyclamens*; also, *Amaryllises*, *Aralias*, Palms, *Yuccas*, and some Orchids, but the most showy plant in the collection was a magnificent specimen of *Imantophyllum miniatum*, bearing ten wonderfully fine heads of orange-red flowers. A group of small Clematises in flower was exhibited by Mr. Noble, of Sunningdale, who, in addition to those staged for exhibition only, received a first prize for half-a-dozen distinct kinds. A group of ornamental-flowering and foliage plants was contributed by Mr. J. Aldous, Gloucester Road, South Kensington, and Mr. Croucher, gardener to J. Peacock, Esq., sent a specimen of *Beschorneria tubiflora Jacobi* in bloom. Mr. Ware, of Tottenham, furnished a remarkably fine collection of hardy plants in flower. Messrs. Rollisson & Sons, of Tooting, in addition to a dozen superb specimens of *Mignonette*,

showed some very fine hardy *Primulas*, a basketful of the beautiful silvery-leaved *Echeveria pulverulenta*, and the remarkably distinct thick-leaved kind called *E. Agavoides*. For the best six hardy distinct *Primulas*, Mr. Ware was first with well-flowered plants of *P. altaica*, *nivalis*, *acaulis sulphurea fl. pl.*, *acaulis alba fl. pl.*, *acaulis lilacina fl. pl.*, and *acaulis var. Purity*; Mr. Early, who was second, also had good plants. For six bulbous plants in flower Mr. Ware was also first with *Tulipa sylvestris*, *Narcissus Bulbocodium*, *Muscari botryoides*, white and blue; *Scilla Ughii*, and a good variety of Dog's-tooth Violet. A large collection of *Narcissi* was exhibited by Miss Florence M. Barr, and by Mr. R. P. Barr, 10, New Road, Lower Tooting; also by Mr. Ware, of Tottenham.

**Vegetables and Fruit.**—A remarkably fine collection of forced salading was exhibited by Mr. J. Hepper, gardener to C. O. Ledward, Esq., The Elms, Acton, to which a first prize was awarded. It consisted of Hardy Hammersmith, Green Paris Cos, and Grand Admirable Lettuces, four kinds of Endive, Williams' Matchless Celery, Chicory, a brace of Telegraph Cucumbers, Curled Parsley, Golden, American, and Water Cresses, Mustard, Curled Chervil, Dandelions, French Sorrel, Wood's Frame and French Breakfast Radishes, Dell's Crimson and Pine Apple Beets, Tarragon, and Corn Salad. Mr. Hepper also exhibited some good French Beans, consisting of Fulmer's Early Forcing, a dish of Figs, for which a cultural commendation was awarded, and some Princess of Prussia Strawberries. A dish of Keens' Seedling Strawberry also came from Mr. J. Miller, Work-sop Manor, Notts, and a dish of Citrons from Mr. J. Lee, The Crescent, Surbiton. Messrs. Osborn showed some of their Winter White Broccoli, the heads of which were large and good. Mr. Cooling, nurseryman, Bath, also showed some of his Matchless Winter Broccoli, the heads of which were compact, white, and very fine.

**Cucumbers.**—For a brace of black spined Cucumbers Mr. Douglas, of Loxford Hall, was first, with a remarkably fine brace of Blue Gown, measuring some 20 inches in length. The same grower was also first in the class for a brace of smooth Cucumbers with Tender and True, each of which was longer than his Blue Gowns and quite as fine. The best white spined brace (*Pizzey's Favourite*) came from Mr. D. Pizzey, Fulmer, Slough; these were wonderfully fine and received a first prize.

**First-class Certificates.** These were awarded to the following:

- To Rose Lyonnaise (Paul & Son), a pink Hybrid Perpetual of great promise.
- To Rose Lyonnaise (Bennett).
- To Rose President Thiers (Bennett), a beautiful bright crimson Hybrid Perpetual.
- To Rose Richard Wallace (Bennett), a fine crimson coloured Rose, with double well formed flowers.
- To Rose Madame Jules Margottin (Bennett), a pretty pinkish yellow Tea-scented variety.
- To *Amaryllis Beauty of Reigate* (Broom), an extremely fine crimson kind.
- To *Primula purpurea* (G. F. Wilson), a very pretty kind with purple flowers.
- To Broccoli Cooling's Matchless Winter (Cooling), an excellent large solid, pure white kind.

## FLOWERS FOR THE POOR.

ALL those who have visited much among the London poor, whether in workhouses, hospitals, or in their own homes, have stories to tell of the softening influence of fresh flowers. We have heard of doors, which were resolutely closed against the district visitor, being first opened to receive a bunch of Primroses—after which the visitor was always welcome. Of late years much has been done by the window-gardening societies. Few London districts are now without one; and, from the day when the plants are brought by the exhibitors to be registered to the day fixed for the final show, a new life is imported into the family. The plant has to be cleaned, watered, trained, and sheltered alike from dust within and storms without. At last the great day comes; and with what honest pride the exhibitors carry their pots to the appointed spot, and with what intense anxiety do they await the decision of the judges as to the awarding of the prizes! Each class has its separate division in the tent or room where the show takes place. There is a workhouse class, a hospital class, a general class, and a children's class. The morning is generally occupied in arranging the classes. Early in the afternoon the doors are open to shilling visitors; later on the public are admitted at a penny; and this is the pleasure which many and many of the working classes have been looking forward to through the spring. Flags are flying on the green grass, a band is playing, and the rich and poor meet together—the one to admire what the other has cultivated under such manifold difficulties; children are seen dancing in one spot, playing at games in another; all ages are collected—

even the very old creep in, to have one bright day in the year. Then, as the shades of evening set in, preparations are made for the distribution of prizes, and the mass of visitors congregate round the platform raised for the speakers. What a proud moment for the individuals whose names are called out to come forward to receive the medal or money awarded! Sometimes the successful candidate has been so small a child that it had to be lifted up on the platform. The proceedings generally end by the singing of the Doxology, and then long trains of flower-bearers are seen wending their way home with their precious possessions. It was seeing the delight given by these days, and knowing from experience what a love the poor have for the beauties of nature, that led to the consideration how far this wholesome and innocent taste could be extended, and whether it would not be possible to procure a weekly supply of cut flowers from country friends to distribute amongst the various classes to whom they would be such a boon.

First on this list would come the incurable wards of our great workhouses, where are to be found men and women, many of whom have known better days, and who have had homes, and may be gardens, of their own, who are now ending their lives on a narrow bed, their only view the cold whitewashed walls around them, their only companions fellow-sufferers on adjoining beds, their only change the release of one of these sufferers from his or her earthly bondage and the arrival of another to take the vacant place. Weeks, months, and years—yes, even ten or fifteen years—are spent in this cheerless atmosphere. Of late years much has been done to alleviate the state of these dismal abodes by allowing a staff of Visitors to come in, but formerly no break ever occurred in the monotonous round of workhouse life. Besides workhouses there are general hospitals, asylums, and other institutions, whose inmates would be cheered and gladdened by the sight of anything green. Then there are the sick, the old, and the lonely in their own wretched homes in the back courts and alleys of our great metropolis. Great attempts are annually made to give school children and others country treats, and such days are in most cases the only sight they have of green fields and unsmoked trees. Surely if one day of country sights is such an enjoyment, will any one grudge the little time and trouble it would take to organise some plan by which flowers and verdure could be brought each week to those who are deprived of them? For two years the experiment was made by a lady in Belgravia. She was living in a house which lent itself admirably to the plan. From the main thoroughfare a narrow flagged passage led to a small enclosed garden, into which opened the front door of a verandahed cottage covered with creepers—one could not help thinking it might have been a shooting-lodge at the time when Belgravia was a snipe marsh, and that the improvers of modern days had overlooked its existence. Miss ——— appealed to her country friends privately and through the daily papers, and many gladly responded.

An application for a share of the flowers thus sent was made by the chaplain of one of the large lunatic asylums in London—"To the sick in mind they will be a great boon;" and he conveyed the opinion of the medical officer as to the result of the donations:—"He places the highest value on the kind weekly gift of flowers to the patients of this hospital. The inquiries were endless as to when the flowers would come again. The pleasure of arranging them for the different wards and wings was great, and many a sad hour of depression has been cheered and lightened by the kind gift, and we shall be only too glad in due time to welcome the flowers again. The boon of them in one of the smokiest and dullest parts of London is untold."

Such was the result of the experiment on a very small scale; why should it not be extended? Every lady visitor to a workhouse or hospital has a circle, more or less extensive, of country friends. Could it not be arranged that four of them should each engage to send up a hamper one week in a month? What an enjoyment to a sick or incurable ward it would be to look forward to one day in the week when they would see what was bursting forth in the country, and so be able to follow the successive seasons by their flowers! What a pleasure to the convalescent to unpack these hampers and carry the contents to the bedsides of those who cannot move! For the poor in their own homes surely it would not be difficult to find in each locality some spare room (even the parish schoolroom on a Saturday afternoon, which is always a holiday), in which to receive and distribute such country contributions; a very little experience would prove what flowers lasted best and were therefore best worth sending. How many energetic young ladies there must be who spend the whole year in the country, and who probably envy their town friends their opportunities of doing good, but have never thought of the pleasure they could give by sharing their country luxuries with Londoners; and unless there were some system it would be useless to send up flowers for the chance of their being made use of; but we feel sure many would gladly assist in this work

if they were put in the way—and the flower packing in the country would give almost as much pleasure as the unpacking in town. One of Miss ———'s contributors assured her that it had awakened a new sense amongst his school children, and that he was obliged to make it a favour as to who should be allowed to bring a nosegay for the London basket. It would also call forth both the taste and ingenuity of country people in arranging and packing flowers.

The objections that have been made are that the flowers would die before they reached their destination; but why should they die sooner than the weekly hampers that come up to decorate dinner tables and ball-room? Many of those sent to Miss ——— were often preserved for a fortnight. "We change the water every morning, and put a bit of salt in, and that keeps 'em fresh." Another objection was that the carriage costs nearly as much as the flowers could be bought for at Covent Garden. We answer No. The carriage seldom exceeds one shilling and sixpence, and often is very much less, and for that sum a very small quantity of flowers could be bought; whereas a hamperful supplies between twenty and thirty persons, and few would scruple to pay a shilling per month when so much pleasure is given by it. Of course there must be some amount of time and trouble bestowed both by the senders and receivers—but what can be done without trouble? (and we do not call upon those whose time is better employed to assist)—and how many ladies there are in London who are too young or not strong enough to visit among the poor, who would be very glad to do something! Here is employment for them, harmless alike morally and physically, and yet giving a great amount of pleasure. What a pleasure a parish depot of flowers well supplied each week would be! District Visitors would know where to send for nosegays for their sick, and it might benefit a higher class. How many an invalid in the middle and even upper ranks of life would rejoice in finding flowers within their reach,—single ladies, reduced in circumstances, who never can afford in the lonely hours of their latter days the luxury of what they had in profusion in their youth, when all was bright. To carry it out thoroughly it ought to be kept up during the spring and autumn,—not only in the summer months. Nothing answers better in London than Snowdrops, Daffodils, Primroses, and Violets. What baskets full of these might not be gathered by school children, and mixed with Ferns and evergreens! Then in the autumn, when the over-worked higher classes are all going out for change and rest, what is the only change that our poorer brethren experience? Less work, less help, and fewer kind faces to visit them and cheer them onward on their toilsome road. We have gone out to visit our friends in their country houses, and wandered through their well-kept pleasure grounds and brilliant flower gardens—a couple of flowers per week from each of those well-filled beds would fill a hamper, and gladden the hearts of many of those poor souls to whom change and rest are unknown. The poor who were made so happy by the flowers last year are already beginning to ask, "When shall we have our posies again? They were a pleasure to us." And truly God's natural beauties preach sermons to the hearts of the poor. "I was walking in the park last Sunday," said an old woman, "and when I saw all the trees budding out, I could not but ask myself, Is there any good budding out in me?"

Will any one kindly assist in this "new missionary work" here in London? Any contributions of flowers, or any suggestions towards extending the plan, may be addressed to Miss Stanley, 22, York-street, Westminster, who will gladly receive them, and will undertake to carry out the plan in that locality.—MARY STANLEY, in *Macmillan's Magazine*.

## COVENT GARDEN MARKET.

APRIL 5TH.

New Grapes are coming into the market rather plentifully, and the old ones are yet in excellent condition. Strawberries are first-rate and in good demand. Green vegetables are becoming scarce, and are likely to be so until relieved by spring crops.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Chestnuts, per bushel, 12s. to 20s.; Cobs, per lb., 2s. to 2s. 6d.; Grapes, hothouse, per lb., 15s. to 35s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 4s. to 10s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 6s. to 10s.; Strawberries, per oz., 1s. to 2s.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 5s. to 10s.; French, 15s. to 30s.; Beans, Kidney, per 100, 2s. to 3s.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, 6d.; Cauliflower, per doz., 3s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 6d. to 2s. 6d.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz. 1s. to 2s.; Mushrooms, per pottle, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 3s. to 6s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 4s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 5s. to 8s.; Potatoes, per bushel, 1s. to 8s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsafy, do., 1s. to 1s. 6d.; Savoy, per doz., 2s. to 3s.; Scorzoner, per bundle, 1s.; Seakale, per basket, 1s. to 2s.; Shallots, per lb., 3d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, per bunch, 3d. to 6d.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### BUTTON-HOLE BOUQUETS AND COAT FLOWERS.

BUT few seem to understand that there is any difference between a button-hole bouquet and a coat flower; yet there is, and a very great difference too, the flower being, as the word signifies, a single bloom, whereas a bouquet means a number of flowers arranged according to taste. Many papers have appeared in different horticultural periodicals on the arrangement of cut flowers, and yet, with few exceptions, they have excluded button-hole bouquets, probably because, being small, people imagine that they must necessarily be easy to make. Just let them try, and I do not hesitate to say that they will find themselves much mistaken, as no combination of flowers requires to be put together with more taste, or to be more lightly done, than a properly made button-hole bouquet. Flowers selected for this purpose should always be good, particularly those for mounting singly, which should, in fact, be specimens of whatever kind is chosen. Ferns I always like to see in such bouquets, and also along with coat flowers, pro-

Button-hole Bouquet.

vided these are stove or greenhouse kinds; but hardy flowers I like best mounted with their own foliage alone. Nearly all flowers for bouquets of any sort should be wired; indeed, many could not be used for that purpose at all were they not mounted on wire, as, for example, the pips of white Hyacinths, which, in winter, are among the most useful flowers which we have. There are, however, other ways of mounting flowers besides wiring them. Let us take, for example, a Gardenia. The centre petals of this flower—indeed all except the outside row—are very even and lovely; but their beauty is somewhat marred by the outer ones, which look twisted. Now to remedy this evil, and to make them look all even, proceed as follows: Take a common Laurel leaf, and cut a piece out of it about an inch square; with a pair of scissors trim round the corners, so as to almost make it circular; then cut a cross in the middle, and down through that push the stem of the Gardenia until the flower and the Laurel leaf are pressed tightly together; then hold it upside down, and through the stem, close to the leaf, pass a "stub" wire (which will keep the leaf in its place); bend the ends down, and fasten them together with a little binding wire so as to form a stem. The petals of the flower can be then arranged out in their proper places, and the piece of Laurel leaf being so tight to the flower they will remain wherever they are placed. There is also another point to which I would wish to direct attention,

and that is, the foundation of the button-hole bouquets, which is generally a piece of Maiden-hair Fern; but that is not stiff enough in itself to form a good support for the other flowers. To remedy this, the best plan is to back the Fern with a small Camellia leaf, wired, which will keep the whole bouquet firm and in shape. The following arrangement is that most often seen; at the back is a spray of Fern; next some long light flower, so as to form a kind of point or finish at the top; then a Camellia bud, or Rose, or some such flower, and then Maiden-hair Fern and whatever other small flowers are at hand. The bouquet of which the accompanying is an illustration is composed of a white Camellia bud, Lily of the Valley, blue Scillas, &c., and Maiden-hair Fern. I made one a short time ago of a half-open white Camellia bud, spray of *Hoteia* (*Spiraea*) japonica, and a few pips of white Hyacinth, mixed with a little Maiden-hair, and many remarked that it was very light and elegant looking. That which took the first prize at the Royal Horticultural Society's Show at Birmingham last summer was composed of a yellow Rose-bud mounted with blue Forget-me-Not, a pip of *Kalosanthes coccinea*, and one of *Bourvardia*. I have seen one made of Lily of the Valley, a blush-coloured Rose-bud, and the same shade of Hyacinth pips, with a little Fern worked through it, which was a very neat-looking little bouquet; another consisted of a spray of Lily of the Valley, a yellow Rose-bud, and a few pips of a rich purple *Cineraria*, which came out well against the deep colour of the *Maréchal Niel* bud. I could give descriptions of many others, but think that those which I have mentioned will suffice to show the best shape and style in which such bouquets should be made. A. H.

### KEEPING GRAPES IN BOTTLES OF WATER.

MUCH that is unsupported by fact is being written in some gardening periodicals about the keeping of late Grapes in bottles of water. The advocates of the system, who know anything about it, only contend that there are great advantages in cutting off the bunches of late Grapes, say in February or March, on purpose to get the Vines pruned and properly dressed. I used at one time, year after year, to keep the bunches of Lady Downe's Seedling hanging on the Vines until the beginning of May, when the flow of sap began to burst the berries, and the bunches were hidden by the young shoots. Now, since I have put the bunches in bottles of water, I can keep the same variety in good condition until the middle of June, and have certainly given the Vines more strength and done them more justice by doing so. It is said by some, why keep late Grapes until that season, when early Grapes can be ripened in April or May? Gently, ye doubters; look at the present price of coals for early forcing, and the price per pound that would have to be charged for these early forced Grapes in the market in order to make their forcing profitable. I have heard from my friend Mr. Thomson that, in his great Vine-growing establishment on the banks of the Tweed, he will trust to his crops of late Grapes to bring the most "grist to his mill." Late Grapes carry better to the market than early forced ones, and they bring remunerating prices when the ruck of the Hamburgs and Muscats is over. By all means let Grapes hang on the Vines when ripe in the summer and autumn, and even up till February, should no bedding-plant exigencies stand in the way of their keeping; but after that date bottling the bunches will be found to answer best for the welfare of the Vines. In the latter end of February this year, I cut two honses of late Grapes, consisting of the following varieties:—Black Alicante, Barbarossa, Royal Vineyard, and Lady Downe's Seedling, and they will be consumed in the order in which they are placed. They were all bottled, and the bottles tied to the wires of one of the late houses, where the temperature could be properly regulated, and the roof shaded on sunny days. Late ripened Grapes had a very bad season to contend with in 1872, and they are not so well coloured as usual, nor so good in their keeping properties, but yet I expect to have them in fair condition up till the end of May. WILLIAM TILLERY.

M. LALIMAN, of Bordeaux, is about to submit to the Académie at Paris the results of his investigations into the origin of the Phylloxera, which, he is convinced, has not been, according to the received opinion, introduced by means of imported American Vines. In a communication to a Portuguese journal, M. Laliman states that, as a wine-grower, all his hopes for the future rest on Vines grafted on the American species—*Vitis aestivalis*, *cordifolia*, and *vulpina*, which, he has found, are never attacked by the Phylloxera.

## NOTES OF THE WEEK.

— EXCEPT in the Hyacinth farms of the Dutch we suppose there is no place where so many Hyacinths may now be seen in flower as in Hyde Park in the strip of garden parallel with Park Lane.

— WE are informed that the fine Bougainvillea, at Greenlands, Henley-on-Thames, is now in great beauty, and if it is in anything like the condition in which it was when we saw it a year or two ago, it is well worth a visit.

— WE are indebted to M. Pynaert for the discovery that *Lilium auratum*, besides being a beautiful plant, is a grand specific against house-flies, and that a single specimen of it in an apartment will keep it clear of these troublesome insects.

— WE have had an opportunity of inspecting specimens of Cooling's Matchless Winter Broccoli, and feel satisfied that it is a valuable addition to vegetables in use at this season of the year. The heads, which are beautiful in form, are large, solid, remarkably white, and well protected by means of the leaves, which grow over the "flower," as in the case of Knight's Protecting Broccoli. When cooked the flavour is excellent; indeed, we have no hesitation in stating that, taking all its good qualities into account, it is one of the finest Broccolies in cultivation.

— THE Royal Winter Garden and ranges of greenhouses, figured in THE GARDEN, p. 103, vol. i, and erected at West Coates by Messrs. Downie, Laird, & Laing, were formally opened to the public last Saturday by the Lord Provost of Edinburgh, in presence of an immense concourse of spectators. A grand exhibition of spring-flowering plants was held in connection with the opening.

— THE prospects of the Bath meeting of the Royal Horticultural Society become now more encouraging every week. We find that the prizes to be awarded, instead of being £1,800, as first announced, will be £1,900, being £300 in excess of the amount distributed at Birmingham. The schedule of prizes is now ready for delivery by the secretary, and Mr. Eyles has likewise prepared a plan for the arrangement of the ground, and the position of the various tents.

— WITH reference to the appearance of the fruit crops, Mr. Gilbert, of Burghley, writes to us that both indoors and outside there is a want of vigour in the bloom-buds, more particularly in those of Peaches, Nectarines, and Apricots, all of which fail to show that boldness which is essentially necessary for a crop of good fruit, even in the orchard house. A good many of the Peach walls at Burghley are furnished with 3-foot wide glass copings; still, even under such circumstances, there is a want of robustness. Pears on west walls are, however, all that can be wished, as regards show of bloom; but Plums, particularly Green Gages, are deficient in that respect. The Cherry Plum for these five seasons past has been studded with bloom, but this year it is without blossom. Apples, however, look more promising, and so do Cherries and Figs; and the season being now far advanced, let us hope that no nipping frosts may blight our expectations.

— AT a special general meeting of the Royal Horticultural Society, held at South Kensington last Friday, the old Council, in accordance with the new bye-laws, tendered their resignations, which, with the exception of those of H.R.H. Prince Arthur, the Duke of Teck, the Duke of Buccleuch, and Lord Londesborough, were accepted. A new council was then elected, consisting of Viscount Bury, M.P., Hon. R. Chetwynd, Mr. Harcastle, M.P., Sir Coutts Lindsay, Mr. W. A. Lindsay, Sir A. Slade, Dr. Kellock, Mr. A. Smee, Mr. H. Little, and Mr. A. Murray. Sir Coutts Lindsay moved, and Viscount Bury seconded, the re-election of the Duke of Buccleuch as president. This was carried, as was also a resolution to the effect that, should his grace refuse to accept the post, Her Majesty should be asked graciously to nominate a president. Mr. W. A. Lindsay was elected secretary in the room of Major-General Scott.

— IN reference to the Veitch Memorial Prizes, we are enabled to state that, with the consent of the Council of the Royal Horticultural Society, the Trustees will distribute the following prizes at the forthcoming show of the Society at Bath, in June next: A. For the most meritorious dish of Black Grapes, exhibited as above. The Veitch Memorial Medal, and a prize of £5.—B. For the most meritorious dish of White Grapes (Muscats), exhibited as above. The Veitch Memorial Medal, and a prize of £5.—C. For the most meritorious dish of White Grapes (not Muscats), exhibited as above. The Veitch Memorial Medal, and a prize of £5.—D. For the most meritorious specimen Orchid in flower, exhibited as above. The Veitch Memorial Medal, and a prize of £5.—E. For the most meritorious specimen Stove Plant, in flower, exhibited as above. The Veitch Memorial Medal, and a prize of £5.—F. For the most meritorious specimen Greenhouse Plant, in flower, exhibited as above. The Veitch Memorial Medal, and a prize of £5. The subjects for the

foregoing prizes are to be selected from amongst the objects exhibited at the above-named show, in accordance with the Royal Horticultural Society's Prize Schedule, by *bona fide* gardeners of Great Britain or Ireland. A notification of entry on the part of those who desire to compete is to be sent, not later than June 11, to the Trustees, under cover to Mr. Moore, Botanic Garden, Chelsea, and it must be stated in which of the classes in the Society's and the Local Special Schedule of Prizes the exhibits will be found. The awards will be made for high-class cultivation, and the decisions of the judges will be final.

— THE ride which has for some time past been in course of construction round Batterssea Park is now completed, with the exception of about half a mile in length, the works from the York-road entrance on the south side westward having been finished within the last few weeks, and there will shortly be a continuous equestrian ride entirely round the park nearly two miles in length.

— TOWARDS the end of last month, Senor J. A. Henriques, director of the Botanic Gardens at Coimbra, visited Oporto for the purpose of making arrangements with one of the principal iron-founders of that city for the erection of a large stove in the gardens of the University. The new structure will be devoted to the growth of Ficus and other plants which require a moist warm atmosphere. It will stand close to the great Palm-houses, and will cover a space of nearly 1,900 square feet.

— AT a dinner recently given at Delmonico's, New York, the dining-room was filled on each side with banks of Moss brought on purpose from the south, in which masses of flowers of the choicest kinds were placed, including several hundred yellow Roses which cost one dollar each. Down the centre was a tank full of water, over which was an aviary of song birds, and in the midst two swans, real ones, swam about, the whole adorned with superb flowers, water Lilies, and Ferns. During the evening four ladies fainted from the overpowering effects of the flowers.

— AS a pleasing testimony to the progress of horticulture in distant parts of the world, we read in the current number of the Portuguese *Jornal de Horticultura Pratica* that a horticultural exhibition was held last year at Lima, in Peru, at which M. Jean Verschaffelt, of Ghent, obtained a gold medal and a prize of £100 for his collections of various plants, Conifers, Zamias, &c.; Messrs. E. H. Krelage and Son, of Haarlem, a silver medal for Hyacinths; and M. Robert Neumann, of Erfurt, a silver medal for his collection of seeds. Although these prizes have been carried off by European, and not by native, competitors, the mere fact that an exhibition of this kind has been inaugurated in Peru is a most gratifying proof of advancement, and of a desire for further improvement on the part of the inhabitants.

— THE prize list of the great International Horticultural Exhibition to be held in Manchester next September, a copy of which we have just received, seems to have been framed in a most liberal spirit. There are no fewer than seventy classes for fruit alone, twenty-seven for vegetables, twenty-three for cut flowers, seven for bouquets and table decorations, nineteen for plants, nine for implements and designs, and six for miscellaneous subjects. For the best collection of twenty kinds of fruits, including not more than two kinds of Grapes, two of Pine Apples, and two of Melons, a first prize of £30 is offered, a second one of £20, and a third of £12. For the best collection of fifteen kinds of fruit there is a first prize of £20, and another of £12 for the best group of ten kinds, exclusive of Pines. The following first prizes are also offered, viz., for twelve kinds of hardy fruits, £8; ten varieties of Grapes, £15; five varieties of Grapes, £7; three bunches of Black Hamburg, £5, and the same sum for similar exhibitions of Muscat of Alexandria, any other white Grape, and any other black Grape. For an ornamental basket of Grapes, consisting of not less than eight varieties, £10 are offered for the heaviest bunch of black and the same of white Grapes £3, and for the best seedling Grape not in commerce, £5. Prizes, on the same liberal scale, are likewise offered for Pines, Peaches, Nectarines, Apricots, Melons, Figs, Pears, Apples, &c. For fruiterers' collections several classes are open, the first prize in one, for a miscellaneous group, being £20. To France and Italy, Germany, the United States, British North America, and Turkey and Egypt, several classes are also assigned for fruits grown in these countries. The first prizes in the vegetable classes range from 10s. to £12, those in the section for cut flowers from 10s. to £7, and for bouquets, &c., from £1 10s. to £4. For six blooming and six fine foliaged plants a first prize of £20 is offered, and others vary from £3 to £10. For the implements, &c., medals only are offered. Altogether the prize list amounts to considerably over £1,000, in which are included several gold medals, valued at £7 7s. each; besides these, too, there are eleven medals to which no value has been assigned. Surely an undertaking on such a liberal scale cannot fail to meet with a hearty response.

## THE INDOOR GARDEN.

### STAG'S-HORN FERNS.

(PLATYCERIUMS.)

In a natural state these are epiphytal, therefore they succeed best and display their beauty to the greatest advantage when treated in that way. To do this properly, the blocks on which they are placed should be of large diameter, so as to prevent the fronds or shields, as they are sometimes called, clasping too tightly, and thus concealing a great portion of the beauty of the plant. They should also be of sound material, in order that they may last as long as possible; the dead stem of the Tree Fern I have found suits them admirably—*Dicksonia antarctica* being perhaps the best, because the stems of that species are much stouter than those of any other kind. I have also grown Stag's-horn Ferns in pots made especially for the purpose, *i.e.*, with half the side cut away, where it is compulsory to grow them in pots; this is undoubtedly a good contrivance, but I much prefer them on blocks of wood, so that they may be hung up in any portion of the fernery according to convenience or taste. *Platyceriums* are not by any means difficult to cultivate. When fastened upon the blocks with copper wire, some fresh sphagnum and fibrous peat should be packed down behind the barren fronds, and the plant and block immersed in water until the soil is thoroughly saturated; after this the only care necessary is to maintain a moist atmosphere, and to give sufficient water to keep the soil in a nice moist condition. The following kinds are in cultivation, and each of them having a character peculiarly its own, all of them may be grown in the same collection without producing a monotonous effect.

**P. ALCICORNE** (the Elk's Horn Fern).—This species, on account of its small barren fronds, and the rapid manner in which it throws out young plants from its roots, forms a fine object when planted in a basket. There is, however, a larger variety of it, in which the barren fronds stand more erect and are larger in size than those of the species itself, and which consequently shows to greater advantage on a block than in a basket. In the normal state, the sterile fronds are somewhat reniform, sessile, and persistent; the fertile ones stipitate, coriaceous, dichotomously forked, clothed with white stellate scales, and from 12 to 24 inches long; the sori are disposed in amorphous patches on the lobes at the extremities of the fronds. It thrives well either in stove or greenhouse, but grows more luxuriantly in the former than in the latter. It has a wide geographical range, being found in Java, the Malay Archipelago, Madagascar, and in various parts of Australia.

**P. GRANDE.**—This fine species, as already remarked, should be grown upon a large block, upon which it forms a beautiful coronet. The sterile fronds or shields are erect and permanent, alternately overlapping each other, rounded on the lower edge, the upper part much divided or forked. The fertile fronds rise from the sinus of the sterile ones, are coriaceous in texture, many times dichotomously forked, and densely clothed with white stellate scales. They measure from 1 to 3 feet in length, and the sori form a dense, irregular patch near the sinus of the

first division. It requires a stove temperature. It is a native of the Malay Islands and of various parts of Anstralia.

**P. STEMMARIA.**—This is a fine stove species from Western Africa. Its barren or sterile fronds are sessile, large, sub-ascending, and measure from 1 to 2 feet in height. Although permanent, these differ from those belonging to other species, inasmuch as they die annually, and change from glaucous green to chestnut brown. They are, however, hidden by the young shields, which are produced every spring. The fertile fronds are 2 to 3 times forked, thick and leathery in texture, the upper side dark green, but densely clothed on the lower side with white stellate scales; the sori are dark brown, situated on the under side of each lobe. Of this species the late Dr. Welwitsch discovered a singular form, with large spatulate fronds, in a locality far distant from that in which *P. Stemmaria* is found.

**P. BIFORME.**—This is a rare plant; indeed, I am not sure that the true species is really in cultivation. The plant which we have in our collections under this name has much the appearance of a narrow-leaved form of *Stemmaria*; but, as no large specimens have come under my notice, I cannot speak positively on this point.

The specimens which I have from Moulmein of the true plant show it to produce very long and pendulous narrow fertile fronds, which must have a splendid effect when seen growing in a suitable position; whilst the irregular-shaped masses of sori occupy a scutiform lobe separately. It requires stove heat, and exactly the same treatment as *P. grande*. It is a native of Burmah and various islands in the Indian Archipelago.

**P. WALLICHI.**—I have seen young plants under this name in a few collections, but they were far too small to enable me to decide whether or not they were anything but plants of *P. grande*. The true plant would appear to be of majestic appearance, the sterile fronds being much broader and longer than those of *P. grande*, which they otherwise much resemble, and also in being more forked; the fertile fronds are also larger and

more deeply divided, and densely clothed with white stellate scales. It will form a grand addition to the cultivated species of this small but extremely beautiful group of Ferns. It is a native of Borneo.

G.

*Platycerium grande.*

### CHRYSANTHEMUMS FOR THE CONSERVATORY.

BY ADAM FORSYTH, STOKES NEWINGTON.

IN the gloomy months of November and December, when the Chrysanthemum is in its prime, gaslight entertainments begin to assume increased importance, and many of these might be considerably enriched by the aid of these noble flowers. The Poinsettia and the Solanum are charming things for gaslight decoration, but the Chrysanthemum affords endless variety at an exceedingly cheap rate; and in a private entrance-hall, a concert-room, a bazaar, or the covered approaches to any place of public resort, a bank of Chrysanthemums affords a brilliant welcome and a grand accompaniment to any kind of festivity, because every known variety appears to advantage under gaslight. The employment of Chrysanthemums in decoration of the greenhouse and conservatory is most important, and I have endeavoured to exemplify the value of the plant for this purpose at my nurseries at Shackwell and Stokes Newington, during

many years past, and in that time I have seen many a garden made gloriously gay by the adoption of the plant for a conservatory feature. It should be remembered that it is not necessary to bestow so much care on specimens for home use as for a public exhibition. Provided they are leafy, healthy, flowery, bright, and bnxom, the requirements of the case are satisfied. They need not be trained at all; they may all be grown according to their natural characters, as bushes, and if the assortment consists of Pompones and large-flowering varieties in about equal proportions, they may be grouped so as to form a dense rich wall of flowers, well backed up by a groundwork of dark leafage. In preparing a display of autumnal flowers for the conservatory, it is well not to attempt too much, and it should consist chiefly of untrained plants. There is no particular necessity to begin business until March; by so doing, the cultivator is spared the trouble of nursing cuttings through the days of winter. Having the stools stowed away in a pit or under a wall, the cultivator will, early in March, take as many cuttings as he requires, and soon make nice plants of them. If he has no stock to begin with, he will, of course, have to beg or buy. In begging, it is well to make sure that you obtain cuttings worth having, with their proper names attached; for it is not at all unusual to find that a season has been wasted in growing sorts that have long since been discarded by good judges as unworthy of a place in any selection, unless it be a selection of sorts to be extinguished. It will be well to stop all the plants early in April, and a fortnight or so afterwards to shift them into forty-eight sized pots. About the middle of May they should all be put out and plunged. Very many amateurs who do the Chrysanthemum well do not plunge the pots. To them I say, long experience and observation—having the interest of my business to make me watchful—have convinced me that those who do well without plunging may do better with it, and they will escape many risks which plants in unplunged pots are always exposed to. As to any further stopping, a little judgment must be exercised. Look over the plants in the first week of June, and then and there settle that part of the business. If you are not familiar with the sorts, take a trade catalogue and look them through. When you find by the label on your plant that you have to decide as to one of the finest incurved varieties, do not stop the plant. In any case, if you find the variety is *not* recommended for specimen culture, refrain from stopping. On the other hand, those which *are* recommended for specimens may be stopped in the first week of June, as being free to flower. You will be safe, and will obtain more flowers than if you refrain from stopping. To sum up the case in a few broad rules. First-class incurved and late-flowering varieties should only be stopped once, and better if not stopped at all. Reflexed, free-flowering, and early-flowering kinds in all classes may be stopped twice, and the smaller sorts, such as Intermediates and Pompones, may be stopped three times, and the last pinching should be done in the early part of June or by the middle of June at latest.

One good reason for looking over the plants in the first week of June, and then making an end of the pinching business, is that about the middle of June the plants should be shifted into eight-inch pots, to give them a good chance in the height of the growing season. Keep them freely watered at the root, and overhead in dry weather, and even in rainy weather see that they are moist enough at the root, for it often happens that, while the leaves are well washed by rain, the roots get none of it. By the middle of July it will be necessary to settle another point—which are to be shifted and which are not. Here, again, the sorts may be classified very nearly as above; but the first thing to consider is the size and general appearance of the plants. The first-class show kinds will be the better for a shift into eleven-inch pots, where large specimens are required, but the reflexed and smaller kinds may be allowed to flower in eight-inch pots, and may be helped to the end of their journey by liquid manure as soon as they have quite filled their pots with roots. In any case, however, robust plants that have quite filled their pots with roots, and that appear, by their ample leafage and stout stems, to be capable of growing considerably larger yet, should be shifted to give them a chance of making a grand show when their day of triumph arrives. The question will arise in the ambitious mind—why stop at eleven-inch pots? why not go on far beyond that? The proper reply, perhaps, would be, that experience has proved that to overpot these plants is to waste labour, and render them unwieldy without the slightest gain, but probably a loss both in quantity and quality of flower. The growing season extends from about the 1st of March to the 1st of August—say, to put it roughly, six months. In that time the plant will attain to a certain size, according to its advantages, and it is the business of the cultivator to provide all the advantages the plant can make use of. But when the growing season ends, the wood begins to ripen, and the flower-buds to swell, and the increase of root-room then is more harm than good. In case of

any large vase or basket or tub requiring to be filled with Chrysanthemums, the best way would be to plant it with a lot of healthy plants out of forty-eight sized pots about the middle of May, taking care not to overcrowd them, and to keep them nicely tied out, to prevent destruction of the lower leaves by overlapping.

In preparing a conservatory display, the greatest care should be taken to keep the plants green to the bottom. In growing for cut flowers this is of less importance, although it is not unimportant. In selecting for conservatory decoration, free-flowering kinds of the most distinct and striking colours are always to be preferred. Many of the most perfect exhibition incurved flowers are not showy, and, although a connoisseur will prefer them to all others, many of the high coloured reflexed flowers will be preferred by those who are less critical. Plenty of flowers and plenty of colour are the principal desiderata in selecting for conservatory decoration, and happily there are a few of the very finest exhibition kinds, such, for example, as Jardin des Plantes, Mrs. G. Rundle, Dr. Sharp, and the Prince of Wales, which give us an abundance of flowers, of the most attractive character. It is not important to select early-blooming kinds, because they will have the aid of glass after the first or second week in October, and be safe from the destruction of their opening buds by frost.—*Floral World*.

**Acrid Properties of Dieffenbachias.**—All the species of Dieffenbachia in cultivation are natives of tropical South America and the West Indian Islands, where they grow in moist shady woods, and frequently form stems from 8 to 10 feet in length, and sometimes even more. These snake-like stems becoming too weak for self-support assume a recumbent position, and if bent into the earth root at every joint. The juices of Dieffenbachias are so excessively acrid that if a piece of the root or stem be taken into the mouth and slightly compressed, it affects the person who tastes it in a serious manner, the tongue becoming so swollen as to be scarcely containable in the mouth. D. Seguinia possesses this dangerous property to such an extent that it is known in its native country by the name of Dumb Cane. Other species of this genus too inherit similar properties; for a young gardener with whom I was acquainted being induced to taste a piece of the stem of D. Baraquiniana was badly affected by it; others I know are also extremely acrid, as I can testify from my own experience, having several times just touched with the tip of my tongue newly cut pieces of stem, and found them most disagreeable, in short, ten times more unpalatable than Gentian root.—W. FORBES.

**Balsams.**—When well grown these are, perhaps, the showiest of all our tender annuals, and are those best adapted for conservatory decoration from July to September. They like all the light our climate affords, and a rich, open compost to grow in; the great demand made on the roots during the period of active growth informs us, too, that liquid manure is a useful auxiliary to keep up vigour, and may be applied freely when the pots become full of roots; bottom heat must also be given while they are growing, and they like plenty of air during every stage of growth. The soil preferred is half-decayed turf, calcined clayey loam, horse droppings, half rotten, and rubbed through a half-inch sieve, and bone-dust. The clayey loam I calcine sufficiently, and it acts as a drainage to the soil; in the absence of this, soft bricks broken to the size of Filberts may be used. The turfy loam may comprise rather over one-half the mixture, the dung and drainage material the other. A handful or two of bone-dust may be used or not, as it may be at hand. The seed should be sown in pans in a hotbed, and the young plants potted singly as soon as they are an inch above-ground, otherwise they become unshapely and drawn. Each time the plants are shifted, lower the ball a little in the pots, so that the stems may be short, and that roots may be produced from the parts buried. If possible, keep them plunged in bottom heat, but near the glass, in a frame, the shades of which are tilted up a little night and day. Should they form flower-buds sooner than wanted, rub them off, and they will speedily be succeeded by another supply.—F. S.

#### NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**New Holland Pitcher-Plant (Cephalotus follicularis).**—I have failed with this plant, and should be glad of a few words of advice as to its culture. B. [Grow it on a shelf near the glass in a mixture of sphagnum and peat and keep it moist throughout the growing season.]

**Hoteia (Spirea) japonica.**—This, although quite hardy, is an excellent plant for forcing. Its lively green foliage and charming white flowers make it extremely useful in all kinds of ways, and the demand for it for bouquet work, as well as for furnishing purposes, is very great. It is easily grown, and no establishment should be without it.—F.

## THE FLOWER GARDEN.

## RAMONDIA PYRENAICA.

This interesting Pyrenean plant is found on steep, somewhat shady rocks, and, according to Ramond, exclusively in valleys leading from north to south; its leaves are in rosettes spreading very close to the ground, blistered, deeply wrinkled, and densely covered with short hairs, which are quite shaggy beneath and on the leaf-stalk. The flowers, which are purple-violet, with orange-yellow centre, and from an inch to an inch and a half across, are borne on stems from 2 to 6 inches long. It does very well on rockwork in mossy fissures filled with well-drained peaty earth, and is easily grown in cold frames in well-drained pots, well watered during the warm months. It is increased by means of seed with the greatest facility, and is well worthy of general culture. It is usually seen in gardens with only two or three sprays of flower; but in a window of the dining-room at Benthall Hall, we had the pleasure of seeing a specimen of it last year nearly a foot in diameter, and with quite a little cloud of large soft mauve flowers. The plant had been grown in a cool frame all through the winter and spring; it, however, does well in the open border. The largest pot specimens at Benthall were formed by putting a number of young suckers in a pot.

## HERBACEOUS PHLOXES.

THERE are two distinct types of herbaceous Phloxes in cultivation, viz., the *P. suffruticosa* or shrubby section, and the *P. decussata* section, which embraces garden hybrids having a more robust growth, and being rather later in coming into flower than the others. The varieties of the former section (*suffruticosa*) are largely cultivated in Scotland and in the moister districts of the midland counties and north of England; but in the neighbourhood of London and in the home and southern counties they are scarcely grown at all, as they do not do well. A cool moist climate suits the *suffruticosa* section best; but the varieties of *P. decussata* appear adapted for general cultivation, and are seen everywhere. The varieties of both sections are readily propagated by division of the roots in spring, and also by means of cuttings taken from the young growth which appears round the base of the flowering stem during the summer. The cuttings root quickly when placed in light sandy soil in a frame or cool house, and covered with a hand-glass. As soon as rooted, the plants should be placed singly in large thumb or small 60 pots, and be wintered in a cold frame, where they can be kept close during severe weather. In spring they can be transferred to a bed formed of deep, rich, strong loam and leaf soil, as the panicles, or the trusses of flowers, as they are sometimes termed, come much more finely developed than when grown in a light, free, and dry soil. In the southern districts of England, and in fact in the majority of places in northern localities, the Phlox can be wintered in the open ground with little fear of injury; but it is always better to protect the crowns of the choicer varieties in some way, either with a covering of ashes or some loose litter shaken over them. A bed of Phloxes planted on a piece of well-prepared ground is an object of great beauty in a garden, and also of value for furnishing cut flowers. The cultivation of the Phlox in pots is by no means difficult; but to do it successfully requires some knowledge of the varieties that succeed best in this way. The cultivator who first essays this mode of treatment should select the strongest of the newly-struck cuttings, and shift them into 48-pots, and subsequently into 32-pots if required. At the end of April these should be placed in the blooming pots, which ought to be from 8 inches to 10 inches in diameter; and after potting is done the pots should be plunged in ashes, tan, or any other suitable material, in a shady position, and on no account be allowed to suffer for want of water. A check at this

stage would result in grave consequences to the plants. When the plants come into bloom they may be removed to the conservatory, and be kept well watered. As soon as the plants have ripened their growth after blooming, they should be cut down, and the pots plunged in ashes in the open ground; and, when severe weather comes, some litter should be shaken over the crowns to keep them from being harmed by frost. Here they can remain till spring, and when they begin to start into growth the plants should be turned out of the blooming pots, the roots trimmed, and then placed in smaller pots; and, as soon as these become filled with roots, be again placed in the pots in which they are to flower, and be treated as before directed. New varieties of perennial Phloxes are obtained from seeds; but so much difficulty has been experienced in getting the seed to germinate, that many are deterred from attempting to raise seedlings for themselves. Frequent failures have resulted from attempting to raise them in heat. R. D.

## NEW, RARE, OR NEGLECTED ALPINE PLANTS.

BY J. C. NIVEN, BOTANIC GARDENS, HULL.

(Continued from p. 257.)

*SEMPERVIVUM ARENARIUM*, when grown in dense patches, has a lovely effect. It is much smaller than *S. globiferum*, to which it is allied, and is usually of a richly crimson colour; the leaves in the rosettes are not incurved, as in the latter species; the flowers are small, but crimson, and exceedingly pretty.

*S. ANOMALUM*.—A native of Dauphiny, in the South of France; the rosettes are small, and covered with glandular hairs; as regards blossom, it is one of the prettiest species, is perfectly hardy, and of as free growth as our own common Houseleek.

*S. HEUFFELI* is remarkable for the rich tints its foliage assumes in the autumn—almost a chocolate crimson. It is very distinct in the form of its flowers from all other species, its flowers being more tubular, and not expanded; they are of a

yellow colour, and, as regards the value of the plant in point of beauty, may be readily dispensed with.

*S. HIRTUM*, *PILIFERUM*, and *FIMBRIATUM* are all remarkable for possessing little dense tassels of hair at the extremity of each leaf; they are closely allied to one another, though bearing distinctive characters, not, perhaps, noticeable to the casual observer.

*S. PITTONI*.—A somewhat tender-looking plant, but, nevertheless, perfectly hardy; it is a very distinct species, the leaves being covered with fleshy hairs that give the whole plant the appearance of being frosted over.

*S. REGINE AMALÆ*.—A fine vigorous grower, from Greece; scarce yet in cultivation, and likely to remain so for some time, on account of its slightly arborescent character.

*SILENE QUADRIFIDA* and *QUADRIDENTATA* are species that deserve more than mere nominal mention; in fact, among the dwarf rock plants they have scarcely any equals. *Quadrifida* has narrow leaves, grows about 4 inches high, producing two or three flowers on each stem, of pure white, and beautifully notched. *S. quadridentata* grows about 2 inches high, and for at least a month is covered with its small but exquisitely symmetrical white blossoms. They are both perfectly hardy when given a suitable locality on a rockwork, and will be found well worthy of that distinction.

*STATICE MINUTA*, *BELLIDIFOLIA*, *NANA*, and *SPECIOSA* are all species well worthy of cultivation, compact in habit, the flowers produced freely and of long continuance, added to which they

Ramondia pyrenaica.

are on a dry subsoil perfectly hardy. There are no flowers better adapted, in lightness and elegance, for giving a sort of neutral tint finish to a bouquet of flowers.

**TEUCRIUM PYRENAICUM.**—A dwarf alpine plant with roundish leaves, somewhat woolly, and producing an abundance of sober-coloured flowers. It is well worthy of a place in all collections.

**THALICTRUM TUBEROSUM.**—Grows about 9 inches high. Besides the usually graceful foliage which we find in all the dwarf forms of the genus *Thalictrum*, we have in this instance an additional beauty in the abundant mass of yellowish cream-coloured flowers which this plant produces. It is perfectly hardy, and thrives in a deep peat soil.

**THYMUS SERPYLLUM ALBUM**, the white variety of our common wild Thyme is a lovely plant for a sunny bank. Nothing can be more charming than such a bank covered with a mixture of the common wild form and the white variety. Singularly enough, I have never met with the white variety wild. The first plant that I cultivated came from the Carpathian Mountains, and, if I mistake not, the said plant is the parent of all now in cultivation.

**TROLLIUS.**—This genus, although more generally grown as a border plant, is a true alpine. Who, in rambling in the fields that border, as it were, the altitudinal zone of cultivation, has not been struck with the great contrast produced between the golden colour of the Buttercups, or still more golden of the Marsh Marigold (*Caltha palustris*) and the delicate lemon tint of our own *Trollius europæus*? And how many beautiful congeners has this *Trollius europæus*, ranging from *T. pumilus pallidus* (sometimes called *albus*), to the noble border plant *T. napellifolius*, with its large orange blossoms, almost the size of oranges; the former some 9 inches high, with cream-coloured flowers, the latter when growing vigorously full 30 in. high. Especially noticeable in this group are *T. sinensis*, in which the modified linear petals are exerted, and form a sort of rigid crown of intense gold, rising from amid the expanded petals; and *T. americanus*, rarely to be met with true, but when obtained to be cherished. Its petals almost approach the scarlet tint along their outer margin.

**VERONICA SATUREIFOLIA** is one of the very finest species; the flowers are about the size of *V. saxatilis*, of the same intense blue, and produced in abundant upright racemes. A somewhat rare plant, but, when once seen growing in perfection, never to be forgotten. Add *Veronica lactea* syn. *repens*, *verbenacea*, *pectinata*, *rupestris*, *bellidifolia*, *Daubeneyi*, all species well worth cultivation, of good dwarf habit, and admirably adapted for rockery. Nor should the pink variety of *V. officinalis* be omitted—forming, as it does when established, dense patches of pink-coloured blossoms, some elevated 3 inches above the surface of the ground.

(To be continued.)

**Destruction of Crocus Roots.**—I send you some roots from a long, broad border, in which there has been a broad band of common yellow Crocuses for upwards of twenty years. During the last two or three years they have failed at one end, at first only two or three yards; last year about six, and this year the disease seems to have spread about two yards further still. Both last year and the year before the vacancy was filled up by strong bulbs from Holland, which came up well, but went off as you will see by the bulbs sent. They are all covered with a small white insect, rather like a miniature woodlouse. I shall, therefore, be very grateful if you can tell me the name, cause, and cure for this insect, as it sadly spoils the effect of the border, which is about eighty yards long. Blue *Salvias* have also gone off mysteriously in the same border.—F. M. [The insect or grub was crushed in transit, but we believe it to be one of the *Myriapoda* named *Polydesmus complanatus*. We do not think, however, that it is the author of the mischief, which we attribute to mice, the marks of their rodent teeth appearing on one of the bulbs.]

**Bignonia capreolata.**—This *Bignonia*, described at p. 61, is perfectly hardy with me.—H. N. ELLACOMBE, *Bilton Vicarage, Gloucestershire*.

**Primula nivalis.**—This, which is sometimes called *helvetica*, is one of the most beautiful of pure white spring flowers. Its leaves are very much serrated, and the truss of bloom is close to the foliage, each plant forming a bouquet in itself. It is now everywhere in fine bloom.—R. H. B.

## THE ARBORETUM.

### THE MOVEMENT OF THE SAP.

THE correspondence which you have hitherto published on this subject tends to show that sap does not descend; but let us take, for example, a *Pelargonium* cutting. How does it happen that, immediately it is placed in conditions favourable to growth, it emits roots? Does not this prove that the old notion—viz., that the sap ascends, is changed in the leaves, and comes down in the shape of organisable matter—is true? Roots themselves, even, only increase when acted on by this descending sap. It has been said that every particle of descending sap is assimilated by different organs previously formed, and that nothing remains in the stem but wood at the fall of the leaf. In opposition to this statement let me cite a case or two. If a tree planted in the open air have one of its branches conveyed to the inside of a house in which there is a high temperature, even in the dead of winter, when the stem and other parts outside are dormant, the branch thus introduced to heat will immediately start into growth. Therefore, if no particle of sap remains, but if, on the contrary, all is assimilated or converted into wood in autumn, how does it happen that the sap begins to flow, and that leaf-buds and flower-buds begin to open? Is the woolly portion soluble, and capable of being again reduced to sap, or cambium, by means of heat? No. As much organisable matter remains in plants during their period of rest as serves to start them again in spring. Why, if nothing remained in such cuttings as those of Gooseberries and Currants but wood, we might as well put walking-sticks in the ground in spring and expect them to strike root. We all know that in winter there is a strong tendency to sleep, both in the animal and vegetable kingdoms. The little dormouse goes to sleep at the approach of winter, and remains in a torpid condition until warm weather comes; and then, affected by its influence, awakes from its insensibility and partakes of some food. But, should that warm period be followed by cold, it will again go to sleep until the advent of summer weather finally rouses it into activity. Now, if there had not been blood in the veins of this little sleeper, ready to be set in motion under the influence of warmth, it would have slept on; and, as far as my opinion leads me to believe, plants destitute of sap or cambium will never start into growth. I, therefore, conclude that there is a descent of the sap, and that it is on that account that cuttings root and that wood is formed. How do your correspondents account for the fact that, in all cases in which a limb is removed from a tree, the wood-forming matter of the cicatrix comes from above, and never from below?

*Kew.*

J. BRENNAN.

### ENCOURAGEMENT TO PLANTERS.

WE learn from one of the editors of the *New York Tribune* that a bill more important to settlers on the public lands of the United States than any that has before passed since the Homestead Act became law during the last hours of the session of Congress just closed. It is an Act to encourage the growth of timber on western prairies, and is the first measure of the kind that has ever been adopted by Congress. The following is its full text:—

Be it enacted, That any person who shall plant, protect, and keep in a healthy growing condition for five years, 40 acres of timber, the trees thereon not being more than 8 feet apart each way, on any quarter-section of any of the public lands of the United States, shall be entitled to a patent for the whole of said quarter-section at the expiration of said five years, on making proof of such fact by not less than two credible witnesses; provided, that only one quarter in any section shall be thus granted.

SEC. 2. That the person applying for the benefit of this act shall, upon application to the Register of the Land Office in which he or she is about to make such entry, make affidavit before said register or receiver that said entry is made for the cultivation of timber, and upon filing said affidavit with said register or receiver, and on payment of ten dollars, he or she shall thereupon be permitted to enter the quantity of land specified: Provided, however, That no certificate shall be given or patent issue therefore until the expiration of at least five years from the date of such entry; and if at the expiration of such time, or at any time within three years thereafter, the person making such entry, or if he or she be dead, his or her heirs or legal representatives, shall prove by two credible witnesses, that he, she, or they have planted, and for not less than five years have cultivated and protected such quantity and character of timber as aforesaid, they shall receive the patent for such quarter-section of land.

SEC. 3. That if, at any time after the filing of said affidavit, and prior to the issuing of the patent for said land, it shall be proven, after due notice to the party making such entry and claiming to cultivate such timber, to the satisfaction of the Register of the Land Office, that such person has abandoned or failed to cultivate, protect, and keep in good condition such timber, then, and in that event, said land shall revert to the United States.

## QUERCUS LOBATA.

THE group of Oaks here represented of the Californian white Oak (*Quercus lobata*) was sketched from nature in the vicinity of the well-known Oak Knoll Farm, Napa Valley. This is a good representative of the species which prevails in the plains of Central California, and in some of the northern valleys, but particularly in Scott's Valley, near Clear Lake, where, increasing in height, it assumes the character of a stately forest. Tall, straight, and attaining an elevation of 60 feet in stem before branching off, this Oak, frequently alternating with the Livi Oak (*Q. agrifolia*), imparts to the scenery of Central California near the coast range the prairie and park-like appearance which forms its principal charm. Our engraving of this is from a sketch kindly supplied by Mr. Edward Vischer, of San Francisco, a gentleman thoroughly conversant with Californian scenery and Californian trees, and whom

Pure woody fibre by itself is only very slightly affected by the destructive influences of wind and weather. When we observe that wood decays, that decay arises from the presence of substances in the wood which are foreign to the woody fibre, but are present in the juices of the wood while growing, and consist chiefly of albuminous matter which, when beginning to decay, also causes the destruction of the other constituents of the wood; but these changes occur in various kinds of wood only after a shorter or longer lapse of time; indeed, wood may in some instances last for several centuries and remain thoroughly sound; thus, the roof of Westminster Hall was built about 1090. Since resinous woods resist the action of damp and moisture for a long time, they generally last a considerable time; next in respect of durability follow such kinds of wood as are very hard and compact, and contain at the same time some substance which—like tannic acid—to some extent counteracts decay. The behaviour of the several woods under water differs greatly. Some woods are after a time con-

Quercus lobata.

we have to thank for a number of masterly sketches of the most remarkable aspects of vegetation in California.

## THE PRESERVATION OF WOOD.

## ON THE DURABILITY OF WOOD IN GENERAL.

THE durability of wood—viz., its power of resisting the destructive influences of wind and weather—varies greatly, and depends as much upon the particular kind of wood and the influences to which it is exposed as upon the origin of the wood (timber), its age at the time of felling, and other conditions. Beech wood and Oak placed permanently under water may last for centuries. Alder wood lasts only a short time when in a dry situation: but, when kept under water, it is a very lasting and substantial wood. Taking into consideration the different kinds and varying properties of wood, and the different uses to which it is applied, we have to consider, as regards its durability, the following particulars:—1. Whether it is more liable to decay by exposure to open air or when placed in damp situations. 2. Whether it is, when left dry, more or less attacked by the ravages of insects which, while in a state of larvæ, live in and on wood.

Other kinds of wood, again, undergo no change at all while under water—as, for instance, Oak, Alder, and Fir. Insects chiefly attack dry wood only. Splint wood is more liable to such attack than hard wood; while splint of oak wood is rather readily attacked by insects, the hard wood (inner or fully developed wood) is seldom so affected. Elm, Aspen, and all resinous woods are very seldom attacked by insects. Young wood, which is full of sap and left with the bark on, soon becomes quite worm-eaten, especially so the Alder, Birch, Willow, and Beech. The longer or shorter duration of wood depends more or less upon the following:—*a.* The conditions of growth. Wood from cold climates is generally more durable than that grown in warm climes. A poor soil produces as a rule a more durable and compact wood than does a soil rich in humus, and therefore containing also much moisture. *b.* The conditions in which the wood is placed greatly influence its duration. The warmer and moister the climate the more rapidly decomposition sets in; while a dry, cold climate materially aids the preservation of wood. *c.* The time of felling is of importance: wood cut down in winter is considered more durable than that felled in summer. In many countries the forest laws enjoin the felling of trees only between November 15th and February 15th. Wood employed for building, and not exposed to heat or moisture, is only likely to suffer from the

ravages of insects; but if it is placed so that no draught of fresh air can reach it, to prevent accumulation of products of decomposition, decay soon sets in, and the decaying albuminous substances acting upon the fibre cause it to lose its tenacity and become a friable mass. Under the influence of moisture fungi are developed upon the surface of the wood. These fungi are severally known as the "horse fungi" (*Thelephora domestica* and *Boletus destructor*), and the clinging fungus (*Merulius vastator*). They spread over the wood in a manner very similar to the growth of common fungi on soil. Their growth is greatly aided by moisture and by exclusion of light and fresh air. A chemical means of preventing such growths is found in the application to the wood of acetate of oxide of iron, the acetate being prepared from wood vinegar. Wood is often more injuriously affected when exposed to sea water, when it is attacked by a peculiar kind of insect known as the bore worm (*Teredo navalis*). This insect is armed with a horned beak capable of piercing the hardest wood to a depth of 36 centimetres. These insects originally belonged to and abound in great number in the seas under the tropical clime; but the *Teredo navalis* is met with on the coasts of Holland and England.

#### PRESERVATION OF WOOD IN PARTICULAR.

The means usually adopted to prevent the destruction of wood by decay are the following:—1. The elimination, as much as possible, of the water from the wood previously to its being employed. 2. The elimination of the constituents of the sap. 3. By keeping up a good circulation of air near the wood, so as to prevent its suffocation, as it is termed. 4. By chemical alteration of the constituents of the sap. 5. By the gradual mineralisation of the wood, and thus the elimination of the organic matter.

#### DRYING WOOD.

1. Thoroughly dried wood remains for a long time unaltered while in a dry situation, more especially so when dried by so strong a heat that it becomes browned. When timber has to be put into a damp situation, it should, after having been well dried, be first coated with a suitable substance, to prevent the moisture penetrating into the wood. This purpose is attained by coating the wood with linseed oil, so-called Stockholm tar, coal tar, creosote, and other hydrocarbons. Hutin and Boutigny adopt the following method to prevent the absorption of moisture by wood that is put into the ground. The portion of the post or wood to be buried is first immersed in a vessel containing benzol, petroleum, photogen, &c., and when taken out is ignited and thus charred. When extinguished, the wood is put to a depth of from 3 to 6 centimetres into a mixture of pitch, tar, and asphalt, and next the entire piece of wood is thoroughly painted over with tar.

#### ELIMINATION OF THE CONSTITUENTS OF THE SAP.

2. The constituents of the sap are the chief cause of the decomposition of wood, and they should consequently be removed. Many plans are adopted. In order that the wood may contain the smallest quantity of sap, it should be felled during the winter months. The constituents of the sap can be eliminated from the felled tree by three methods:—*a.* By treatment with cold water, with which the wood must be thoroughly saturated, to dissolve the constituents of the sap, which are removed when the wood is exposed to a stream of water. It is evident that with large timber a long time is necessary to ensure perfect saturation. *b.* By employing boiling water the sap is removed much more quickly and efficiently. The pieces of wood are placed in an iron vessel with water and boiled. Large pieces of timber cannot be treated in this manner, but are immersed in a cistern in which the fluid is heated by means of steam. According to the thickness of the wood, the boiling occupies some six to twelve hours. *c.* By treatment with steam (steaming of wood)—the most effectual method of removing the constituents of the sap, the hygroscopicity of the wood thus treated being rendered much less, while the wood is far more fitted to resist the effects of the weather. The apparatus employed in carrying out the method consists of a boiler for the generation of steam, and a cistern or steam chamber for the reception of the wood, this chamber being constructed of masonry and cement, of boiler plate, or being simply a large and very wide iron pipe. In most cases a jet of steam is conveyed from the boiler to the steam-chamber, where it penetrates the wood, and dissolves out the constituents of the sap, which, on being condensed, is allowed to run off. In the case of Oak, this fluid is of a black-brown colour; with mahogany, a brown-red; with linden wood, a red-yellow; and with Cherry tree wood, a red, &c. The operation is finished when the outflowing water is no more coloured. The steamed wood is dried in the air or in a drying room; it loses 5 to 10 per cent. in weight by the process, and becomes of a much darker colour. The steam is sometimes worked at a temperature of above 100°, but generally the contents of the steam chamber are maintained at 60° to 70°. Towards the end of the operation some oil of coal-tar is introduced into the boiler, and is consequently carried

over with the steam, impregnating the wood. The removal of the sap can also be effected to some extent by means of mechanical pressure between a pair of iron rollers, which are gradually brought more closely together. Another method is by means of air pressure. Barlow employs for this purpose a metal case in which the wood is enclosed, and to one end of which an air-pump is attached. Air being forced into the tube or case, the sap flows away at the end opposite to which the pump is attached. But both these methods are costly and not in all cases applicable.

#### AIR DRAINS.

3. The construction of air drains or passages around woodwork to be preserved is, where the method is applicable, a great aid to the preservation of the wood. The consideration of the best means of effecting ventilation in this respect, is not a matter with which we can deal in this work. It is sufficient to say, that in many instances the air channels are connected on the one hand with the open air, and on the other with the chimney.

#### CHEMICAL ALTERATIONS OF THE CONSTITUENTS OF THE SAP.

4. One of the most useful and most effective means of preventing the decomposition of wood is by effecting a chemical change in the constituents of the sap, so that fermentation can no longer be set up. To this class belongs the well-known plan of protecting woodwork that is to be exposed to the action of the moisture of the earth by charring the wood, either by fire or by treatment with concentrated sulphuric acid, so that the wood is coated to a certain depth with a layer of charcoal, the charcoal acting as an antiseptic. The charring or carbonisation of the wood can be effected either with the help of a gas flame or the flame from a coal fire. The apparatus of De Laparent, invented for this purpose, became very generally employed in 1866 at the dockyards of Cherbourg, Pola, and Dantzic. According to another method the wood is impregnated throughout its whole mass with some substance that either enters into combination with the constituents of the sap, or so alters their properties as to prevent the setting up of decomposition. To this class belong the four following methods, these being the only ones that have met with any more extensive use.

1. Kyan's preserving fluid is a solution of bichloride of mercury of variable degree of concentration. In England a solution of 1 kilo. of corrosive sublimate in 80 to 100 litres of water is generally employed for railway sleepers. The timber is laid in a watertight wooden trough, containing the solution, where, according to its size, it remains a longer or shorter time. In Baden the wood remains in the kyanising solution, when it is to be impregnated to a depth of—

82 m.m. for 4 days	180 to 240 m.m. for 14 days.
85 to 150 " 7 "	210 to 300 " 18 "
150 to 180 " 10 "	

the solution consisting of 1 kilo. of sublimate to 200 litres of water. The prepared wood is washed with water, rubbed dry, and then placed in sheds free from exposure to rain and strong sunlight. The principal action of the bichloride of mercury is to convert the albumen of the sap into an insoluble combination, capable of withstanding decomposition, while the bichloride becomes gradually reduced to protochloride of mercury (calomel). A great objection to this method is the danger to which the carpenter or joiner who may afterwards shape the wood is exposed, the free chemicals acting upon his system through his hands, nostrils, and mouth. In England wood to be varnished is seldom kyanised. Erdmann remarks upon this plan of preserving wood that the interior of the log is still left in its original condition. To answer the objection, the kyanising has been made more effective by placing the wood into a water-tight trough, with the solution of sublimate, and by a great pressure of air thoroughly impregnating the wood. Kyanising by this method becomes, however, as expensive as any other impregnation method. Recently there has been substituted for the pure bichloride of mercury a double salt of the formula  $HgCl_2$  to  $KCl$ , obtained by decomposing a solution of carnallite with oxide of mercury.

2. Burnett's patent (1810) fluid consists of 1 kilo. of chloride of zinc dissolved in 90 litres of waters. Wood treated with Burnett's fluid has been buried in earth for five years without undergoing any change, while unprepared wood buried for the same length of time has been totally destroyed. Chloride of zinc has been much used in Germany as an impregnating material. Besides this salt sulphate of copper and acetate of oxide of zinc—pyrolignite of zinc (Scheden's method), have been employed. The action of the copper and zinc salts may be explained by considering that the metallic oxides of the basic salt formed during seasoning, separate and combine with the colouring matter, tannic acid, resin, &c. of the wood, to form an insoluble compound.

3. Bethel's (1838) patented method consists in treatment under strong pressure with a mixture of tar, oil of tar, and carbolic acid, this mixture being known commercially by the name of gallotin. In

and near London, wood thus treated has remained eleven years in the earth without undergoing change; other pieces of timber so treated were subjected to the action of the sea for four years and still were in good condition. Vohl employs for preservation peat and brown coal creosote; Leuchs uses paraffin. Such agents, however, render wood treated with them highly inflammable.

4. Payne's method. This includes two patents, the first having been taken out in 1841. Both are based on the impregnation of the wood—first with one salt, and next with another salt, which is capable of forming a precipitate insoluble in water and sap of the wood with the first. The first solution is usually one of sulphate of iron or of alum, then follows a solution of chloride of calcium or of soda. The wood to be impregnated is placed in a vessel from which the air is exhausted, the first solution being then admitted, and subsequently pressure is applied. The first solution being removed, the second is admitted, and pressure again applied. It is necessary to dry the wood partially between the two impregnations. Payne's method, much used in England, possesses, moreover, the advantage of rendering the wood somewhat non-inflammable. The same effect results with the methods of Buehner and Von Eichthal, who impregnate the wood with a solution of sulphate of iron, and then with a water-glass solution, whereby the pores of the wood are filled with ferro-silicate. Ransome attains the same end by an impregnation with a water-glass solution and subsequent treatment with an acid. It is found that the treatment of wood according to the above methods is generally attended with good results. A method of impregnation with materials forming an insoluble soap, oleate of alumina, oleate of copper, &c., patented in 1862, has given some moderate results on a small scale.

#### MINERALISING WOOD.

5. When the terms mineralised, petrified, metalised, or incrustated are applied to wood, they include the meaning that the wood has undergone impregnation with an inorganic substance, which has so filled the pores of the wood that it may be said to partake of the characteristics of a mineral substance. Suppose that the wood has become impregnated with sulphate of iron, when exposed to the rain the sulphate will be gradually dissolved out, in time leaving only a basic sulphate. By the researches of Strützi (1834), of Apelt in Jena, and of Kuhlmann (1859), the influence of oxide of iron upon wood fibre has been rendered very clear. Wood impregnated with basic sulphate of iron ceases to be wood after some time.

#### BOUCHERIE'S METHOD OF IMPREGNATION.

6. This method consists in the impregnation of the wood with the necessary substance, in a manner similar to the natural filling of the pores with sap; that is to say, the solution is introduced into the tree from its roots, and is thus made to take the place of the sap in all parts of the timber. When the tree is felled the root end is placed in a solution of the salt (sulphate of copper, acetate of iron), and allowed to remain for some days; at the end of the required time the wood will have become completely impregnated with the salt. Occasionally this method is employed in colouring woods, colouring matter being used instead of, or as well as, the salt. The Linden, Beech, Willow, Elm, Alder, and Pear tree can be treated in this manner. The Fir, Oak, Ash, Poplar, and Cherry tree do not, however, absorb the impregnated fluid sufficiently. — *Kedelph Wagner.*

#### COLOURS OF CUPRESSINEÆ.

BY JAMES McNAB.

THERE is an unusual circumstance this year connected with the appearance of a large group of various species of Cupressineæ cultivated in the Royal Botanic Garden, Edinburgh, which is worthy of being recorded—that is, the want of the usual reddish-brown tint which many of the species present at this season of the year, more particularly those indigenous to the eastern hemisphere. From many years' observation I have remarked that a large proportion of species belonging to the genera *Thuja*, *Biota*, and *Cupressus*, although perfectly green during the summer months, generally assume more or less of a reddish-brown tinge in autumn and winter, and return to their usual green colour during the spring months. Some of the varieties, such as the columnar *Biota orientalis elegantissima* and the globular *Thuja arcea*, are generally quite brown in winter, but during the spring months they assume the ordinary green tint, while in summer they take on a rich golden hue. Towards autumn the golden tint disappears, and is succeeded by the ordinary green colour of the original species, and finally they return to the brown, or winter, tint. In the nursery grounds of Messrs. Dickson & Sons, at Inverleith, is a number of plants of *Biota orientalis elegantissima*, received from Orleans last autumn, and lifted while in their golden condition. These plants have kept their colour throughout the

winter, and still possess the rich golden hue. This season, with the exception of the *Biota orientalis tatarica*, which is now conspicuous in various parts of the Botanic garden, on account of its reddish-brown colour, most of the eastern species are now of the richest green, and have been so during the autumn and winter months. The golden varieties just noticed have every appearance of passing at once from the autumn green to the golden summer tint. The cause of this remarkable anomaly I attribute to the great want of sunshine during the past summer and autumn, bright weather greatly assisting in maturing the juices, and so enabling the plants to go through their ordinary periodical phases. The Cupressineæ from the western hemisphere do not exhibit the same marked difference which is generally noticed in the eastern species, still in some instances a very slight brown or dull green tint is often observable. The higher brown tints are chiefly seen in varieties which, I suspect, have been produced in nurseries or gardens, and are evidently hybrids between eastern and western species. The *Biota cristata*, which was received from America some years ago, after a fine summer shows more of the brown winter colouring than any other American variety known to me. The same remarks hold good with several species of New Zealand Conifers, cultivated under glass, such as the *Dacrydium cupressinum* and the *D. Franklinii*. In general both these species take on a reddish-brown tint during the winter months; but this year the *Dacrydium cupressinum*, although slightly browned in the conservatory, is nothing when compared with the dark tints of former years, while no perceptible difference is this year observable on the plants of *D. Franklinii*, whether growing in the conservatory or in the open air. Numerous other examples might be quoted, but I think sufficient have been given to direct attention to this subject, and to elicit observation upon it.

**Buxus vulgaris pyramidata.**—One of the most remarkable and valuable novelties which has appeared for a long time is a perfectly distinct variety of the Tree-Box, which has been raised by M. Briot, director of the State Nurseries at Trianon, and is thus described by M. Carrière in the last number of the *Revue Horticole*. "It has numerous branches, which grow erect in a very regular manner, so that the tree has one of the most perfectly conical shapes imaginable, and it is moreover a vigorous grower, attains large dimensions, and has broad leaves of a handsome green colour; it forms of itself, without requiring the least clipping, splendid natural pyramids, which, when planted in an isolated manner or in rows, produce a very fine and pleasing effect; in short, it is one of the most ornamental trees that can be employed amongst choice subjects in the embellishment of pleasure-grounds." M. Carrière also very justly directs attention to the very great merits which the varieties of the Box possess in their almost innumerable diversities of foliage, their evergreen character, and their undoubted hardness.

**Tree Planting by the Sides of Railways.**—The Pacific Railroad Company are planting large numbers of quickly-growing trees along the track of the road, and particularly along the sides of the principal cuts. The preliminary work was commenced last season by ploughing up the right of way, 200 feet wide, where a considerable number of acres were planted, and 40,000 trees were set out, which are doing well. On the last year's prepared ground there is room for half a million trees. This year they are to break the ground up along the whole line of their road, each side of which will be planted with Oak, Hickory, Black Walnut, soft and hard Maple, Larch, white and gray Willow, and Box Elder. In addition, the Land Department of the Company has broken 120 tracts of 15 acres each, at different stations, where they will plant trees intended for the protection and adornment of the villages and towns that are to grow up around these stations.

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**The Dwarf Chinese Privet (*Ligustrum sinense nantum*).**—This variety differs from the type in having a dwarfer and more compact habit, which renders it an excellent subject for the margins of shrubberies, &c., and for small town gardens, or any position in which a plant of neat and bushy appearance with persistent or semi-persistent foliage, like that of *Lic. ovalifolium*, may be required. It has been already largely employed by M. Edouard André in some extensive park plantations.

**Cuttings of Conifers.**—In planting cuttings of Conifers, it will be found by far the best plan always to use strong well-ripened wood. In this respect, Conifers differ from the greater number of herbaceous plants, which often succeed best when the cuttings are taken from young shoots. Cuttings of Conifers with well-ripened wood are not very liable to damp off, and they root more speedily and grow faster than cuttings taken from young and slender shoots. Cuttings from some other trees, such as Poplars, Willows, Planes, &c., grow so much faster and better when they are made from shoots with strong well-ripened wood, as hardly to admit of a comparison between such cuttings and any others.

## CYCADS.

BOTH at home and abroad choice bits of scenery may often be met with that are well worthy of imitation in our gardens, both under glass and out-of-doors. Such a combination, for instance, of striking forms of vegetation as that represented on the annexed page could not fail to have a pleasing effect in a plant stove arranged in the natural style, which is what should be aimed at quite as much under glass as in our ornamental grounds. The Palm-like figure of the noble *Cycas circinalis*, in the centre, gives a good idea of the kind of effect which such plants produce when set in conspicuous positions in our plant houses, and accompanied by suitable surroundings. The small Aloe-like plant on the left is *Lomatophyllum borbonicum*, still a somewhat rare plant in gardens. Though Cycads to some extent resemble Palms, Pines, and Ferns, yet they possess features which prevent them from being mistaken for any of these types of vegetation. Their head quarters may be considered to be Australia and the Cape of Good Hope, especially along the frontiers of Kaffirland. There are, however, numerous outlying members of the order scattered through South America and the West Indian Islands, various parts of Asia, Madagascar, the South Sea Islands, and Mexico. Cycads in some instances have a grotesque and weird look about them; they have in general a simple, erect, stout cylindrical stem, bearing a large crown of pinnate leaves, which are very coriaceous in texture. They produce large cones, which enclose the seeds, the male and female flowers being set upon separate plants, *i.e.*, they are dioecious. From this general description there are, however, a few exceptions, as, for instance, in the case of *Bowenia spectabilis*, a plant from Rockingham Bay, North Australia, the foliage of which is bipinnate, *i.e.*, twice divided, and it is the only species with compound leaves known to belong to this family of plants. Some Cycads seem, when old, to become branched; of this class several examples exist in the Botanic Gardens of Amsterdam. Prominent among them is a magnificent example of *Encephalartos Caffra*, which has a straight stout stem 18 feet in height, at which point it divides into two equally strong crowns, each bearing a head of well developed leaves; in the same garden (which is wonderfully rich in grand plants of this order) may also be seen an example of *Cycas revoluta*, with a very stout stem, bearing five well developed crowns, and I have myself had a plant of the same species with two crowns. The only other instance of a Cycad becoming branched which has come under my notice was that of a male plant of *Cycas circinalis*, of which the Amsterdam garden possesses a plant with three branches. It may be added that species from the western hemisphere have stems that are quite slender. Cycads are as a rule slow in growth; and they must be allowed to grow when they please, and when they choose to lie dormant for a season, which they frequently do, any attempt to force them into growth by means of bottom heat or other stimulants seldom has the desired effect, and the large and fine specimens which adorn many of the conservatories of Europe must be of very great age, for from observations taken respecting the progress of trunk-making in *Encephalartos Caffra*, under cultivation, it would seem that nearly twenty years are required to form one foot of stem or trunk, whilst a plant of *Macrozamia spiralis*, growing in a collection near London, and which at one time belonged to the Messrs. Loddiges, of Hackney, has as yet but one foot of stem, although the plant has been in cultivation some thirty years at least. This peculiarly slow growth has its advantages as well as its disadvantages; for whilst those who have large specimens need have little fear of their outgrowing even limited accommodation, those, on the other hand, who have only small plants will feel dissatisfied because they cannot be made to quickly assume more noble proportions. Owing to this naturally slow growth, and the plants in many places being subject to destruction from bush fires, Cycads are not found in their native habitats in such profusion as are Tree Ferns and other plants that grow up quickly, and that therefore soon repair such damage. They are, however, by no means delicate in constitution, for the South African and the majority of the Australian kinds will thrive well in the open air during summer, and if sufficiently large, are grand objects for producing a sub-tropical effect in our flower gardens. The

kinds about to be enumerated comprise the majority of the species in cultivation. Recently, however, several new forms have been introduced, with which I am unacquainted, but which will doubtless prove valuable as ornaments to our conservatories.

## CYCAS.

To this genus, which gives its name to the order, few species belong. *C. circinalis*, *revoluta*, *squarrosa*, *media*, *siamensis*, *inermis*, *glauca*, *Rumuniana*, and *Rumphii* comprise all the kinds with which I am acquainted; the first is common in India and the islands of the Indian Archipelago, and furnishes a coarse kind of Sago, which is obtained both from the pith of the stem and also from the pounded nuts; the second species is a native of China and Japan, and also furnishes a quantity of inferior Sago, a circumstance which has led to their being erroneously called Sago Palms. Throughout Germany, but in Saxony especially, the leaves of this plant are always carried by mourners at funerals, and even friends of the dead who cannot attend the funeral are expected to send a leaf of this Cycas to lie upon the coffin. Thus leaves often fetch from one to three shillings each, according to size, and they are consequently largely imported for that purpose.

## ENCEPHALARTOS.

The different species belonging to this genus are South African, and mostly of large growth. Their stout cylindrical stems contain a quantity of farinaceous matter, which is eaten by the Kaffir tribes, and has thus led to the plants being called Kaffir-bread trees. They require thorough drainage, and should be potted in good rich sandy loam. Nearly all the species succeed well under conservatory treatment in this country; the principal kinds are *E. Caffra*, *Lehmannii*, *horridus*, *latifrons*, *lanuginosus*, *brachyphyllus*, *Ghellinckii*, *villosus*, *Altensteinii*, *Barterii*, *McKenii*, *giganteus*, *eycadifolius*, *tridentatus*, and *Natalensis*; other names may be found, but I have not seen the plants to which they are given, and indeed, some of the above in all probability are varieties only and not distinct species.

## DION.

We have but one species of this genus in cultivation, *viz.*, *D. edule*, which is a plant of very slow growth. The largest stems of it which have come under my notice have not exceeded 2 or 3 feet. The leaves are pinnate and very rigid in character. The seeds are large and yield an abundance of farina, which is used as arrowroot. The soil in which this plant succeeds best is a good rich loam, to which may be added a liberal quantity of sharp sand, and when the young leaves are pushing up a little warmth is of advantage; but at other times it should be kept in the greenhouse or conservatory, like the majority of the order to which it belongs; it requires little or no water during winter. It is a native of Mexico.

## STANGERIA.

This genus would appear to be peculiar to Natal. When specimens of its leaves were first sent home, so thoroughly did they resemble a Fern in venation, that the plant was described under the name of *Lomaria eriopus*. Further discoveries, however, dispelled this illusion, for it was found to make a stout, smooth napiform trunk, to produce its seeds in ovoid cones, and, in fact, to be very nearly related to *Encephalartos*, although differing from that genus in general appearance. *S. paradoxa* and *S. schizodon* are the only species with which we are acquainted; and the latter, which is of recent introduction, may eventually prove to be a variety only of *paradoxa*. The leaves are pinnate, the pinnae being usually oblong-lanceolate and obtuse, more or less serrated at the edges, and about 2 or 3 feet long. The treatment just given for *Dion edule* suits the *Stangerias* well.

## CERATAZAMIA.

This is a genus of Mexican Cycads, which differ from true *Zamias* principally in having two small horns upon the scales of the cones, whilst in *Zamias* they are quite smooth. They have long handsome pinnate leaves, and are fine ornaments in our stoves. They like good drainage, and for soil good loam and sand. The kinds at present in cultivation are *C. mexi-*

CYCAS CIRINALIS.

cana, Miqueliana, Kusteriana, and one or two others which I have not seen.

## ZAMIA.

The plants belonging to this handsome genus are principally natives of Central America and the West Indian islands; they consequently require a stove temperature. The principal representatives of the genus at present in cultivation are *Z. furfuracea*, *tenuis*, *eriolepis*, *fusca*, *picta*, *media*, *angustifolia*, *integrifolia*, *debilis*, *calocoma*, *Lindleyana*, *Skinneri*, and *Sieboldii*; in their native countries a very pure starch is obtained from many of these plants; their treatment should be the same as that for the last-named genus, except that a little vegetable mould may be added to the compost.

## MACROZAMIA.

The species of which this genus consists are, I believe, all natives of Australia; some of them were at one time placed in the genera *Lepidozamia* and *Catikidozamia*, but all have been again brought back, I believe, to the original genus. They are nearly related to *Encephalartos*, but differ from that genus in the arrangement of their flowers, and a peculiarity belonging to them is that the rachis in a young state is always twisted. In Australia the *Macrozamia*s generally grow in open forest-land, amongst various species of *Eucalyptus*, *Acacia*, and various other shrubs, none of which, however, afford them much shade or shelter. The soil in such situations is usually sandy or stony, and by no means rich. One species which has been variously named *Catikidozamia McLeayi*, *Catikidozamia Hopei*, *Lepidozamia Peroffskiana*, and which attains a height of some 60 feet, is never found in such situations, but on the contrary always affects very shady spots about the borders of or in dense scrubs, where the atmosphere is far moister than it is in open situations, and where the soil contains a considerable amount of decomposed vegetable matter. The following are the species usually found in European collections, viz: *M. Fraserii*, *spiralis*, *Peroffskiana*, *excelsa*, *elegans*, *corallipes*, *tenuifolia*, and *cylindrica*.

## BOWENIA.

I have reserved this until the last, because it is the most recent addition to this order, and contains the only known species of Cycad that has bipinnate leaves. As a genus it would appear to be nearly allied to *Macrozamia*, the chief point of distinction being its compound leaves. "I have," says a friend, "been paying some attention to the Australian Cycads, and one thing has struck me concerning *Bowenia* which is the most remarkable of them all, and that is, that it does not associate with the other Cycads, but is invariably found in very shady spots about the borders of dense woods, always growing in rich vegetable mould, and from the positions in which I have found it, I am fully persuaded, although an Australian plant, that in England it will always require to be grown in a warm house with a moist atmosphere," a remark which has been fully verified by practice. *B. spectabilis*, the only species known at present, was discovered by Mr. Allan Cunningham, some fifty years ago, but mere scraps of specimens of it only were brought home. The honour of introducing the plant into this country in a living state belongs to Mr. Walter Hill, director of the Botanic Gardens at Brisbane, who, together with Dr. Müller, of Melbourne, has done much for the old country in sending us quantities of these extremely interesting members of the vegetable kingdom. G.

## THE PAMPAS GRASS AS GAME COVERT.

Those who have travelled through North Wales on foot, and have passed from Conway by the Great Bangor Road, may have noticed at the foot of the Phenmaen Bach mountain, near the entrance ledge of Mr. Darbyshire, at Pendyffryn, a group of several hundred plants of this graceful Grass, covering a large island, and affording fine covert for waterfowl. The last time I saw it there were hundreds, if not thousands, of nodding plumes shimmering in the autumn sunlight, and producing a delightful picture. Scattered through the grounds of Pendyffryn, growing frequently in the clefts of the mountain, are many groups of the Pampas, under which, in that dripping climate, we are told game of all kinds delight to shelter. This place being bounded on the north side by the sea shore, and the group first alluded to being planted within a stone's throw of high tide, it is of course warmer

than mere inland situations would be, and hence in some measure the success. But still we are sure there are thousands of snug corners in the game coverts of the country where the Pampas Grass might be planted with advantage. The land at Pendyffryn is of the poorest description—little more than sea sand—and, though the plants grow slowly, they may be more hardy in consequence. At any rate, no one need hesitate to plant the Pampas Grass in the poorest soil, if they take the precaution to give it a peck or so of good soil to start in; for, once established, true to its native habitat, it can neither be swamped nor scorched to death. The only thing it suffers from this cold climate is water at the heart; for it is only when water accumulates in the centre of the plant and then gets frozen that it sustains any material injury. In the northern and midland counties, the remedy for this is to gather and tie the leaves together when frost sets in, and then to cover with a head of straw, so as to throw off the water. Thus protected, the Pampas Grass stood the severe frost of 1860, with the thermometer 6° below zero, in an exposed situation, almost without injury. In the southern or south-western counties the power of the plant to resist frost scarcely demands consideration. I therefore recommend it for covert purposes; and those who use it will not, I think, be disappointed. W. P. A.

## PEAT.

Those who have had experience in superior plant-growing, especially if they have lived in different parts of the United Kingdom, know how exceedingly difficult it is to procure good soils, especially good peat, which appears to be almost exclusively confined to Surrey and Kent, and from these two counties the majority of plant-growers are supplied. I have seen Wimbledon peat shipped at Putney for Worcestershire and for other parts of England, and I have also seen it sent out by the ship-load to Florence; for Orchid growing, too, it is sent to France, Russia, and Germany. In years gone by, Orchid peat, a tough, fibrous kind, used to be procured from Devonshire, but Wimbledon has generally been the stronghold for peat for plant-growers. For Heath cultivation, when ripened for twelve or eighteen months, it was exceedingly suitable. Plants did not grow rapidly in it, but the growth was steady and healthful, and the more delicate kinds lived and prospered longer in that peat than in any other. In softer kinds of peat they would grow for a time more rapidly, but, when tested on the score of endurance, they succumbed sooner than others more slowly grown. From Wanstead a useful peat used to be obtained. It was a dark, harsh, uninviting substance to look at, but when it had been aerated for a season many hard wooded-plants did exceedingly well in it. Its qualities were probably mainly mechanical, its hard nature when mixed in small pieces with softer peat having the property of keeping the whole porous for a longer time than a softer and more quickly decomposing soil could have done. I once saw some good peat which had been obtained from near Redditch, but it is not easily procured; and a fine fibrous peat may also be obtained from the Derbyshire Moors. Wrotham Heath, near Maidstone, likewise furnishes excellent material for the growth of Heaths and the finer hard-wooded plants. It is sent to different parts of the country in casks, after being freed from all extraneous matter. A.

**Value of Leaves.**—Some gardeners lay much stress on the value of tree leaves as a fertilizer. Dr. Nichols of the "Boston Journal of Chemistry" says, that such manure has only one-sixteenth the value of good stable dung.

**Peat.**—Seeing several inquiries in *THE GARDEN* and other journals as to where the best peat can be obtained, I have much pleasure in stating that I get the whole of my supplies of that soil from Mr. Epps, of Lewisham. The fine Ferns, Orchids, Palms, &c., at Sundridge Park have been planted in it, and prove by their luxuriant growth that it suits them perfectly.—JOHN WILLS, *Onslow Crescent, Onslow Square.*

## THE VOICE OF SPRING.

THEN that Thorn—too fond for waiting—  
Leaf with blossom antedating—  
All his naked ebon branches  
With sweet snows abundant blanches.  
These, therefore, the breezy showers  
Sweep like far-seen avalanches,  
Sudden from our Island Bowers,  
Nor let their silver magic stay  
To match the blossomed Hawthorn-spray.  
Next in fragrant order meet,  
To the season's summons sweet,  
Violet, Primrose, Daffodilly,  
Cowslip, Harebell, white Wood-Lily,  
All around by bank and field,  
Sweeping common, dell concealed,  
Their soft charms to Zephyr yield.

## GARDEN STRUCTURES.

## A NEW WALL COPING.

For the drawings and the following description of this mode of protecting a wall we are indebted to Mr. C. J. Cox, of Ravensbourne Lodge, Catford Bridge, who has invented it and proved its merits, and who is also the inventor of the Sidney seed sower.

The screen is formed of two or three half-inch boards 12 feet long screwed on to two pieces of bar iron as a bracket. One end of the bar goes over the top of the wall with the end turned down about 6 inches to hold it at the back; then from the edge of the bricks the iron must be long enough to take two or three boards as required, with two screws to each board; the iron is then bent down and back for the end to rest against the wall and form the bracket. To make the screens, place the two or three boards on the ground close together, then screw on the irons 3 feet from each end, taking care that the irons stand out far enough to take the thickness of the wall from the edge of the first board. The screen is now made, wanting only the cords to tie it down to prevent its being lifted by the wind. An iron eye is used, which is screwed in near each iron, and the cord is fastened to a staple in the wall. Should there be a coping to the wall the blacksmith can fit one iron and make the others like it. If preferred, the end of the iron with a hole in it can be secured on the top of the wall with an iron pin, to be left for future years when

View and detail of Mr. Cox's Wall-Coping and its supports.

the screen is removed. The brackets should be made of  $\frac{3}{4}$ -inch bar iron three-sixteenths of an inch thick, the screws of large size for the thin wood. The irons for the double screen can be made in one piece, as shown in the illustration. These screens are quickly put up and as quickly removed, are of little cost, and will last for many years, and one great convenience is that when not in use they pack closely one inside the other; any blacksmith can make the irons and gardeners can put them together. Mr. Cox's are up for the third season, and have not required any alterations. The village blacksmith made the irons and Mr. Cox made the screens.

**Garden Wheelbarrows.**—I should feel obliged if some of your contributors would be good enough to insert in the next number of THE GARDEN a sketch of the best style of common wooden garden wheelbarrow, ordinary size, giving the dimensions of the various parts, and any other necessary particulars, as those made in this part of the country are so clumsy and heavy as to be comparatively worthless.—JAMES A. MATHER, *Spencersville, Hamilton, N.B.*

A MAN who has travelled through New Jersey says that he saw some land so poor that you couldn't even raise a disturbance on it.

## ANCIENT EMPLOYMENT OF FLOWERS.

In the classical authors there is no mention either of nursery gardens or of florists, nor is an allusion ever met with to a posy or a nosegay. The nearest approach to the latter is in the secondary, but rare, use of the word, "fasciculus;" while the nearest to the name of florist—understanding, by his gentle craft, the production and preparation of flowers for decorative purposes—is found in that of "Chaplet-maker," the special and most celebrated employment of flowers with the ancients being for crowns and garlands, the manufacture of which assimilated, in a certain measure, to the elegant arts practised by our modern bouquetistes. The practice of wearing chaplets wrought of flowers appears to date from the remotest antiquity, the particular occasions upon which these beautiful ornaments were resorted to being those of festivity and rejoicing. There is plenty of illustration of it in the monuments of primeval Egypt; and, as there is good reason to believe that Egypt itself derived some of its most celebrated usages from the East, in a day still earlier, the probability is that the chaplet is almost coeval with the history of civilisation, which began where the sun rises—in the distant orient. In ancient Egypt the favourite flower was the Lotus, or "Rose of the Nile"—the *Nymphaea Lotus* of modern botany; though probably not that species alone, since, in some of the Egyptian paintings, the flower is coloured blue. With the Egyptians, at the time when Thebes was the proud and magnificent "hundred-gated" city that Homer describes—say ten to twenty centuries B.C.—as soon as a guest arrived at the residence of any person of distinction, he was presented with a coronet formed exclusively of this exquisite flower, one of the blooms being so placed as to hang forward over the centre of the forehead. The same flower was employed in the religious services of the country, the chaplet form being most usual, as beautifully illustrated in the insignia of Isis—that famous goddess whose very name is a romance, and in reference to whose bounty to mankind the flowers were interwoven with ears of corn. Many other flowers seem to have received much notice with the Egyptians, and to have been employed with taste whenever ornament was needed, as declared by the drawings and the painted linen found in the sepulchres; but the greater portion of the figures are so conventionalised as to forbid identification—a circumstance not surprising, when every succeeding age has at times departed from nature no less widely: witness the "patterns" even of to-day.

From Egypt the love of garlands passed into Greece, in the principal cities of which country, or at all events in Athens, during the pride of its intellectual and social eminence, the manufacture of chaplets was a fixed occupation. Whatever encouragement may have been given to other kinds of handicraft, this one, with the educated Greeks and all who possessed a lively sense of beauty, was deservedly and universally in favour. In Athens, we are told by Aristophanes, there was an established flower-market, where the vendors quickly disposed of what supplies they brought from their gardens.\* In the same author we read also of the "Myrtle wreath market," where one of his characters, a woman, is represented as maintaining herself by plaiting chaplets of this renowned and delightful shrub.† This would be B.C. 430. Theophrastus, also, B.C. 350, distinctly intimates that Roses, Gilliflowers, Violets, the Narcissus, and the Iris—whatever these names may signify—were cultivated extensively for sale. In the social customs of the people, it may be justly inferred that flowers were used with freedom. Brides, at all events, were crowned with flowers, but it was essential that they should be gathered by the bride herself, to purchase the bridal wreath being regarded as an ill omen. What would our brides of to-day, in England, think of their future, did a similar forecast attach to the dainty bouquets wrought so skillfully for their sovereign use? Specially employed for the chaplet worn by the bride was the shrub just named, the common broad-leaved Myrtle, which accounts, perhaps, for a separate market for Myrtle wreaths of different destiny, the fragrant evergreen in the abundance of its white bloom, with faintest shade of blush, being the emblem of love and chastity, and already consecrated to Aphrodite, representative herself, in the

\* Acharn, 212.

† Theophr, 450.

beginning, of the purest conception of the world's first principle.

#### CHAPLETS AS EMBLEMS OF VICTORY.

Chaplets were worn also by warriors and heroes, especially upon occasions of military display; these, however, would seem to have been composed not so much of flowers as of twigs of green leaves. Specially entitled to such chaplets, and wearing them as badges of their well-won honours, were the victors in the public games—those noble and exhilarating contests which constituted so fine a feature of the old Greek life. Represented in the athletic sports and gymnastic festivals of the present age—so energetically does old England, out of her inmost and spontaneous nature, preserve in the world all that was best and most glorious in the idea of ancient Greece the public games of that renowned country had a hold even more powerful upon the zest of its manhood, in the fact of the fame acquired at them taking precedence of all other that could be achieved, and being acknowledged by the gift of immense privileges. At the chief of these ancient games the successful competitors, those, at all events, who finished with *éclat*, were accounted the happiest of mortals; the games themselves, in their origin, and during their best days, were connected with the national religion, and even when tarnished, they still retained their primitive epithet of "sacred." The four principal institutions which went by the name of the games were the Olympic, the Isthmian, the Pythian, and the Nemean; the first so called from the place where they were celebrated—Olympia, in Elis, a state upon the western side of the Peloponnesus, the territory now known as the Morea; and the second from that famous neck of land, the Isthmus of Corinth, where they were held every three years, the Olympic extending the interval to five. Wherever held, and under whatever name, the contests were threefold—gymnastic, equestrian, and musical, and, in every case, of the most brilliant and vigorous character, the Isthmian superadding poetical contests, in which a share was allowed to women—a precedent that a certain university might do well to call to mind. The feature interesting at the present moment consists, however, in the immediate reward of victory having been one of these identical leaf-chaplets; and nothing can more strikingly demonstrate the all-sufficiency of the fame that was the real object of the contests, the desire of triumph that animated the Grecian youth, than the simplicity of the material they were wrought of. At the greatest and most popular of the games, the Olympic, the prize consisted of no more than a chaplet of "Cotinus" or "wild Olive," along with which was presented a "Palm-branch," every successful competitor receiving one of the same kind; while at the Isthmian, the crown was composed simply of Pine (exchanged at one period for Ivy); at the Pythian, of Sweet Bay, in ancient times called "Laurel"; and at the Nemean, originally of Olive, but afterwards of Parsley. Concerning some of the materials employed, there are discrepancies in the allusions of ancient authors, the fact, however, remains—that all were of the utmost simplicity. At the Pythian games, for instance, Apples consecrated to Apollo are said to have formed a portion of the reward, while at their first institution, or before the time of the beautiful but hapless Daphne, who was transformed into the first of the Bay trees, Ovid says the chaplet was wrought of the Esculus. (Met. I. 450, 451). Pindar, whose magnificent odes have reference wholly to these four great sets of games, and are named after them, frequently refers to the "Parsley crown," in language exquisitely poetic, but still with a strangeness of sound that makes one look back to see if the word has been really read aright. The use of this plant, like that of the others, had some kind of mythic origin. In every case the victor received also a "Palm-branch," while the scene rang with the jubilant shouts of the spectators.

#### DEDICATION OF PLANTS TO THE DEITIES.

Traceable as are the games to the earliest periods of Grecian civilisation and religion, the consecrated plants and shrubs being never lost sight of, it is not surprising to find these identical shrubs and plants originally devoted to the deities themselves. The Pine was sacred to Pan; the Myrtle, as we have said, to Aphrodité; the Olive to Athéné, and the Sweet Bay, or Laurel, to Apollo. Many another beautiful association of the same kind is met with while perusing the ancient poets,

as when Ceres wears her chaplet of Corn and scarlet Poppies; and Euterpe, the celestial virgin who presided over music, one of Jove's "nine blue-eyed flower-producing daughters," her crown or wreath of Roses; "Roses" with the ancients including, however, many other things that are sweet and deep-hued. When the "prima donna" of to-day steps forth in her crown of flowers, and is greeted with a shower of bouquets, she little thinks perhaps that flowers and music have been married ever since the beginning. Upon occasions of sacrifice and worship, the altars and temples were adorned with the foliage of the plants specially dedicated to the god or *genius loci*; and in regard to this it is very interesting to observe that the plants so employed were almost exclusively Evergreens. Very rarely, as in the case of Hercules and the White Poplar, a deciduous one is the kind selected. In this ancient dedication to the divinities of a plant green all the year round, there is more, too, than appears on the surface. Good taste would almost instinctively select such plants, but the substantial reason appears to lie in their symbolic character—the interior or poetic quality which in the days of the myths, and the fables, and

The dead but sceptred monarchs who still rule  
Our spirits from their urns,

was a delight so intense to accomplished thought and reverent feeling, and which, in regard to the significance of evergreens, is so conspicuously recognized in the Old Testament, where the spiritual gifts bestowed upon man by his Father in heaven are again and again denoted by trees of this description—evergreens, and evergreens only; the Cedar, for instance, the Fir, the Myrtle, and the Box. The idea there intended to be conveyed by the citation of evergreens is obviously that of permanence in the gifts that are symbolised; and upon the Grecian side of the blue Levantine water, among the worshippers of those

Eldest gods,  
Who in no statues of exactest form  
Were palpable,

no doubt there was a deep sentiment that so long as man was pious and just, so long might he rely upon divine succour and the unfailing largess of wealth and protection which he sought to win by means of votive offerings and the practice of virtue.

LEO GRINDON.

(To be concluded in our next.)

**Flowers in Cemeteries.**—A cemetery is most certainly the right place for a profusion of flowers. Of all out-door monumental decoration these are by far the most beautiful and appropriate. Those who have money to spend upon the last habitation of their friends and relations, and who piously desire to show their love and sorrow by some sort of outward sign, will act more wisely in paying some annual fee to the cemetery gardener to keep churchyard flowerbeds trim and pretty, than in laying out a vast amount of money among stonemasons, resulting in ill-executed angels, or trophies of cannon-balls and swords and cocked-hats, and other such insignia, hinting at the professional career of the deceased. The sums of money spent on these great ponderous symbolical monuments are often very large. But who that has groaned in presence of some hideous specimens of sepulchral bad taste, some terrible combination of cherubs and skeletons, of scythes and hour-glasses, of broken columns and ponderous marble clouds, and who has felt the beauty of one of these flower-begirt graves, will not testify to the superiority of the gardener's work over that of the stonemason? There is, too, a symbolism in the introduction of flowers here which makes them specially fit. These plants have come up from a root which itself was buried in the earth in order that the flower which we admire might bloom. They were put into the ground in the form of seed or bulb with no beauty about them to win our admiration, but they come up in due time arrayed in such splendour of decoration as cannot fail to fill us with admiration first, and then, as we think longer, with hope. They are grasses of the field whose perishable nature has been made before now to typify the insecurity of human life. Moreover, they suggest, at least, a certain continued supervision, a daily tending and care, which favour the idea that those to whose memory they are sacred are still held in recollection by their friends.—*Memory the Year Round.*

**Garden Statuary.**—A raw Jonathan, who had been gazing at a garden in the vicinity of New York, in which were several marble or plaster statues, exclaimed, "Just see what a waste! Here is no less than six scarecrows in this little ten-foot patch, and any one of 'em would keep the crows from a five-acre field."

GARDEN DESIGN.

A SMALL ROSE GARDEN.

THE annexed illustration is a representation of an instructive little Rosery designed for a villa garden. Though small, there is, however, plenty of variety in it, and there is, too, no want of room for comfortable inspection of the beds or for passing a friend on the walks, which are of Grass. The beds are designed so as to leave large spaces of Grass at their extremities, so that there may be ample accommodation for visitors without crowding; and these little patches of lawn set off the opposite beds to advantage, while from both lawn and walks are nice views of the surroundings. These are indicated by arrows, which show how a pretty nook or peep is obtained both by looking into and out of the Rosery. Of course, in every

best results; but not too thickly, for, though it delights in a Rose soil, it is apt to exhaust it too much. On the left of the plan larger spaces have been left than on the right, so as to afford an opportunity for a show of fine-foliaged plants together with innumerable little gems in the foreground. In planting such a garden as this, avoid narrow slips of border, and odds and ends of beds not bigger than tea-trays; on the contrary, have a full and open design. The two projecting masses serve to cut off the garden from too full exposure to the lawn, and in one of these, also, Roses are planted. The views from this little Rosery to the lawn are very picturesque, though the place is small, level, and formal in the outline of the ground. Some fine Cedars and other trees, and an open lawn, however, make up for deficiencies. The plan, it will be observed, has the additional advantage of a bird's-eye view. So that not only is it accurate as a plan, but as the

Plan of a Small Rose Garden.

instance the form of such a Rosery may be varied; its level may rise or fall, the entrances and exits may be anywhere, upon the principle of providing Grass walks and interspaces. One of the chief advantages of a Grass walk is its saving of room, and there is no edging to obstruct wheeling or other operations. The plants are on their own roots, a system of culture which possesses several advantages; one may, for instance, peg them down on the bed or let them grow up naturally; or, in short, the treatment may be annually varied according to taste. Another point worthy of observing in the annexed plan is the mixing of Roses with plants of other descriptions, such as Roses with ornamental Grasses, Roses with Gladioli, Roses with Lilies, and Roses with choice annuals. Than such combinations as these nothing could be more delightful. Mignonette may be sown broadcast through Roseries with the

plants are depicted in it on a small scale, the type of vegetation in each part may be recognised. Then, again, the names and not references are given, so that the plan is easily understood in all its parts. This is the second example we have given of a new and, as it seems to us, greatly improved style of garden plans. It will, we trust, lead to much improvement in garden design, as we hope by its aid to give plans of all the best designed gardens in this or other countries.

It is much to be desired that the plan of planting other choice subjects in the usually half-bare beds, as shown above, were generally adopted, as by its means many other beauties may be added to the Rosery. The culture of Gladioli or choice Lilies and the like here and there in the more open spaces between the Roses would not be detrimental to the production of the finest Roses in any appreciable degree.

## THE HOUSEHOLD.

## HOW TO COOK POTATOES.

THERE is probably no daily food which is capable of yielding us such a variety of healthful and tasteful dishes as the Potato; and yet many respectable families seem to have but one mode through the entire year, and that with as little care as possible—namely, boiling. Some might be interested to notice a few of the pretty ways in which I have seen them prepared in a pleasant rural home, where the mistress does not think it beneath her to give some time and thought to the planning of nutritious and even fanciful dishes. Do you say "A Potato is only a Potato when you have done and said all?" Ah! my dear Mrs. B., I agree with you exactly—a Potato is only a Potato; but so long as they are made a standard dish on almost every table, is it not better to give the preparation of them a little study and care, rather than to bring them into dinner cold, wet, and indigestible? So, while our husbands and brothers are pondering over the kind best adapted to the climate and soil, let us give a few minutes to the nice preparation of the fine crop they will put into our cellars by-and-bye. Care should be taken to select from the bin all alike in size, being sure to allow them just sufficient time to become nicely crisp and brown at the hour the remainder of the dinner is ready. They should not be allowed in the open oven one moment after "done," there to shrink, as if protesting against delay; neither to be sent to the table to wait five or ten minutes the movements of some tardy husband and children. Mashed Potatoes, that are nicely pared, boiled and dried, seasoned richly with salt, cream, or milk and butter, are always good, always nice, if smoothed down into the dish with care, and prettily spotted with pepper. The mashed Potatoes, left from dinner, make a fancy dish for breakfast, by making into little cakes or patties, with the hand, and frying brown in dripping or butter. The butter should be hot when the cakes are put in. The boiled Potatoes, left from yesterday's dinner, are very good chopped fine and warmed for breakfast in good milk and butter with salt and pepper. When you are boiling your tea-kettle to-night, you can boil half-a-dozen good sized Potatoes, and, when cold, slice them the long way, something less than a quarter of an inch in thickness. In the morning lay them one by one on the griddle, to slowly toast or brown in good butter or fat, salting them carefully and evenly, after placing them in a covered dish. Gentlemen always like these with their coffee; and these, or the Potato balls, are an addition to the tea-table when gentlemen are present. Still another way to fry is to pare the Potato round and round, like an Apple, until all is used, cooking slowly and evenly in a covered "spider," until brown. In the spring, when the Potatoes are poor, difficulty is experienced in preparing them to relish—pare and cut them half an inch in thickness, putting to boil in salted water until tender; then pour off the water and put on cream, or good milk, seasoning and thickening carefully with only a little flour. For those who have no milk, fresh boiling water can be used with nearly as good results. But I am outstretching my limits. For, a little aside, nearly all good housekeepers know the value of Potatoes in yeast, and that grated they make an excellent pudding with the usual additions. After all, perhaps, there is no form which is used, both for excellence and health, equal to the good old-fashioned roasted Potato.—*Cultivator.*

**Cabbage Soup.**—Cabbage soup is very popular in France, and is made with the *bouillon* of the *pot au feu*, as follows: "Take a large stewpan and line it with a pound or a pound and a half of smoked ham. Cut a Cabbage into four pieces, to extract the stump and the animals who perchance have introduced themselves to the interior, as their flesh is not necessary in the preparation of your soup. Now tie the Cabbage together, place it daintily in the stewpan lined and quilted with ham, and fill up the same to the height of the Cabbage with good *bouillon*. As ham is now the only meat in contact with the soup, boil up briskly. In ten minutes the stewpan will be dry, the Cabbage will have drunk up all the soup, and be one-third bigger than it was. Then fill the stewpan for the second time with *bouillon*, which will this time only diminish by one-half. Fill up for the third time, and cook for a couple of hours. Serve the Cabbage with the ham on a dish, and into a tureen pour the soup in which the ham and Cabbage have been cooked, mixed with some of your primitive *bouillon*."

**Removing Fruit Stains.**—Wash thoroughly in soap and water, then hold the stained spot over the smoke of lucifer matches. The sulphurous acid gas so suffocating to the lungs, will bleach out the stain.

**Raisins from Australia.**—We have just seen, says the *Gracer*, a case of Raisins sent over here as a sample of what can be grown and cured by the Australian colonists. This small consignment, the first of its kind that ever reached England, arrived a few days ago from Adelaide. The fruit is of fair quality on stalk, though dark and rather small. It has a deal of bloom on it, not unlike that on Muscats.

## THE FRUIT GARDEN.

## ON PLANTING VINES.

To those who are about to plant Vines, and do not happen to possess Mr. W. Thomson's "Practical Treatise on the Grape Vine," the following extract from that useful work may be of service:—"While I have planted Vines in nearly every possible way, and have found them all succeed well, at the same time there are some methods preferable to others, and I can strongly recommend the following from my own experience of it. It is probably in its details new, but it only requires to be described to commend itself to all who have any knowledge of such matters. I had a large house to plant, chiefly with Muscats, in April, 1861. I had a stock of one-year-old plants in 8-inch pots by me. I cut the rods back to 4 feet in February, and allowed them to stand in a cold Peach-house till the 13th of April, when the border was ready for their being planted. I shook all the earth from their roots, and spread them out on the soil of the border, one Vine to each rafter, and 6 feet apart, covered the roots with 6 inches of soil, and gave the whole a good watering with water at a temperature of 150°, and covered the surface with an inch of dry soil, to prevent, to some extent, the escape of the heat communicated to the border by the warm water. The Vines were just bursting their buds when planted; and, instead of adopting the usual practice of stopping or rubbing off all the buds but one or two, I allowed all to grow, and tied them carefully to the wires. By this means I had in some instances ten rods to one Vine, all of which during the season ran to the top of the house and partly down the back wall, a distance of 30 feet, and many of these rods were as strong as ever I had previously seen a single rod from a Vine the first year it was planted. In January, 1865, when they were cut down, the whole house was a perfect thicket of wood. I cut back all these Vines to within a foot of the front sashes, and trained up two rods from each the following season, fruiting them in 1866; and I need not tell those who know that a plant makes roots in proportion to its leaves, that Vines treated as I have described had an enormous excess of roots formed in the border as compared with others treated on the one-rod and pinching system, and that the bearing rods they made were in proportion to the extent and vigour of their roots in the soil. I measured one of them in December that, when planted in April, was not thicker than a writing quill, and I found that it was 3½ inches in circumference, and had ten rods perfectly ripe to the top of the rafters, a distance of 21 feet. If, instead of permanent vigour and productiveness, an immediate return were the object aimed at, I have no hesitation in saying that such a Vine would have yielded fifty pounds of Grapes the following autumn."

Mr. Thomson mentions another successful method of planting the Vine, but he deprecates the practice recommended by some of laying in a considerable portion of the stem with the roots, with a view to the more rapid development of the plant. He considers that "the vigour and the extent of roots that a Vine will make depend not on the length of the stem laid in the soil, but on the spread of healthy foliage it can get fairly exposed to light and air." The cutting away of the greater part of the heads of trees at the time they are transplanted has long been condemned as a practice not only needless but wrong in principle; and it seems difficult to understand why the Vine should still be condemned to endure the old treatment, in accordance with the saying of a bygone day, that "if you would transplant even your father you must cut his head off." I have often thought, when watching the operation of hedge planting, how much might be gained in the long run, if instead of cutting off the young Hawthorn plants within a few inches of the ground at the time of planting, that operation were deferred to the following season.

B. S., Uppingham.

## VINE-GRAFTING.

THIS subject has received considerable attention from cultivators of late. Various modes have been tried to improve the Vine by grafting, and the results, favourable and otherwise, have been reported in the different gardening periodicals from time to time. It has been proved that some Vines bear much better when grafted on a different stock than when growing on their own roots; that grafting has been the means, to a certain extent, of preventing varieties subject to cracking and shanking from doing so; and that the fruit is considerably improved in size and quality. My object in writing is not so much to speak of the results of grafting as of the practice of grafting itself. Loudon in his "Encyclopædia" describes a great many methods of grafting the Vine, and quotes his authors on the subject. Others have written their experience on the subject since, but none of them differing much from what is to be found in Loudon's works. Budding has been successfully performed by some; but inarching and grafting are the modes generally practised. There is

not much difficulty in grafting the Vine by any of the ordinary methods, but one of the best we have seen is that practised by Mr. Johnston of Terreagles Gardens, near Dumfries. Mr. Johnston has been a zealous and successful cultivator of the Vine for more than thirty years, and has experimented a great deal upon it. He has tried every method of grafting known, and has come to the conclusion that for Vines there is no better method than that which he practised for a number of years with every success, and which he has very properly termed "Dovetail grafting." It is simple, as well as sure, and fruit can be obtained from the graft the first year after its insertion. The grafting is performed in the following manner, and before the sap is in motion. The stock may be of one year's growth, or more; but young wood from one to four years old is preferable. The places selected for inserting the graft should be opposite a bud, or spur, with one or more buds to draw the flow of sap to the scion, which also prevents bleeding. Having selected the stock, the wood should be cut out of it from 2 to 2½ inches in length to a depth corresponding to the thickness of the scion, in the same manner as dove-tailing in carpentry is performed. The scion is then prepared by being cut into the pith, leaving the bud in the middle, and made to fit neatly into the stock, after which it is firmly tied with matting and clayed over, leaving a small hole opposite the bud, so as not to obstruct its growth. A little moss is then tied over all and kept moist for some time till the bud begins to grow. After it has grown some length, the opposite shoots are shortened, and eventually taken

off altogether. Mr. Johnston informed us that he has grafted old stunted wood in the above way, where the wood was bare; but in cases of grafting, young wood is to be preferred.—*The Gardener*.

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Gravenstein Apple.**—This variety, commonly used as an autumn Apple, is stated to keep till February and March, if stored in a cool cellar.

**Early Beatrice Peach.**—According to testimony from the districts of Columbia and North Carolina, this Peach is likely to take the lead as an early variety in America. A North Carolina gentleman has stated that he had a quantity of this variety fully ripe June 15th—two weeks before Hale's Early.

**The Paradise Stock.**—On the Pommier de Paradis stock, Apples may be planted 15 inches apart each way and when they begin to touch, each other may have each alternate tree removed, leaving the plantation at 3 feet apart each way. At this distance they will do to stand many years. The great thing with this stock is that all the large Apples, which are generally strong growers and slow bearers, bear abundantly in two or three years, and produce fine handsome fruit, generally better flavoured than when from the Crab or Doucin stock.—*Scott's Orchardist*.

**Low or High Espaliers.**—I do not think low training so good for Pears as for Apples, nevertheless on an espalier scarcely 6 feet high, and with six tiers of branches, I have a Marie Louise which has bloom buds on the lowest as well as on other tiers, and is not by any means what I consider a good specimen of that form of training. If the tree is only to be considered as to the amount of fruit it will yield, then unquestionably an 8 foot trellis is best, but I think such a trellis should consist of iron wires. The advantage of the 6 foot espalier is that it does not cast so long a shadow as a higher one, which in a small garden, with no great amount of room for growing vegetables, is a consideration. But in this, as in most cases, good management will achieve a great deal.—B. S.

**Changing the tops of Apple Trees to Pear.**—The following curious note on this subject has been sent by a Mr. Tipton, of Burlington, Kansas, to the *Horticulturalist* (New York):—"Pears grafted or budded on bearing Apple trees is the quickest, surest, and cheapest way I ever grew Pears. I never picked better Pears from standards, or any other under-growth for the Pear, than I have picked from old Apple trees topped and budded or grafted with Pears; and they always bore early and profusely. In large Apple orchards are sometimes found worthless, scraggy trees; on such I have practised changing to Pear. I never failed in two years to get a good crop. In some trees, the Pear would die out in five or six years, while others were healthy to my knowledge for eighteen years, and still doing well the last time I saw them, in 1865, in Franklin county, Ohio."

#### EARLY HARDY FLOWERS.

WE have often already written in praise of exotic plants, those unrivalled ornaments of our hothouses, which cause us to forget the frosts of winter, and transport us in two steps from the icy north wind into tropical regions, where we are rejoiced to meet with magnificent foliage, brilliant flowers, and delicious odours. But without losing sight of these wonders, there are in winter other and more modest garden enjoyments of which we can speak.

December has come! Our gardens are desolate and leafless beneath the cold breath of winter. Lovers of plant beauties are in mourning for their favourites, and lament their loss through the slow hours that must pass ere spring returns. If perchance a break of sunshine or a lukewarm day invites them to visit their sleeping plants, their saddened eyes will behold nothing but dried-up branches and withered leaves. Ungrateful in their disappointment, they know not that the winter also has its flowers, its tints, and its perfumes. These are rare beauties, 'tis true, but none the less interesting on that account. This one in the bare field, that under the silent bushes, others on the south fringe of the wood watch for a passing ray of cheering sunshine and bloom for an hour, even at the risk of being chilled and nipped by the returning north wind. Sometimes, anticipating its season, a Sloe tree, all white (not with snow, but with fragrant flowers), or near a sheltering wall some Marigolds, ambitious to brave the rigours of the declining year, enliven with their bloom the lonely ice-bound landscape; while *Stellaria media*, *Senecios*, *Lamiums*, early *Daisies*, *Colt's-foot*, and winter *Aconite* protest with all their might against the encroachments of frosty weather, and day by day renew their stout little corollas. Let us imitate the example which these resolute little flowers set before us, and, instead of giving up our gardens altogether in winter, let us see if some distant region has not, on our account, reserved some flowers that will withstand our harsh climate. We are thankful to say that we shall find some, although their number is small. At any other season we should not notice them—now they possess an intrinsic value for us.

In December and January, the early Japanese *Calycanthus* (*Chimonanthus fragrans*) and its large-flowered variety (*C. grandiflorus*) have their branches laden with Vanilla-scented flowers of a pale yellow colour starred with purple; *Rhododendron dahuricum* hangs out its Violet bells to the first rays of fleeting sunshine; the *Laurustinus*, with its empurpled buds, and its white honey-scented umbels of flowers; the Chinese *Jasminum nudiflorum*, besprinkled with golden stars; *Daphne Laureola*, with its pale green tubular blossoms, and its foliage glistening like polished steel; the handsome *Daphne Mezereum*, whose long, fragrant, rosy-purple spikes anticipate its summer suit of leaves; *Cydonia japonica*, draped in a mantle of scarlet, white, rosy, or flesh-coloured flowers, as the grower may desire; *Forsythia viridissima* and *suspensa*, with yellow bell-shaped blooms; *Magnolia conspicua*, its early buds essaying to burst their white tunics; the nut trees and the Conifers sprinkling the ground as with a shower of sulphur; the Bengal Roses, almost imperishable in their elastic vitality, and daily denying the warm country which gave them birth; the flowers of all these familiar plants would bestow an unexpected charm upon our neglected gardens. And are these all? We have, besides, the *Rosemary*, with its blue helmet-blooms; the *Kerria japonica*, just ready to unfold its golden plumes; the *Arbutus Unedo*, waving its silver bells; the *Cornus Mas*, to whose yellow little bouquets the eager bee will soon resort; the *Lonicera fragrantissima*, with its sweet scent of Orange blossom, and the hardy *Heaths*, whose buds are just entering upon the first shade of their ruby bloom—are all inexpressibly valuable foreign contributions to our winter gardens. Not one of them should be absent from a well-kept garden. Although most of them produce flowers alone at this season, yet these may well console us for the absence of the leaves, and we can happily supply the deficiency from a numerous host of evergreens, whose persistent foliage is now an inestimable boon, and whose great variety of aspect, shape, size, colour, and character cannot fail to satisfy all tastes. For large masses we have Portugal Laurels, *Laurus nobilis*, *Laurus Colchica*, *Laurus caucasica*, the common Laurel, *Hollies*, *Arbutus*, *Alaternus*, Japanese Privet, *Bac-*

charis, Garrya, Magnolia grandiflora, the Chinese Beam-tree, Box, Eleagnus, and Buck-thorn. Of Ivy, also, whose perpetual verdure of changeless green (constant alike in winter as in summer, the faithful decorator of the cottage and of the palace, the same in town or wild wood), is so precious when air and space are limited—of this we have an ample store to cover our walls, to hide ugly structures, and to form luxuriant groups of healthy green. For foregrounds and isolated groups, we shall find equally suitable subjects in Mahonias, Laurustinus, Aucuba japonica, Bamboos, Cistus, Cotoneasters, Daphne, Euonymus, Genistas, Privets, Butcher's Broom, Furze, and, if we do not mind the expense, Rhododendrons, Kalmias, Andromedas, Ledums, and Vacciniums; all of which require to be grown in peat soil. Let us now descend from shrubs to perennial plants. The series of winter flowers is agreeably continued by a succession of pretty plants not the less hardy because of their dwarf stature. The Snowdrop begins to pierce the surface and shows its white bells above the snow or the frozen soil. The Primroses are just about to unfold their flowers, while the Violets betray their presence by their sweet perfume; the Christmas Rose bravely throws out its broad white and rosy petals in the keenest frost; the Winter Aconite bursts through the soil, and shows its great golden blooms encircled by a collar of green, like a fine lady of the court of the Valois kings; the Periwinkle will soon show its blue blossoms in the shade; the Pansy spreads its rounded lobes, and boldly shows its black moustache between two diverging rays; the Winter Heliotrope vies in fragrance with the Violet; the Indian Chrysanthemums exhibit on their crimped and plaited heads, colours of the most varied hues; the Palm Cabbages, with their purplish, variegated, satiny leaves, twisted in a thousand pleasing ways, look like pigmy Palms with strange complexions; Hepaticas are radiant with lapis-lazuli, azure, or purple; and the brave little race of alpine plants (Aubrietias, Saxifrages, Ionopsidium, Gentians, &c.) are now beginning to awake to the remembrance of the hour when their brethren will bloom on their native mountains. It is therefore unjust and ungrateful to exclaim in winter—"Everything is dead." The fact is, nothing is dead; perhaps we shall be right in saying nothing even rests entirely. In nature, work is incessant, at all hours, by night and by day, under the snow as well as in the sunshine. There is no stagnation, however things may wear the appearance of sleep or of death. We should, therefore, ourselves obey this grand precept of universal activity, and employ for the common benefit every means which our kind mother Nature has placed at our disposal. Without work, no blessings could exist for us. Human labour is the prime source of all the enjoyments which a man creates for himself, and it not merely provides the means of enjoyment, but from its very nature heightens the zest and intensity of the feeling.

ED. ANDRÉ.

**Everlasting Flowers.**—The immortelle of the east (*Helichrysum orientale*), a native of Asia, has been known in Europe since 1629, but was only first cultivated in gardens about 1815. Its flowers, the symbols of friendship, or tribute to talent and genius, serve to make the garlands of immortelles which ornament the tombs of the dead in Roman Catholic countries. It is cultivated in France, in the communes of Lower Provence, where the soil slopes towards the Mediterranean. It succeeds very well on the slopes of Bandols and Ciota, which are exposed to the south and enclosed by walls of stone. It blossoms about the month of June. It suffers from heavy and continuous rains and strong dews, and only vegetates well on light, stony, and permeable soils. It is propagated by offsets, which are separated from the old stocks. The gathering of the flowers is made in the first days of June, before the bursting of the buds. As the flowers which are insufficiently formed or too full blown are rejected by the trade, it is important not to cut either too soon or too late. The collection is made by women, who tie them in small bundles, which are ordinarily dried on the walls of the enclosure. Finally, young girls are employed to remove the down which covers the ramifications. A kilogramme (2½ lbs.), by weight of these plants contains about 400 stems, each containing about 20 flowers. Each growing tuft of immortelles produces 60 or 70 stems. A hectare (2½ acres) will contain 10,000 tufts, producing annually 2,400,000 to 2,800,000 stems, yielding 16,000 to 20,000 bundles, or 5½ to 6½ tons in weight, of immortelles.—(Gustave Heuge.)

## THE GARDEN IN THE HOUSE.

### SONCHUS LACINIATUS AS A TABLE PLANT.

DOUBTLESS some one will exclaim, "What! a Sow Thistle to garnish my dinner-table! Preposterous!" But wait a while, there are beauties even in the Sow-Thistle family, though Dominie Sampson might have cried prodigious! had he heard such an assertion made—beauties, too, of such an exquisite kind, as will make you quite forget the stings which the spines of some of our native kinds gave you last summer, when trying to pull them out of the flower border or the rockery. The plant in question is what is termed suffruticose in habit, as, indeed, are several of the species of this genus, which are to be found in the Cape de Verd Islands. It attains a height of some 2 or 3 feet, or even more, and, singular to relate, it is in full beauty during the dull, dreary, dirty, disagreeable weather we have so recently experienced. It should be grown with but a single stem, as in that state its peculiar beauty is displayed to the best advantage. The leaves are long, thin in texture, and

*Sonchus laciniatus* as a Table Plant.

pinnate, or perhaps the word pectinate would give a better idea of their appearance, and their colour is bright green. Under artificial light they appear almost transparent, which, added to their pendant arching habit, render this Thistle a really charming subject for the embellishment of the festive board. It may be grown in small pots for the convenience of placing it in ornamental vases, and the soil should be loam, peat, and sand, in the proportion of two parts loam to one of peat and sand; the drainage must be perfect, and during the time it is growing water must be freely supplied, but during winter, when at rest, just sufficient to keep it alive is all that is necessary. As far as my experience of this plant goes, I have found it to strike tolerably freely from cuttings made from the small side shoots, but the stout main shoots will not strike readily. It is a native of the Cape de Verd Islands, and may be grown in an ordinary greenhouse.—*Farmer.*

**Flower Gum.**—For what purpose is this employed, and what is shell-lac from which it is said to be prepared?—J. S. [Flower gum is used to render the petals of some kind of flowers more persistent than they naturally would be. It is consequently much in request with bouquet makers. The shell-lac, of which it is prepared (see p. 223) is a resinous gum produced by an insect called *Coccus lacca*.]

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**Conservatories.**—Camellias are at their best, both in borders and in pots, and Azaleas are coming rapidly into bloom. Such as have been forced, and have done blooming, may be repotted, placed in a warmer house, and syringed twice a day. Rhododendrons in conservatories that have been kept above 40° during winter are now in great beauty; such as are grown in pots, and are required to bloom at once, should be subjected to a little higher temperature than that in which they have been placed. Successions of *Cytisus racemosus* should be kept up by means of fortnightly introductions to the forcing pit. There is no difficulty now in supplying *Callas* in flower, for a little extra heat and moisture is all that is requisite until the spathes are formed. Divide the roots of such as have produced suckers, and pot each separately; they should never be dried off. *Imautophyllum miniatum* is now in great splendour, and should receive a little weak manure water while in flower, especially if the roots are much confined. *Hebeclinium ianthinum* is one of the most desirable of conservatory spring-blooming plants, for its great *Ageratum*-like lavender-coloured flower trusses are very striking and distinct from those of its associates. It forms abundance of roots without making many leaves; therefore the roots should be kept within small bounds, and should be fed with manure water. The bright weather of the past fortnight has driven bulbous plants quickly out of bloom, except where well shaded; such as are required for the latest succession should, therefore, be placed out-of-doors against some wall or thick hedge having a north aspect. Liliams of the speciosum section should be kept growing, but they should be kept as yet but sparingly watered; a position for them near the glass is of immense importance in all cases, except in that for the latest supply, which may be set out of doors. Pot *Petunias* in loam mixed with some well-decayed manure; keep them growing, and strike them according to their requirements. *Tropeolum canariense* makes a fine pot or dwarf trellis plant for a cool conservatory, if sown in heat in March and potted on as required. The specimens of *T. tricolorum* that have done blooming may be turned out into a cool house or light shed; do not apply any more manure water to those still indoors, otherwise the ripening of the corms will be retarded. Plants of *Veronica Andersoni* that have been kept at rest for the past two months may now be shaken out, repotted, and the shoots shortened back a little. A few plants of *Plumbago capensis* should be pruned, potted, and kept in a little heat until they make fresh growths. Train *Clematises* to trellises or rafters; these form magnificent permanent climbers either for indoor or flower garden purposes. *Fuchsias* should be started into growth as occasion requires. They like a moist heat and the shoots should be pinched as they advance in growth. *Colenses* must be kept near the light, potted as they require it, and pinched in order to maintain symmetry of growth. Prune, pot, and start *Daturas* into growth, and use the best ripened parts of their shoots for cuttings. *Salvias* make good indoor decorative plants, especially *S. patens* and *S. splendens*; therefore cut back the branches, pot, and start the plants into growth in moderate heat. French and fancy *Pelargoniums* should be kept as near the glass as possible, in order to induce a stubby growth and abundance of flowers; those required for early blooming should be subjected to an increased temperature, as should also the zonal ones.

**Bedding Plants.**—If *Calceolarias* wintered in frames have not been transplanted farther apart in fresh free compost, do so at once, and pinch off all flower-spikes and tall shoots, it being necessary to encourage a dwarf growth. Such as were propagated in boxes in heat this spring and are now well rooted should also be transferred to frames and set farther apart than they have been. Well rooted plants of *Lobelias* raised from cuttings, and seedlings that have been pricked off thinly into boxes, and which are now beginning to touch one another, should likewise be transplanted into a frame set on a hard bottom and into which 6 inches deep of light rich soil has been put. *Ageratums*, *Tropeolums*, *Verbenas*, *Gazanias*, &c., should be similarly treated, and care taken to protect them from frost at night. *Pelargoniums* should not be planted in this manner; on the contrary, they should be kept in pots in a cold frame; where two plants are growing in each pot, however, separate them and pot them singly, and keep them in a close frame for a short time afterwards. The variegated-leaved kinds, such as the bicolors and tricolors, should be kept in rather warm quarters. The propagation of these may yet be preceded with, and the cuttings potted singly before their roots are more than an inch long, otherwise they might get broken. *Dahlias* may still be increased by means of division of the old roots or from cuttings; after they are well rooted, plant them amongst some rich free soil in a frame and protect them from frost. Keep *Echeverias* in cool houses or pits, or arrange the pots or boxes containing them on the floor of some cool Peach-house or Vinery.

Those increased by means of the side shoots, leaves, or seeds this spring should be nursed carefully in a moderately warm place, so as to encourage a good growth before they are planted out. *Echeverias* or other succulents required for bedding should not be permitted to bloom indoors; indeed flowers at any time are only produced at the expense of the beauty of the foliage. The little yellow variegated *Mesembryanthemum*, now so common in our flower gardens, although tolerably hardy, thrives admirably in heat—a course that should be resorted to in order to have cuttings that will make good plants before bedding-out time. An ordinary greenhouse is, however, sufficient protection for it in winter and spring. *Alternantheras* are deservedly admired as carpeting plants. They should, therefore, be propagated for that purpose as expeditiously as possible, and the greener the foliage the more easily will the cuttings strike root. *A. amena* has this year been rather sparing of young wood; it is, therefore, difficult to obtain a stock of it. *Iresines* and *Colouses*, especially *Verschaffeltii*, should be propagated, potted singly, pinched, and kept near the glass in a warm frame or house. *Perilla* should be pricked out into boxes, and kept near the glass in any of the fruit-houses in which there is a little heat. In the case of *Stocks*, *Asters*, and *Everlastings* sown on gently-heated hotbeds or in boxes, the sashes should be tilted up a little night and day, and the seedlings shaded from strong sunshine. As soon as they are fit to handle, prick them out into other frames or into a well-sheltered south wall border, with a few Broom or Spruce branchlets stuck in front of them. French and African *Marigolds* and *Tagetes signata* *pnmila* should be raised in heat, and, after they have come up, should be pricked off into boxes or pans, which should still be kept for a time in heat. Such hardy plants as have been wintered indoors should be transferred to the open ground at the earliest convenience.

**Hardy Fruit Garden.**—Wall trees must now be protected. Outdoor fruit trees as a rule promise to produce heavy crops. Plums are laden with flowers, and Cherries have set blossom buds in abundance; Pear trees, too, are most satisfactory. Finish grafting, more especially that of stone fruits, as speedily now as possible. If not already done, mulch between the rows of Strawberries with litter, the nutriment from which will be washed down to the roots by successive rains, leaving the surface clean for the fruit to rest on when ripening. See that Raspberry bushes are securely fastened to their supports; in most cases they are grown erect and tied to wooden stakes, but in others one-half of the rods from a stool is loosely plaited and brought to meet a similar number of canes from the next, thus forming a series of arches, whilst in other instances the rods are cut about 3 feet in length, and are tied together without a stake; in some other cases, too, they are tied to wires or trellises.

**Kitchen Garden.**—Cabbages and Cauliflowers have started actively into growth; the hoe must, therefore, be kept at work amongst them, as nothing is more productive of good to vegetables than a clean and frequently-stirred surface. Make a general sowing of Cauliflower, and prick off into a warm corner or border those sown last month, as soon as they are fit to handle; and in the event of cold or wet weather occurring, handlights, frame sashes, or hoops and mats may be employed for their protection. Sow some of the early kinds of Broccoli, and, in cold localities, also late sorts. Of the fine curled Italian Endive, sow some seeds in a brisk temperature for early use; but if not sown in a strong heat, the plants are apt to run prematurely to seed. The main crop of Beet may now be sown; but in warm counties towards the end of the month will be soon enough. It likes an open situation and trenched ground that has been manured for the previous crop. Thin Parsnips when they appear, but not finally; some growers prefer sowing early in this month, but even about London Parsnips are sown at the same time as the spring Onions, for they take a long time to germinate and they are not liable to "run." Sow Chicory thinly in rows, about 9 inches apart, for winter forcing. As soon as Globe Artichokes have made growths about 9 inches long, slip them all off except the three strongest, which should be retained for the summer's produce. The best of the slips should be chosen for a new plantation. Cut the heel attached to each smoothly, and then plant them 8 or 9 inches apart in clumps of three, each clump about 2 feet apart, in rows 1 foot asunder, in a deep rich sandy loam, and an open situation. Sow some summer Savoys in a warm border, and increase the stock of the winter kind either in the same way or by dividing the old roots. Fresh Tarragon plantations may be obtained by planting rooted slips from the sides of the old roots; Tansy may be increased by division of the roots, and Sorrel by sowing or dividing the roots; Balm, Burnet, Thyme, and Mint may be propagated by dividing the roots, and Hyssop, Fennel, Sage, Rosemary, Pennyroyal, and Lavender by slips, which if rooted are so much the better; while Chervil, Clary, Sorrel, Samphire, Parslane, and Borage require to be raised by means of seeds. Basil and Knotted Marjoram are best raised in a gently heated frame, and well hardened off before being finally trans-

planted. Preserve a piece of a warm border for French Beans, but it is rather too early to sow them yet. Before sowing open the drills in the morning, if fine, and sow the seeds in the afternoon. Sow Cardeons where they are to remain in lines 4 feet apart, so that three seeds may be in a clump 2 feet asunder in the row. In the northern counties, Gherkins may be sown in gently heated frames, but in warm and southern localities May is soon enough for sowing; whilst if a well-sheltered warm border be selected, they may be sown in lines 4 or 5 feet apart out-of-doors in the latter half of May, when they yield their crop at the end of July and in August. Keep up a succession of Peas and Beans, and attend to timely staking. Successional sowings of small salading must be regularly attended to and Lettuces transplanted, sown, and thinned. Sow Turnips as required, and in case of the coming summer being hot and dry, a small sowing of early white Vienna Kohl Rabi may be found useful, as it is of tolerably good flavour and withstands the drought of summer better than Turnips.

#### MARKET GARDENS.

The genial weather of the past fortnight has been instrumental in forwarding all sorts of vegetables. Winter Spinach is now pushing up strong fleshy leaves, therefore have the beds cleaned and hood. Hoe and clean Parsley beds after the leaves have been picked for market, and, if not already done, sow some seeds for autumn and winter bearing; March, however, is the best month for this operation. During the last three weeks there has been plenty of Seakale obtained from the open fields, in which it is cut as soon as the tops are discerned making their way through the earthed-up soil. Finish the earthing-up of Asparagus ridges. Parsnips are now beginning to appear; therefore, where Lettuces are planted between the lines, they should have the earth about them loosened with a short hoe, and the alleys between, *i. e.*, where the Parsnips were sown, raked smoothly, but not deeply, with a foot-wide iron-toothed rake, so as to break the surface and to facilitate the egress of the seedlings through the soil. Earth-up Beans and draw the rake over the soil where they have not yet germinated. Beans are generally planted in rows 2½ feet apart, with a line of Cabbages between them, the latter being removed before the former require the space. Radishes will now grow quite freely without coverings of litter—*i. e.*, if the weather keeps fine and birds are kept off them. Therefore, remove such protections, which should be placed in the bottom of the manure heap to soak and rot. Still, however, keep litter on Rhubarb, for under it the leafstalks always come cleaner and crisper than when grown uncovered. Plum trees are in full flower, Pear trees are extremely promising, as are also Cherries; indeed, the fruit harvest, if uninjured by frosts and dry easterly winds, bids fair to be a good one. Grafting in general should now be proceeded with, whip-grafting being the mode generally employed. Stone fruit should be grafted first; Apple trees may remain until the last. Large trees or branches may be grafted just as easily as young trees; and young standards, when grafted, may be bent down so as to have the parts in union inserted in the soil, provided the weather is dry; but good claying and attention generally renders such treatment unnecessary. Mushroom spawn has been sadly destroyed this winter. Cucumbers should now be planted out in frames, and well covered at night with litter. Keep the frames close for some time after they have been planted out. Those who grow Melons should now plant them in the frames in which they are intended to be grown.

The following amusing case of continental red-tapeism is related in a foreign periodical:—A country apothecary, wishing to collect Digitalis in a wood which belonged to the State, made an application to the local authorities, offering to pay six francs (5s.) per annum for the privilege. The official to whom he applied forwarded the request to his inspector, who, in his turn, sent it to the conservator of the department, by whom it was transmitted to Paris, to the Director-General of Woods and Forests, who handed it over to the Minister of Finance. Having carefully studied the application, the Minister of Finance despatched it to the chief Director of State lands, who posted it to the departmental Director, instructing him to inquire into the justice of the applicant's petition. The latter, having satisfied himself on this point, sent back the papers with a favourable report to the chief Director, who then remitted them to the Minister of Finance through the medium of the Financial Secretary. The successful petition, with the required permission to gather the Digitalis duly attached, was now passed on to the Director-General of Woods and Forests, who sent it to the conservator, from whom it went to the inspector, and from him to the head wood-ranger. In the meantime, however, the applicant happened to die, and when the precious permission arrived, his successor could not avail himself of it that year, as the season for gathering the Digitalis had passed. We concur in the remark which our authority makes on the above—"Se non e vero, e ben trovato."

#### SPRING FLOWERS.

THE subjoined is a list of hardy plants, all of which are now in bloom out-of-doors in the Hale Farm Nurseries, Tottenham.

Andromeda polifolia	Daphne collina	Fritillaria pyrenaica	Narcissus incomparabilis
Anemone	Mezerium	Gagea fistulosa	and vars.
apennina	Dentaria digitata	lutea	odorosus
coronaria	flor. albo	Helleborus in var. (almost past).	poeticus and vars.
memorosa and vars.	Dielytra eximia	Hepaticas in var.	Polyanthus
stellata and vars.	Dodecatheon	Hyacinths in var.	Pseudo-
Arabis of sorts	Meadia	Iris	Narcissus minor
Arisema precox	Dondia	persica	Tazetta
Arum	Epipactis	tuberosa	Telamonius
crinitum	Draba	Laurustinus	Ornithogalum Bergii
Aubrietias of sorts	aizoides	Muscari	Pansies in variety
Bulbocodium vernum	boeotica	botryoides	Polyanthuses in var.
foliis striatis	borealis	album	Potentilla alba
Caltha	glacialis	carneum	Prinulas in var.
palustris fl. pl.	Empetrum	pallidum	Rhododendron precox
radicans	nigrum	ceruleum	Sanguinaria canadensis
Cochlearia officinalis	Epimedium macranthum	comosum	Saxifraga calyciflora
Corydalis	Muscicium rubrum	atrocaeruleum	ciliata
bulbosa	pinatum	monstrosum	Scilla
rubra	elegans	Heldreichii	amena
cava albiflora	Episatum arvense	moschatum	bifolia
Crocus	Erodium	neglectum	alba
Aucherii	romanum	pallens	rosea
sulphureus	Erythronium americanum	racemulium	rubra
striatus	Dens canis	racemosum	Cupaniana
vernus	albidum	majus	sibirica
many garden varieties	album	Stevensii	Scopolia carni- olica
Cyclamen	purpureum	Stranzwaysi	Thalictrum anemonoides
Atkinsii	rosicum	Myosotis	Triteleia uniflora
Coum	Fritillaria imperialis	sylvatica	
persicum	Melagris	Narcissus	
repandum	præcox	Ajax and vars.	
vernum	pubica	calathinus	
Daisies, double- flowered		centifolius	
		Diomedes minor	

#### COVENT GARDEN MARKET.

APRIL 10TH.

**Flowers.**—Hyacinths and Tulips in pots are yet plentiful, and of the flowers of the former large supplies are being obtained from the open ground. *Cytisus racemosus*, *Hoteia* (*Spiraea*) *japonica*, spring-flowering Heaths, Fairy Roses, zonal and other Pelargoniums, Azaleas, Cyclamens (some of which are yet in fine condition), Ferns, &c., form the bulk of the pot plants. Cut flowers consist of Tea-scented and other Rose-buds, Gardenias, Camellias (principally white), blue Cinerarias, Pinks, and Carnations, Lily of the Valley, Orchids, and others. Besides these, there is a goodly quantity of hardy flower roots, such as Daisies in flower, Hepaticas, Pansies, Polioxes, Hollyhocks, Lupins, Carnations, Sweet Williams, Primroses, Polyanthuses, and several kinds of hardy climbers. There are also large Fern roots, conspicuous amongst which are those of the Royal Fern.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 6s.; Cobs, per lb., 2s. to 2s. 6d.; Grapes, hothouse, per lb., 15s. to 30s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 4s. to 10s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 6s. to 10s.; Strawberries, per oz., 6d. to 1s. 6d.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 5s. to 10s.; French, 10s. to 30s.; Beans, Kidney, per 100, 2s. to 3s.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, 6d.; Cauliflower, per doz., 3s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 6d. to 2s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz., 1s. to 2s.; Mushrooms, per pottle, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 3s. to 6s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 4s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 5s. to 8s.; Potatoes, per bushel, 4s. to 8s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsify, doz., 1s. to 1s. 6d.; Savoys, per doz., 2s. to 3s.; Scorzoneria, per bundle, 1s.; Seakale, per basket, 1s. to 2s.; Shallots, per lb., 8d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, per bunch 3d. to 6d.

#### ANSWERS TO CORRESPONDENTS.

**DRACÆNAS** (W. F.)—*Dracena indivisa* and *Cordylina indivisa* are the same thing.—**BOOK ON HORSESHES** (Gardener).—There is no good cheap book on the subject. Procure the illustrated catalogues of a few good firms.—**NAMES OF PLANTS** (Homo).—*Cupressus Lawsoniana*; G. W.—1. *Bryum caespitosum*. 2. Probably *Polytrichum juniperinum*, but there is not a rudiment of fructification, so this is only a guess. 3. A *Hypnum*, but in the absence of fruit it may be almost anything.—**PRACHES** (Homo).—You may disbud those on walls as soon as the young shoots are large enough to handle.—**SHADING** (W. W.).—You must have means of shading a little during bright days in summer.—**FORMING HERBARIUM** (Under Gardener).—You will find a description of how to form an herbarium at p. 213 of the last volume of THE GARDEN.—**CYCLAMENS** (S. H.).—Mr. Clark, market gardener, Twickenham.—**SKELETON LEAVES** (Anxions).—Macerate the leaves in soft rain-water until all the soft or cellular portion is decomposed, when it can be removed with a very soft tooth-brush. Then place them in clean spring-water, to which a small quantity of chloride of lime has been added, in order to bleach them. Lastly, dry them between sheets of blotting paper, and leave them exposed for a short time to the sun and air.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

—o—o—o—

### REMARKABLE STRAWBERRY CULTURE.

A VISIT to Mr. John Westcott's fruit garden at Topsom, Devon, on the 2nd inst., afforded me great pleasure, inasmuch as it enabled me to see cleanly and orderly cultivation carried out on about nine acres of market garden ground, partly devoted to healthy fruit trees that promise an abundant harvest. I was especially delighted with the skilful way in which Mr. Westcott cultivates Strawberries under glass, for during the many years I have been in practice I have never seen this delicious, wholesome, and delicate fruit brought to such perfection as it is here. In the houses, which are long, narrow, and low, and heated by means of hot-water pipes, are thousands of pots of Strawberries in various stages of growth, all cultivated in a masterly manner. Mr. Westcott having made Strawberry culture under glass a speciality for some years past. The pots which he uses are not large, nor are his plants overgrown or crowded with an over-luxuriant foliage. On the contrary, they are grown in what are called 48-sized pots, and some in small 32-sized ones. Thus managed, the plants are dwarf and sturdy, and are furnished with comparatively small foliage, set on very short footstalks. Their crowns are large, firm, and prominent, and previously to bursting get as large as a pigeon's egg. Thus prepared, when placed under glass they produce a host of sturdy flowering stems, each of which is, in due time, covered with plenty of flower-buds, that are induced to open strongly. It is really a grand sight to see a long house full of plants, whose flowers are thrust up above the foliage in such profusion. After the plants come into bloom, the next process is fertilising the flowers, in order that an even and heavy crop of fruit may be produced. This is a point in Strawberry culture under glass which requires particular attention. In all kinds of seasons, early or late, with the weather dark, cloudy, windy, foggy, and stormy for days; with snow, hail, and vapour, such as our climate invariably favours us with during the first three months of the year, many a persevering, practical, attentive man has failed, by some means or other, to set and swell-off a bountiful crop of fine fruit, even after a glowing prospect both as respects plants and blossoms; yet, during this critical and important stage in early Strawberry culture, Mr. Westcott is quite at home amongst his Strawberries, which are induced not only to blossom strongly, throwing their trusses of inflorescence straight up to the light, as boldly as if it were in the flowery month of May, but every bloom also gets quickly and well set. During the blooming time, the floors of the houses in the evening are as thickly strewed with fallen blossoms as the ground of a Cherry orchard, after a fine sunny and somewhat windy day. The fruit is at once set and begins to swell, without even a temporary halt. This season the plants have set a beautiful crop of fruit, which is swelling fast, and hanging in clusters around the pots as thickly as Hops, staking or propping being little practised here. The fruit, too, is fed, and swelled out in the greatest perfection. Indeed the way in which such heavy crops are swelled off and finished is quite marvellous. The colour is all that could possibly be desired, and the texture of the fruit is so firm that there is no difficulty in packing and transporting it safely to the London, Bath, Taunton, Exeter, and other markets. The varieties which Mr. Westcott cultivates at this season for his main crops are the Excelsior and the Claimant. It appears to me that Mr. Westcott pots his plants early, ripens them well, takes care of the plants in the autumn and early winter, gets them under glass early, allows them plenty of time to show their blossom; but that after they are in flower he gets them fertilised and set quickly, and that he allows no loss of time afterwards in swelling off and in perfecting the fruit—all good points in Strawberry forcing.

JAMES BARNES

### TWO NEW WALL PLANTS.

MANY seem to think that Ivy, Periwinkle, Jasmine, Honey-suckle, the Rose, the Bignonia, and others are amply sufficient for these purposes. Without for a moment disparaging these or such exquisite wall plants as *Linaria Cymbalaria*, common Wallflowers, and others, I beg to introduce two more, both suitable for clothing walls, and for half-concealing, half-revealing ruins and rock-work. One of these plants is for the inside, the other for out-of-doors. One is green as an emerald, the other blue as the bluest depth of an Italian sky. The majority of rocks, walls, and ruins, when dry, are of a white or red hue. What can there be more artistic than clothing them with blue drapery, an operation at once simple and easy? A few seeds of *Myosotis dissitiflora* had probably been carried by wind or birds and dropped on a rough stone wall with which I am acquainted. They grew; and now these compact cushions of tufted beauty are the delight of all eyes. They had no care, no attention; were, in fact, unseen until their flowers burst forth from the hard bosom of the stones and draped them with surpassing loveliness, a result too charming to keep to oneself. I have already done what I could to spread this loveliest of all spring plants widely over the surface of our gardens. I now entreat your readers to let it climb, and beautify their walls. Then, again, how beautiful this Forget-me-Not is among other plants, such as the Golden Feather, pineushioning the hardest rocks with patches of brightest yellow: or among Wallflowers, or against Golden or Silver Ivy, what could be more lovely than large flecks of blue? My other plant is a humble Grass or Rush, viz., the *Isolepis gracilis*. It is almost, if not quite, hardy. But if you want fully to develop the elegance of its slender beauty, grow it in a stove temperature. The long rushes or leaves then double their usual length and delicacy, so much so that they cannot support themselves, but droop and fall in the form of elegant spray. Pot plants of *Isolepis* are charming; for tiny baskets it is admirable, and on brackets it is perfect; but on a wall, faced with rockwork or virgin cork, it is most exquisite. Hardness, straightness, formality, even the existence of a wall itself, are all lost amid the refreshing greenness of this charming Rush. On a damp wall the smallest modicum of soil suffices for its growth: The white roots cling to the stones and drink in moisture from every chink and cranny, and the tops delight, as I have said, in the moist atmosphere of a stove or Orchid-house. Beautiful by itself, it is, if possible, still more lovely when intermixed with two of the most delicate of the Maiden-hair Ferns, viz., *Adiantum Capillus Veneris* (which, though scarcely hardy, thrives well on a stove wall) and *A. athiopicum*. Most of the others, such as *A. formosum*, are too strong to harmonise well with the extreme delicacy and beauty of this little Grass-like Rush when grown in a high temperature; and this plant, grown in this way, is as useful as it is beautiful. Plants of it are also equally well suited for clothing conservatory walls, or for the back walls of corridors and passages; though in a low temperature they are not so exquisitely delicate as in a warm one. Portable temporary screens for drawing, sitting, or dining-room uses, might readily be formed of *Isolepis* and Ferns, or centre-pieces for the dining room; for the latter what, indeed, could exceed in freshness the slender *Isolepis*, floating on a crystal fountain, with a few silver cups of *Eucharis* resting upon or amongst it? For a small vase, too, what can match, in grace, a drooping veil of its slender foliage? And for clothing a wall in company with the Ferns I have named, the whole lit up here and there with an outjutting stone and patches of variegated *Lycopodiums*, the *Isolepis* has no equal. P.

On Monday last we visited the Victoria Park at Bath, the site of the forthcoming exhibition of the Royal Horticultural Society, and a more desirable position for a great show could hardly be desired. The park is well laid out and varied in surface, and contains an excellent selection of trees and shrubs very well named. The great show will take place on a large open lawn in the centre of the park. The large tent is already far advanced, the banks being turfed. A fine drive and roomy footways go all round the park towards its outer portion, making the ground altogether as convenient as it is beautiful.

NOTES OF THE WEEK.

— THE first volume of M. André Leroy's noble work on Apples has just been published. The second volume, completing the work, is to appear in July.

— WE learn that Mr. Robert Warner has been appointed by the Council of the Royal Horticultural Society to represent English horticulture at the forthcoming International Exhibition at Vienna.

— THE beautiful and rare large Dog's Tooth Violet (*Erythronium giganteum*) is now in flower in Mr. Barr's collection. All lovers of hardy plants will welcome one so handsome both in leaf and flower.

— PROBABLY the finest collection of Daffodils ever brought together is now to be seen at Mr. Barr's experimental grounds at Tooting. They are classified in such a manner as to make their study comparatively easy. In Mr. Parker's nursery at the same place there are also fine displays of hardy plants and spring flowers.

— PERHAPS the finest flowered plant of *Odontoglossum Hallii* ever seen is now in bloom in Messrs. Veitch's nurseries at Chelsea. The plant is large and vigorous, and has seven flower-spikes, one of which has no fewer than twenty flowers upon it, all large and perfectly developed.

— OF *Arpophyllum giganteum* an exceedingly fine specimen is now in bloom in the gardens of Lord Londesborough at Norbiton, Surrey. It has ten large well-developed flower spikes, around which the beautiful little rosy-purple shell-like blossoms are arranged with the greatest possible symmetry and beauty. This may be regarded as one of the best-bloomed plants in the country.

— AT the meeting of the Royal Horticultural Society, held on Wednesday last, a very useful flower-pot was shown by Mr. Matthews, of Weston-super-Mare. It was a pot of ordinary form, perforated around the rim, each perforation being about an inch and a half apart. By means of these perforations dwarf plants may be tied down to the rims of the pots in which they grow without the aid of stakes, thus at once securing neatness and freedom from injury sometimes inflicted on the roots by the use of stakes. A *Pelargonium* planted in one of these pots, and tied to the rim, was submitted for inspection, and clearly illustrated the advantages which these pots possess over those of the ordinary make.

— MR. McNAB recently made some remarks before the Botanical Society of Edinburgh, on the spiral Rush known as *Juncus effusus* var. *spiralis*. He said that during the meeting of the British Association—held at Edinburgh in 1871, the attention of some of the members was directed to this peculiar plant, which was originally found in the North of Ireland by the late David Bishop, while curator of the Belfast Botanic Garden. As far as he could recollect, only one plant of it was discovered, and it had been propagated ever since by division of the roots. On that occasion he was asked if the spiral form could be reproduced from seed, but he was then unable to answer the question. Although good seed was very sparingly produced he had some collected and sown, and he could now affirm that it could be thus produced, as all the seedlings raised were more or less spiral.

— THERE is a report current that Her Majesty and the Court have decided not to countenance what has taken place at South Kensington with reference to the Royal Horticultural Society, or to recognise the new council, until they have finally come to terms with the Exhibition Commissioners. It is said that a compromise is being negotiated, the effect of which, if it is successful, will be that while visitors to the Exhibition will have free access to the gardens on all ordinary occasions, admission to them on "show days" shall be only by payment of such sum as the society may think is calculated to keep the attendance select. Collaterally with this arrangement there will be modifications in the propositions of the Commissioners as regards the number of tickets of admission to the Exhibition to which the Fellows will be entitled, and also respecting the financial relations of the two bodies. Sir A. Slade has been provisionally appointed treasurer.

— WE extract the following account from the pages of a foreign journal, without, however, pretending to indorse its historical accuracy. "*Clianthus puniceus*, which now grows in great abundance in New Zealand, is said to be not a native of that country, but to have been originally introduced in the following manner. Many years ago a French ship, which touched at one of the islands, was seized by the natives, the crew massacred, and the cargo pillaged. Some boxes, which were brought ashore on a small island in the Kiri-Kiri River, when opened, were found to contain nothing but seeds. In their disappointment the plunderers scattered these about in all directions, and in a few years afterwards the whole islet was covered with the bright-red flowers of *Clianthus puniceus*. The natives, charmed with the colour, at once appropriated the flowers for purposes of personal decoration; and so popular did they become, that plants were con-

veyed to various parts of the mainland and carefully replanted, with a view to a more convenient and constant supply. Thus, in process of time, *Clianthus puniceus* became so widely distributed in New Zealand that it now presents all the appearance of being indigenous."

— WE are informed that the Royal Horticultural Society's show of *Chrysanthemums* will be held on November 12th and 13th, instead of, as has been announced, on the 5th and 6th of that month.

— ON Good Friday, notwithstanding the coldness of the weather, about 15,000 people visited Kew Gardens, and upwards of 35,000 paid them a visit on Easter Monday.

— MR. BORN informs us that he has a plant of *Magnolia conspicua* in his garden at Twickenham which has at present over 2,000 flowers on it. It is about 18 feet in height, and 12 feet in diameter, and is the admiration of all who see it.

— WE understand that a premium of 200 guineas is offered for the best design for laying out the Roundhay estate, Leeds; that 100 guineas are offered for the second best design, and that 50 guineas are offered for the third best. Part of the estate is to be laid out as a public park, and the remainder as sites for villa residences. Applications are to be made to Mr. Curwood, Town Hall, Leeds.

— FRENCH *Asparagus* from the open ground has now arrived in Covent Garden market. Its stalks, as a rule, are about an inch in diameter, and some of them measure even more than that. Our home-grown forced *Asparagus* has been excellent this season, but as yet we have seen no *Asparagus* at all comparable with that from France.

— THE finest Apple at present in Covent Garden market is the French Calville Blanc, which is of large size, and of a beautiful yellow colour, the specimens of it which we examined being in as good a state of preservation as when they were removed from the tree. The fact that they realise from twenty shillings to thirty shillings per dozen, testifies to their quality.

— THE Manley Hall Orchids were sold the other day by Messrs. Capes & Dunn, and realised large prices, of which the following are a few of the more remarkable:—

The magnificent specimen of *Cocos Weddelliana* figured in our columns a short time ago, was bought by Mr. Wm. Cole, for £60, a smaller plant fetching 42 guineas, while a splendid specimen of *Geonoma Seemannii* realised 31 guineas, and a plant of the rare and beautiful *Nepenthes sanguinea* fetched £50.

— WE regret to announce the death of Mr. Charles J. Perry, of The Cedars, Castle Bromwich, Birmingham, which took place on Good Friday, at the early age of fifty years. Mr. Perry commenced his horticultural career when only fifteen, and for more than thirty years has been a prominent exhibitor. His attention was first called to the *Dahlia*, of which he raised many first-class seedlings. Subsequently he engaged, with no less zeal and success, in the cultivation of the *Verbena*, many of the best varieties of which owe their existence to his practised skill and judgment. As a Rose grower he stood deservedly high, and was for many years a judge at our great metropolitan Rose shows. He was also a leading member of the Hands-worth Floral and Horticultural Society, filling the office of honorary secretary from the establishment to the dissolution of that body. By a large circle of acquaintances he was respected for his kind and genial disposition, while his sterling qualities inspired all who enjoyed his intimacy with feelings of the warmest regard. He was buried on Thursday last in the churchyard of Castle Bromwich.

## THE FLOWER GARDEN.

### THE PASQUE FLOWER.

Now—when the Pasque flower is pushing its purple blossoms up through the wind-beaten Grass, and when our gardens are brilliant with the beauty of the more common Anemones—is a seasonable time to call attention to the beauty of this lovely species. Though sparsely distributed in Britain, this fine old border plant is a true native, and when it does occur on a bleak chalk down, it is generally freely dotted over the turf. The position is usually such as to suggest the aptness of the name Windflower for the family generally; and there are few sights more interesting to the lover of spring flowers than to see its purple blooms just showing through the hard Grass of the blast-swept down on an early spring day. The plant is much smaller in a wild than in a cultivated state, usually devoting itself to the production of a solitary flower, which, while showing through the Grass, seems careful not to rise above it. In the garden it forms rich healthy tufts, and flowers more abundantly and vigorously, the contrasts between the wild and cultivated states of the plant being very marked. There are several varieties, including red, lilac, and white

The Pasque Flower (*Anemone Pulsatilla*).

kinds, but these are now rare. There is also a double variety. It prefers well-drained and light but deep soil. It is well suited for borders and also for the rock-garden.

### THE HYDRANGEA.

APART from its interest as a pot plant, the Hydrangea has considerable claims upon our attention as a shrubby border plant, and seen, as we sometimes find it, in favourable spots upon the sea-coast, it is certainly one of our most effective deciduous shrubs. In Devonshire and Cornwall, South Wales, more especially near Swansea, North Wales, Anglesey, and some other districts, we have frequently met with specimens of the Hydrangea growing in the open ground, huge bushes 6 and 8 feet in height, and quite as much in diameter, each producing scores, perhaps hundreds, of trusses of its gorgeous flowers, sometimes pink, and in other cases a soft cerulean blue. Where, indeed, a soil is strongly impregnated with iron, whether it be loam, peat, or sand, you may almost make sure of blue flowers being produced. The Hydrangea is a plant which, to grow it to perfection, does not need a compost, that is, there is nothing gained, but rather the contrary, by compounding a soil for it. I have spoken of loam, peat, and sand; the two former of these will suit the plant perfectly in the simple form, and, indeed, much better than when mixed together. For choice, however, I prefer a nice mellow loam, not too light, and in that, with occasional waterings of

liquid manure, the plant will grow in the most perfect manner. The fashionable soil, especially for producing blue flowers, when I practised near London, was the Norwood loam. That was rather strong, and parts of it full of red streaks of iron rust, but when broken down and exposed to the weather, for a few weeks it formed a fine potting soil, and one in which the plant delighted.

The Hydrangea may be very readily propagated by cuttings, and those which are taken from near the base form the best plants. My own rule used to be to put the first batch of plants into the forcing-house about Christmas time, and those, if the temperature was growing, gave some nice cuttings before the end of January. These were taken off when not exceeding an inch in length, and were put in propagating pots in the usual manner, the only precaution taken being to surround the base of the cutting with some sharp sand. The temperature of a Cucumber frame is the most suitable for striking this plant, always observing the good old rule never to allow the cuttings to droop until the roots are formed. Directly the cuttings are nicely rooted pot them off, using the soil you intend to continue; put them into small pots first, and when those are full of roots remove them to the size in which it is intended that the plant shall bloom. A few of the strongest may require 6-inch pots, but as a general rule the 4-inch size will be found sufficiently large for the first season. The temperature for the plants must be brisk, moist, and growing, and care should be taken that the plants be kept near the glass, so that they may make thick, starchy, healthy growth, the stem not being more than a few inches in height, and each leaf nearly as large as your hand. Ripen such a growth thoroughly, get the leading bud nearly as large as the end of your thumb by the time the leaves begin to fall in the autumn, and then you may make sure of a grand panicle of flowers the following season. To effect this kind of growth a frame or pit is most desirable, especially in the early part of the season, and where that cannot be secured put the plants upon a shelf near the glass, and as they are greedy feeders, place each pot in a feeding saucer so that water may be put in if necessary. When the growth is made, gradually inure the plants to the open air, so that by the end of May they may be set under a south wall to get thoroughly matured, and then be removed to a more shady situation to pass the season of rest. Keep the plants comparatively dry when the leaves begin to ripen and fall off, but do not attempt to force a premature ripening by withholding water before the plants give indication that the season of maturation has arrived. The best place to winter the plants will be a dry airy shelf, and but very little water will be necessary. This completes the first season's management. In the second year, if flowers are wanted early, say in April or May, forcing must commence at the end of December, and be continued in the temperature of the earlyinery until the flowers begin to show colour, when the plants may be removed to a cooler atmosphere. There is no advantage in potting the plants before they bloom, as they seldom make root in the fresh soil; but each pot may have a feeder containing water placed under it, which may be kept filled during the sunny hours of the day, but at night they will be better empty. When the plants break, reduce the side shoots to three or four of the best placed upon each plant, which may be grown on for future blooming, and the others may be used as cuttings. If particularly large individual flowers are required, thin out, directly they are fully recognisable, half the buds upon each truss, of course choosing the weakest and worst placed. The truss of a well-grown Hydrangea should be at the least a foot or more in diameter, and each flower should be nearly as large as a five-shilling piece. Thus grown, the Hydrangea, whether blue or pink, is a very imposing object, and will remain in perfection in the conservatory for two months. Directly the bloom becomes faded, cut the branch away to the secondary shoots, which are to form the blooming shoots for the following season. These must receive all the encouragement that can be given them, and for that purpose it will be necessary to shift the strongest plants into eight-inch pots, and the others into pots one size smaller. Use the same kind of soil, and, at the time of shifting, remove the crooks, and at the same time, with a pointed stick, loosen the matted roots around the ball, so as

to induce them to root into the fresh soil. Of course, after this shifting, the plants will require to be kept close and shaded until they make fresh roots, and then they must receive just the same encouragement they did in the first season. These plants, if properly grown and ripened, will, in the following season, produce three to four fine handsome trusses each, and then form very handsome subjects for vases. If it is desired to grow the plants a third year, the same process as to disbudding must be followed, and then a dozen shoots to each plant may be encouraged. I generally, after the second season's blooming, put the plants in the open ground, mixing them in the borders with the American plants, where in August and September they form very effective objects.

For early beds, in the dressed flower garden, the *Hydrangea* is very desirable. Plants started in January come into flower in April, and form very nice groups through May and June. For single specimens upon the lawn, in places where the wood ripens properly, the *Hydrangea* forms a very fine object; where it does not ripen, large specimens should be grown in pots or boxes, and be set out upon the terraces in the summer season. They form capital companion plants to the scarlet *Pelargoniums*. When grown in permanent beds, the soil should be porous and well drained, and should be raised considerably above the general level of the surrounding soil, *Hydrangea hortensis* and its variety, with the variegated foliage, are the kinds most generally grown, the latter, especially, for its foliage. A few plants of *H. japonica* may also be cultivated, but they are not so effective as the older species. Those who require blue flowers speedily may crush some alum into fine powder and put a pinch occasionally upon the surface of the soil. This will give blue flowers, but it will be at the expense of the health of the plant, which must be thrown away when it has done blooming. W. A.

#### NEW, RARE, OR NEGLECTED ALPINE PLANTS.

(Continued from p. 278.)

*ETHIONEMA GRANDIFLORUM*.—This is of larger and more sturdy habit than *E. saratile*, less spreading and prostrate in habit, less glaucous in tone, and with much larger flowers of a purplish rose colour, in elongated spikes. It is a valuable plant for the rock-garden, thriving freely in sandy loam, and exceedingly well suited for margins and slightly-elevated rocky banks. As a border plant, it will also thrive where the soil is free and well drained. Being somewhat impatient of transplantation, it is desirable to allow some plants to ripen seed on sunny edges or borders. Seedlings in pots will, of course, transplant easily. It deserves a place in every collection of alpine and herbaceous plants.

*ANDROSACE GLACIALIS*.—A rather rare and beautiful species, from Switzerland, growing in compact sheets, about 2 inches high, and bearing bright pink, or purplish rose-coloured, solitary flowers with a yellow throat and tube. The leaves are small, tongue-shaped, closely crowded, and forming small rosettes at the ends of the slender, red-tinged stems. Same treatment and positions as for *A. pubescens*.

*AQUILEGIA LEPTOCERAS LUTEA* (Yellow Long-spurred Columbine).—A new species from North America, and one of the finest perennials ever introduced. It grows in dense tufts, and produces a great abundance of large, golden-yellow, long-spurred flowers in a long succession of bloom, which commences in June. The flowers are much larger than those of *A.erulea*, and have long, straight horns or spurs. This species is not to be confounded with *A. arnea* of Reetzl, of which the flower is hardly half the size, and of a sulphur-yellow, shaded with green. Same culture and positions as for *A.erulea*.

*AQUILEGIA PYRENAICA* (Pyrenean Columbine).—A very dwarf species from the Pyrenees, 6 to 9 inches high, allied to *A. alpina*, but smaller in all its parts. It flowers early in summer, producing from 1 to 3 small blue flowers on each of the almost leafless stems. The leaves at the base are 1- or 2-ternate, with linear segments. It is a very suitable subject for rock-work, the margin of the mixed border, or for cultivation in pots, in moist sandy loam.

*ASTER REEVESI* (Reeves's Aster).—A very charming dwarf

*Aster*, with slender branching stems 9 to 12 inches high, and very small, linear, acute, Heath-like leaves. It flowers in autumn, producing a great abundance of small white yellow-centred blossoms in a dense pyramidal panicle. Well suited for rock-work or borders, in ordinary soil. N. America.

*ASTRAGALUS VAGINATUS* (Sheathed Astragalus).—A handsome species with erect pubescent stems, about one foot high. Flowers in summer, of a rosy-purple colour, with white-tipped wings, large (each flower about an inch long), and arranged in dense spikes on stalks longer than the leaves. The leaflets, which are usually in seven or eight pairs, with an odd one, are of an elongated-oblong shape, and covered on both sides with short, silvery, adpressed hairs. A native of Siberia and N. America, and a good plant for either rock-work or borders, in sandy loam.

*ASTRAGALUS ALPINUS* (Alpine Astragalus).—This plant, which is considered by some to be a variety of *A. Onobrychis* is a native of various parts of northern Europe and Siberia, and occasionally, though rarely, found in Britain. It is a prostrate hairy herb, with branching stems varying from a few inches to a foot in length, and producing, in summer, short racemes of bluish-purple (sometimes whitish), drooping flowers. The leaves consist of from eight to twelve pairs of ovate or oblong leaflets, with an odd one. Same positions and culture as for *A. Onobrychis*.

*BRYANTHUS BREWERI*.—A handsome dwarf shrub of compact habit, nearly a foot high, from the lofty sierras of California. The rigid ascending stem and branches are thickly covered with smooth linear leaves about half an inch long, and narrowly revolute at the margin. The flowers are half an inch across, cleft to, or rather beyond, the middle, of a bright rose-violet or red-purple colour, the upper part of the petals being of a darker shade. The beauty of the flowers is enhanced by the great length of their ten light-coloured stamens, tipped with violet anthers. The inflorescence is at first in dense roundish clusters at the ends of the erect branches, becoming corymbose as the flowering advances. This is a valuable addition to the rock-work or choice border, and should be planted in sandy peat soil.

*CAMPANULA RAINERI* (Rainer's Campanula).—An exceedingly dwarf, pretty, and rare species from the mountains of Styria and Carinthia. It blooms early in summer, producing erect, light purplish-blue, funnel-shaped flowers, over an inch across, on stems 1 to 2 inches high, each stem bearing from one to three flowers, and issuing from a rosette of small, roundish, hairy leaves. This is one of the most interesting Campanulas in cultivation, and admirably suited for warm ledges of rock-work, or the margin of the choice mixed border, where its creeping roots will spread rapidly in fine sandy soil.

*CAMPANULA WANNERI* (Wanner's Campanula).—A distinct and handsome species, 6 to 10 inches high, with drooping, dark-blue, tubular, bell-shaped flowers, each  $1\frac{1}{2}$  inch long, appearing in May on long one-flowered axillary and terminal peduncles. Leaves lance-shaped, unequally toothed, the lower ones decurrent on long leaf-stalks. A native of Transylvania and the Banat Alps. At present it is rather scarce, and until more plentiful should be confined to the rock-work; but it will probably prove an excellent border plant. Ordinary free or sandy soil.

*CROCUS IMPERATI* (Imperati's Crocus).—A very early spring-blooming species, nearly allied to *C. versicolor*, but much handsomer, 3 to 6 inches high. The flowers are sweet-scented, of a lilac-purple on the inside, while the outside is of a creamy-white, marked with three longitudinal dark-purple lines, of which the two outer ones and the end of the middle one are curiously feathered or fringed with short lines of the same colour. This very charming Crocus was found on the mountains of Calabria, in Southern Italy, at an altitude of from 3,000 to 6,000 feet.

We may here mention also another fine species of recent introduction from the mountains of Greece, viz., *Crocus Aucheri*, a dwarf, very early spring-flowering species, with deep orange-yellow flowers. (Syn. *C. chrysanthus*).

*CROCUS BORYANUS* (White Autumn Crocus).—A very pretty autumn-flowering kind, from Asia Minor, the Morea, and the Greek Islands. The flowers, which do not appear until late in autumn, are of a creamy-white, with an orange-yellow throat,

the base of the segments sometimes marked externally with dull purple lines. This species, which is as yet rare in gardens, is a very pleasing addition to the list of our autumn-flowering plants.

**CYANANTHUS LOBATUS** (Lobed-leaved Cyananthus).—A brilliant and remarkable Himalayan rock-plant, spreading loosely about, with prostrate habit and procumbent or ascending stems about 4 inches high. The flowers, which appear in August and September, are purplish-blue, with a whitish centre, solitary, usually terminal, about an inch across, funnel-shaped, with five spoon-shaped lobes, and are finely fringed on the throat with numerous long, soft, whitish hairs. The leaves are lozenge-shaped, small, fleshy, alternate, deeply and irregularly lobed, greyish underneath. The best position for this plant is on a sunny ledge of rock-work, where its overhanging flower-laden stems will produce a fine effect. It grows best in a mixture of sandy peat and leaf-mould, with plenty of moisture during the growing season. It is easily and freely increased by cuttings. The seed requires a dry favourable season to ripen it; in wet weather the large, erect, persistent calyx becomes filled with water, which remains and rots the included seed-vessel.

**CYPRIPEDIUM GUTTATUM** (Spotted Lady's Slipper).—A very charming Siberian species, which has been described as "one of the most beautiful of vegetable productions," although at present seldom seen in gardens. It grows from 6 to 9 inches high, and flowers in June, producing solitary, rather small but beautiful snow-white flowers, heavily blotched or marbled with deep rosy-purple. The flower-stem rises from a single pair of broadly-ovate downy leaves. It requires a shady position on the rock-work or mixed border, in leaf-mould, moss, and sand, and should be kept rather dry in winter.

**DAPHNE RUPESTRIS** (Rock Daphne).—A neat and diminutive shrub with shining and fleshy spoon-shaped leaves, from a third to one-half an inch long, channeled above, and with a conspicuous and large blunt keel below, the spaces between the keel and margins being of a greyish tone. Flowers somewhat like those of *Daphne indica*, and very sweet-scented, appearing in early spring. New Zealand. (Syn. *Gaultheria rupestris*).

**DRABA GLACIALIS** (Glacier Draba).—A very dwarf species, forming dense little cushions 1 to 2 inches high, which in April are covered with bright golden-yellow flowers. Leaves linear, smooth, ciliated, forming small rosettes closely packed in pineushion-like masses. The plant very much resembles a small specimen of *D. aizoides*, and is considered by Koch to be merely a variety of that species, growing at a higher elevation; but it differs from it by having a few-flowered stem, pedicels shorter than the pod, and a short style. It is found on the granitic Alps of Switzerland, and is suited for exposed spots in the rock-garden, in moist and very gritty or sandy soil, and associated with the dwarfiest alpine plants.

(To be continued.)

## LILIES.

THESE noble plants share the fate of a great many valuable hardy subjects, inasmuch as they are rarely so placed that their beauty may be fully seen, or so planted that they may be developed in all their vigour. Not unfrequently hardy species are grown in pots, and suffer annual repotting, and it may be annual drying, than which nothing can be more injurious to them. The annual tearing up of the roots consequent on repotting Lilies is also exceedingly injurious, and the plants subjected to it rarely make a first-rate growth. Then, again, in borders they are frequently planted where any but the common kinds have little chance of thriving; for it should be generally known that some of the very finest Lilies, as *L. superbum* of North America, only succeed perfectly in peat soil; hence we frequently see this and other species in such a starved state, never yielding a bloom, that the owner asks himself how such a poor object ever came to earn such a fine name. Now, among the various ways of growing and enjoying Lilies, there is one practicable by almost every owner of a garden, and which leads directly to the best results both from a cultural and æsthetic point of view. The culture of Rhododendrons has for so many years been so popular in this country that there are few places that do not possess beds or masses of them, or in which fertile masses of peaty soil have not been gathered for their reception. The Rhododendron bush, however

fine in flower, has at all times a flattish, formal outline, and this is often disagreeably apparent where large masses are planted, as is now the custom in many places. The soil suited to the Rhododendron is also perfectly suited to the Lily race. The bold and tall heads of Lilies standing above the flat green of the Rhododendrons in summer, sometimes, as in *L. tigrinum Fortunei* and *L. superbum*, in magnificent candelabra-like heads, are the very things to relieve these masses in the most effective way. Then, again, the Lilies themselves will be seen to much greater advantage; the bases of their stems being hidden by their surroundings when withering will not be an eyesore, as they often are when in a border, so that an impatient gardener might want to cut them down before their time, or have something else in their place. The conclusion is plain enough. There is no better plan with Lilies than dotting them here and there through the Rhododendron beds, and leaving them there undisturbed from year to year. Here, untortured by the repotting process, and their scaly and therefore easily dried roots not exposed to drought at any time, they would spread into vigorous tufts that would be magnificent when in bloom. It would not be desirable to dot them all over the beds; a distinct species here and there is what is required. When kinds are rare, a single root will suffice to begin with; it will soon increase in the congenial soil. The very open spaces which long remain between Rhododendrons, &c., in consequence of their somewhat compact and slow-growing habit, encourage the kind of arrangement suggested. Dwarf kinds, like *L. longiflorum*, should of course not be placed among the Rhododendrons, but on the fringes of the beds and clumps. It would be desirable to treat other fine bulbs in this way as well as the Lilies, as, for instance, the Gladioli, *Sparaxis pulcherrima*, *Tritomas*, *Tritonia aurea*, &c., none of which need be disturbed after being planted. Another advantage of this mode is the succession of bloom from the same surface. As a rule, once the blush of early summer bloom has passed from the American plants, they present an uninviting surface for the season afterwards; whereas varied in the way described, the beds would be most attractive at other seasons.

**Hepaticas.**—How is it that these are so seldom found in gardens, seeing that they rank among the best of spring flowers? Now-a-days they seem almost wholly confined to cottage gardens, where now and then a good bunch or two of the old double red may be found, and occasionally a plant or two of the single blue. I find all the varieties I have to be equally hardy, and to do equally well if grown in a good deep loam, as the roots go straight down into it in search of food and moisture. Hepaticas are rather impatient of removal, an operation which, although at times absolutely necessary for purposes of propagation, should be performed as seldom as possible. I am growing now seven distinct kinds, namely, double and single red, double and single dark blue, single light blue, single white, and a kind called *H. angulosa*, the light blue flowers of which are single and larger than those of the old light blue sort, and the leaves are also larger and more rounded than in other kinds. As Hepaticas all flower at the same time, a pleasing mode of arranging them in borders is to plant them in triangles of three colours.—A. D.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Viola odorata cœrulea.**—This desirable variety, of which I send you some flowers, I found in a Derbyshire lane. It is desirable from its bluer colour than that of the ordinary kind.—H. HARPER CREWE.

**Large-flowered Single Larkspur.**—Is there such a thing in the wild world as *Delphinium grandiflorum, single*? If so, has any one seen it, or does any one possess it? Or are we to suppose that the dense double flower, known as "*D. grandiflorum plenum*," is the originally wild form of Siberia? If it be the wild type, is any parallel case on record?—NAMELESS.

**The Polyanthus from Seed.**—In THE GARDEN (p. 256), "R. D." has an article on the Polyanthus, and speaks of the seedlings not flowering until the second year; in this I think he is wrong. In the year 1871 I bought a packet of seed from Messrs. Sutton; it was sown in August, and last year the seedlings flowered, and proved to be a fine strain of gold laced Polyanthus. As soon as their seed was ripe it was sown in shallow pans in a cool frame; when the plants from it were large enough to handle, they were put into separate pots, and last week my gardener put out 14 dozen seedling Polyanthus all showing spikes of flower.—H. M. L., *Coccutry*.

**Roses for Button-Holes.**—Will you kindly give me a few names of Roses suitable for forcing for button-holes, and oblige QUEEN OF FLOWERS. [The sorts best suited for button-holes are those of which the back of the petals is clear in colour as well as the upper surface. The best, according to Mr. George Paul, are: H. P.: Abel Grand, Beauty of Waltham, Duke of Edinburgh, Duke of Wellington, Fisher Holmes, General Jacqueminot, Henri Ledebaux, Jules Margottin, Louise Wood, Madame Victor Verdier, Virginalde, Monsieur Noman, Princess Mary of Cambridge, Vicomte Vigier, Victor Verdier. Bourbon: Souvenir de la Malmaison. Tea: Abricot, Alba rosea, Catherine Marnet, Douvenis, Goubault, Isabella Sprunt, La Nante, Madame Falcot, de Charles, Nauvin, Safran.]

## ANCIENT EMPLOYMENT OF FLOWERS.

(Concluded from page 286.)

THE employment of evergreen boughs for the ancient altars is mentioned in many places in classical literature, and cannot but recall the strewing of the "branches of Palms" upon an occasion in Jerusalem when the symbol of honour and glory was eminently appropriate. Nothing more or less than memorials of these ancient practices are our own current ones, destined probably to endure for ever, of decorating places of worship at Christmas-time with Holly, and Laurel, and Fir; and again at Easter and Whitsuntide with flowers; though with Christians there is involved in the former custom the additional and enriching idea of Life triumphing over death, or, what comes to the same thing, the victory achieved in Palestine over evil and sin; old England's indomitable Holly in particular, laughing, as it were, to scorn, the cold, the snow, and the frost. The various evergreens employed by the ancients for sacred purposes went by the collective name of *Verbena*, the parent form of our English "vervain," the appellation of *Verbena officinalis*, given to the wayside weed, resting upon some vague belief that it was one of the plants used in the temples. How curious that by the middle of the nineteenth century, a name once of significance so reverend and exact, should be best known in connection with a scarlet-flowered herb from the Brazils! Botanically the change is right enough, but it is almost to be regretted that in the process of shifting names, "*Verbena*" could not have been reserved for the fragrant shrub which is now the *Aloysia citriodora*, though the classical appellation will no doubt cling to it, among the lovers of perfumes, as long as delightful odours remain sources of pleasure. The allusions to *Verbena* in ancient poetry are numerous and often very elegant. *Medea* encompassed her altar with a *Verbena* wreath when preparing to give youth again to *Æson*\*; the priests wore chaplets of it on the morning of the death of *Æneas*†; carried by an ambassador it rendered his person inviolable; suppliants also bore *Verbena*; and being specially valuable in all magical operations, the name appears in the famous list of spells in the eighth *Eclogue*‡. Pleasant is it to observe that just this kind of collective denomination is in use to-day, for we need only visit the market-place on December 24th to find the Holly, the Mistletoe, the Arbutus, Pine, Laurel, and Fir all selling under the name of "Christmas," which, so employed, is literally the representative of the ancient "*Verbena*."

Whether flowers of any kind, in addition to green foliage, were comprised in the name "*Verbena*" is not clear; but there is reason to believe that Roses, at all events, were mingled with the sacred branches, and placed upon the altars—whatever flowers were used probably having special consecration, after the manner in which the *Madonna Lily*—so charming a feature in all early Christian art—is devoted in certain countries to the *Virgin Mary*.

FLOWERS UPON GRAVES.—Primarily derived from the practice of dedicating particular trees and shrubs to the deities, was the custom, equally ancient, of planting and strewing flowers and foliage upon graves and tombs. People are so accustomed to associate practices of this description with Christian creeds, and the civilised sentiment of western Europe, that the profound antiquity which really pertains to them is quite lost sight of. It compares with the history of the Ferns, which are ordinarily taken just as a part of the garniture of the earth's surface, a something coeval only with mankind, whereas their dynasty is one of the most venerable our planet has witnessed. There is no need to adduce many examples. Sufficient proof is supplied in that beautiful line in the "*Electra* of *Sophocles*," (B. C. 440) where *Chrysothemis* describes her father's tomb as "garlanded around with every flower that grows" (895-6). Authors upon the subject say that "the Greeks considered all purple and white flowers as sacred to the dead, and that the Thessalians strewed the grave of *Achilles* with the immortal *Amaranth* and *Lilies*.§ The tomb of *Sophocles* himself was embellished with *Roses* and *Ivy*, as shown by the celebrated epitaph ascribed to *Simonides*, that glorious old poet, who at eighty could still command a prize. *Ivy*, too, and flowers were planted round the grave of

*Anacreon*; while in the whole of *Virgil* there is no passage more tender, pathetic, and natural than that which describes the preparation of the bier of the unfortunate *Pallas*, constructed of *Oak* and branches, the youth himself being likened to a flower gathered prematurely by the hand of a girl.

Qualem virgineo demessum pollice florem,  
Sen mollis viola, seu languenti hyacinthi,  
Cui neque fulgor adhuc, nec dum sua forma recessit!

So that if there were "nothing new under the sun" in the days when the Proverbs were written, still less can we find novel in the usages of to-day. The actual beginnings of things are very seldom near at hand, while many are only the last, the newest, and the best expression of something that dates back to *Mr. Gladstone's Jucundus Mundi*.

In *Rome*, in ancient times, the Greek fondness for crowns and garlands constructed of flowers was carried to a far greater length, and, like most of the usages which the Romans adopted from eastern, and especially from conquered countries, became degenerate. So excessive at last was the passion for ornaments of this description, that the wearing of them was forbidden by law, except by privileged individuals, and these were in some cases very special and honorary. The civic garland, made of *Oak* leaves, was given, for instance, to men who had rescued a fellow citizen in a combat with the enemy. *Cicero* reproached the pro-prætor *Verres* with having made the tour of *Sicily*, wearing a crown of flowers upon his head, and a chaplet upon his back, while the couch or litter in which he was carried was strewn with *Roses*. *Roses* were used decoratively at banquets with the utmost extravagance. *Plutarch* relating of *Cleopatra* that she used upon one occasion no less than £200 worth; while for instances of prodigality in the use of flowers in general, we need only refer to the pages of *Catullus*. Extremes produce extremes, and after the downfall of the Roman empire we hear no more of flowers and chaplets for a thousand years.

It is necessary here only to add that in ancient *Rome* the manufacturers of the chaplets so much in favour were called *coronarii*, from which arose the practice in a later age, of applying the epithet *coronarius* to flowers suitable for crowns, and eventually to any others that were noted for their beauty or fragrance. Examples occur in the well-known specific names of certain familiar and old-fashioned species of *Anemone*, *Philadelphus*, *Agrostemma*, *Hedysarum*, &c. The final tradition of the ancient flower-crown is found in the name of *Carnation*, which word is an abridgement of the older form "coronation," as employed by *Spenser*, and also by *Lyte*, in his "*Niewe Herbal*," A.D. 1568. A lady seated, and sorting flowers for use in a chaplet, gave occasion to one of the most famous pictures of antiquity, the painter of which, *Pausias*, contemporary of *Apelles*, in the time of *Alexander the Great*, is said to have been the first who attempted flower-painting. The picture in question was called *Stephanoplocos*, or the "Chaplet-maker," and found a purchaser in the renowned but voluptuous *Lucullus*.

LEO GRINDON.

## SPRING.

The sun is warm, the sky is blue,  
The buds are full, the Grass is growing;  
I wonder if the signs are true,  
And winter really is going!  
'Tis too good news, it seems to me,  
That gentle Spring at last is coming.  
This very morn I saw a bee—

But he was humming!

The seeds don't seem to show as yet—  
I fear they've rotted altogether;  
The winter's been so very wet—  
But shall we have more settled weather?  
Those fleecy clouds, on high that wing,  
Can weep like *Niobe's* sad daughters;  
And we perchance may find the Spring  
A spring of waters.

Oh, gentle Spring! betray us not,  
We can be dry, and yet bilious;  
And, pray, give back the watering-pot  
To *January's* old *Aquarius*;  
Where'er your tiny foot shall touch,  
Bid blossoms spring, the greensward fretting—  
For we've an appetite for such,  
That needs no whetting. —Fun.

### THE BEAUTIFUL IN GROUND-SURFACE.

ARTISTS and men of taste have agreed that all forms of acknowledged beauty are composed of curved lines. The principle applies as well to the surface of the earth as to other objects. The most beautiful shape in ground is that where one undulation melts gradually and invisibly into another. Every one who has observed scenery where the fore-ground has been remarkable for beauty must have been struck by this prevalence of curved lines; and every landscape gardener well knows that no grassy surface is so captivating to the eye as one where these gentle swells and undulations rise and melt away gradually into one another. Some poet, happy in his fancy, has called such bits of grassy slopes and swells "earth's smiles;" and when the effect of the beauty and form of outline is heightened by the pleasing gradation of light and shade, caused by the sun's light variously reflected by such undulations of lawn, the simile seems strikingly appropriate. Though there is no positive beauty in a straight or level line, it is often interesting as expressive of power, and we feel as much awed by the boundless prairie or desert, as by

worse, is the fancy many persons have of terracing every piece of sloping ground—as a mere matter of ornament—where no terrace is needed. It may be safely said, that a terrace is always ugly, unless it is on a large scale, and is treated with dignity, so as to become part of the building itself, or to be supposed, more properly, to belong to it than to the grounds—like the fine architectural terraces which surround the old English mansions. But little gardens, thrown up into terraces, are devoid of all beauty whatever,—though they may be rendered more useful or available in this way. The surface of ground is rarely ugly in a state of nature, because all nature leans to the beautiful; and the ceaseless action of the elements goes continually to soften and wear away the harshness and violence of surface. What cannot be softened is hidden and rounded by means of foliage trees, and shrubs, and creeping vines, and so the tendency to the curve is always greater and greater. But man often forms ugly surfaces of ground, breaking up all natural curves without recognizing their expression, by distributing lumps of earth here and there, by grading levels in the midst of undulations,

Weeping Beech in St. John's Nursery, Worcester.

the lofty snow-capped hill. On a smaller scale, a level surface is sometimes agreeable in the midst of a rude and wild country, by way of contrast, as a small level garden in the Alps will sometimes attract us, that would be passed by unnoticed in the midst of a flat and cultivated country. Hence, as there are a thousand men who value power, where there is one who can feel beauty, we see all ignorant persons who set about embellishing their pleasure-grounds, or even the site for a home, immediately commence levelling the surface. Once brought to the level, improvement can go no further, according to their views, since to subjugate or level is the whole aim of man's ambition. Once levelled you may give to ground, or even to a whole landscape, according to the theory, as much beauty as you like; it is only a question of expense. This is a fearful fallacy, however;—fearful oftentimes both to the eye and purse. It is not less fearful to see a fine varied outline of ground utterly spoiled by being graded for the mansion and its surrounding lawn, at an expense which would have curved all the walks, and filled the ground with the finest trees and shrubs, if the surface had been left nearly, or quite as nature formed it. Not much better, or even far

and raising mounds on perfectly smooth surfaces; in short, by regarding only the little he wishes to do in his folly, and not studying the larger part that nature has already done in her wisdom.—*A. J. Downing.*

**An Indian Chief on Vegetarianism.**—"Do you not see that the whites live on corn, but we live on flesh? that the flesh requires thirty moons to grow, and is often scarce? that every one of the wonderful seeds which they scatter on the soil returns them more than an hundredfold? that the flesh has four legs to run away, and we only two to catch it? that the seeds remain and grow where the white man sows them? that winter, which for us is the season of laborious hunts, is to them a time of rest? It is for these reasons that they live longer than we do. I say, then, to every one who hears me, before the trees above our huts shall have died of age, before the Maples of the valley cease to yield us sugar, the race of the sowers of corn will have extirpated the race of flesh-eaters, unless the hunters resolve also to sow."

## THE KITCHEN GARDEN.

### GOOD KING HENRY.

We would particularly recommend to our readers, as a first-class vegetable for early spring use, the Good King Henry (*Chenopodium Bonus Henricus*), or English Mercury. This is, in many parts of England, Scotland, and Ireland, a rather common roadside weed, with a thick fleshy root, like that of a Dock, and grows to a considerable height. The lower leaves resemble those of Spinach, and are of a broadly triangular shape, often more than 3 inches long, stalked, sinuate or slightly toothed, rather thick and fleshy, and of a dark green colour. The upper ones are smaller and nearly sessile. It is extensively grown by the Lincolnshire farmers, almost every garden having its bed, which, if placed in a warm corner and well manured, yields an abundant supply of delicious vegetables a fortnight or three weeks before the Asparagus comes in, and for some weeks afterwards. From a south border we generally commence cutting the Mercury early in April, and continue cutting until the end of June. Some of our friends say they like it better than Asparagus; but we cannot go that length, though we like it very much. When properly grown, the young shoots should be almost as thick as the little finger, and, in gathering, it should be cut under the ground something the same as Asparagus. In preparing it for use, if the outer skin or bark has become tough, strip it off from the bottom upwards, and then wash and tie it in bunches like Asparagus. It is best boiled in plenty of water, with a handful of salt added. When tender, strain and serve simply, or upon a toast. Some have melted butter with it, others eat it simply with the gravy of the meat. Now, in cultivation, the Mercury will grow anywhere; but, to have it in the best form, superior cultivation is necessary. To this end you cannot have the ground too deep nor too rich. Hence we should say trench the ground 2 feet deep, mixing in an abundance of rich manure, and plant as early in the spring as possible. As the plant is a perennial, it is necessary to get an abundant yield of shoots, and to get them as strong as possible—and hence, in time, each plant may be a foot or more in diameter. In planting, we generally put the rows 18 inches apart, and the plants 1 foot apart in the row; and, after we begin to cut, we drench the ground frequently with manure water, or sprinkle the ground with guano in showery weather. Of course the plants must not be cut too severely until they are thoroughly established—say in the third year—and then you can scarcely injure them.

A.

### HOME-RAISED POTATOES.

(LATE SORTS.)

I now propose to take a survey of the sorts of Potatoes commonly known as late kinds, *ie.*, those that ripen late, and that, under good storage arrangements, keep sound and good until new Potatoes come in to take their place. In the first place, I will notice the best varieties raised and sent out by Paterson, of Dundee, who has deserved well of his country for his efforts to produce a robust, healthy race of Potatoes; and in that he has been eminently successful, although, like too many enterprising men, he has gained more honour than profit. The Dundee varieties are all characterised by an exceedingly robust haulm, that amounts in many of them to coarseness; and the majority are better adapted for field culture, where they can be planted in rows 2½ feet apart, than for gardens, where space is limited and the whole of it has to be effectually utilised. Paterson is now offering a new early white kidney, that resembles our Ashleaf, but is not so early; a new early red kidney, that inclines to be large and yellow fleshed, but is scarcely early enough for our southern notions; and two large round kinds, *viz.*, Zebra, a second early, having purple stripes on the skin; and Early Perfection, a second early of the Regent type and a good cropper, that promises to make a good London market Potato. The new White Kidney (not the early one) is a type of the Dawes' Matchless section, long and flat, but probably not superior to that old variety. New Blue Kidney is rather an elongated roundish-shaped one, somewhat coarse in appearance, but evidently a great cropper. And last, but not least, is a batch

of "Royal" rounds, with white, red, and purple skins, including the popular Victoria, Albert, Alexandra, British Queen, and Princess of Lorne, all of which are strong growers, large croppers, having white flesh, and they are also late keepers. The reason why so few of Paterson's Potatoes are cultivated in the south, is probably due to the fact that Dundee is too far north for purchasing small quantities to be profitable. Still, out of a dozen of Paterson's kinds, some certainly will prove established favourites, and eventually repay the first cost, which I can testify, as last year I grew them all, and intend giving them a better trial this year again. Our latest kidneys, and without doubt our best keepers, are the Lapstone race, of which I could mention at least a dozen named kinds, all of which are of the Lapstone family.

There is much talk and writing, especially at the times when the disease is prevalent, about the degeneracy of the Potato; but in such I have no reliance, for I have grown for several years a stock of the true original Cobbler's Lapstone, sent out some two-and-twenty years ago, and it is still as good, in every sense, as any of its more youthful competitors. One of the best of the Lapstones is Yorkshire Hero, a remarkably dry, mealy tuber, of great excellence, and a famous keeper; but if I mention at once such as Pebble White, Headley's Nonpareil, Daintree's Kidney, Brixton Pippin, Troughton's Incomparable, and Preston Prizetaker, it becomes evident that of the Lapstone family all are good, and yield a produce that will satisfy the most fastidious. Of late red kidneys that are in much request for exhibition purposes, I recommend Red Fluke and Cottager's Red Kidney, the latter being an enormous cropper, rather yellow fleshed, but a capital tuber for eating, and a grand help to the cottager if he has as many sacks of them in his store as he usually has of heads in his family.

Amongst round late kinds, I can recommend none more heartily than Purple Regent, an excellent keeping sort. The skin is thin, and the flesh almost as white as snow; and being a good cropper it stands in the foremost rank amongst our most useful table Potatoes. Wellington has somewhat flattened, roundish tubers, and red blotched eyes; and the Red Breadfruit is an entirely red form of this variety, but it seems to be a rather better cropper. Both of these have short, spreading haulms, and do not require so much growing space as coarser kinds, and they are also useful sorts for exhibition.

It will be evident that in a short *resumé* of this character, it is impossible to mention all those kinds that have been known amongst growers for some years past; for their name is legion. I have rather been desirous of showing that we have some cause at home to congratulate ourselves that the raising of Potatoes has not been neglected, and that we are now in the possession of sorts that cannot be excelled elsewhere.

A. D.

**Snowflake Potato.**—In reply to Mr. Gilbert's inquiry respecting this Potato (see page 238), I beg to say that I have a seedling under that name which obtained a first prize at Messrs. Suttons' root show in November last; and a similar prize was also awarded to my seedling red kidney, named Oxfordshire Hero. I agree with Mr. Gilbert's opinion as to the beauty of the Climax Potato. I had some of it on poor loamy soil last year, and they were very handsome. First prizes were awarded them in the class of round second earlies at Oxford, Banbury, and Chipping Norton. They were much admired in the first collection of eight varieties at Moreton, and also at the Royal Horticultural Exhibition at South Kensington in November last.—JAMES BETTERIDGE, *Chipping Norton*.

### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**New Tomato.**—American growers of Tomatoes highly recommend Hathaway's Excelsior as one of the most valuable varieties, if not the most so, of all those at present in cultivation.

**Rhubarb.**—I have cultivated this for many years, and have grown, I may say, most of the new and old varieties of this esculent. But the best, both for forcing, productiveness, and flavour is Hawk's Champion, presented to me by my old and much respected master, Mr. W. Myatt, of Deptford.—R. GILBERT.

**The Best Potatoes.**—Last year I grew in the gardens here about forty varieties of Potatoes, including all the leading American kinds, besides a selection of English sorts, and I find the following three to be all that can be desired for their respective seasons, *viz.*: Royal Ashleaf, Coldstream, and the old Lapstone Kidney. The last named I have found to be still the very best of all late Potatoes, handsome in shape, good in quality, and if grown in well-worked rich soil, the best of all late croppers.—R. GILBERT, *Burghley*.

## THE INDOOR GARDEN.

### MELASTOMA MALABATHRICA.

This is an easily grown plant, and one which, if well attended to, makes a good bush; it even produces fine heads of blueish-purple flowers when not more than from 1 to 2 feet in height. Cuttings of it strike freely in bottom-heat under bell-glasses. Its foliage is of a purplish-green, very hairy, and contrasts well with that of its associates in a mixed stove. This species of *Melastoma* is very common in Malabar, where it is used much in the same way as the common Laurel is with us. It is therefore called the Malabar Laurel. Some of the *Melastomads* are con-

*Melastoma malabathrica.*

sidered difficult to grow, but this one grows as freely as a *Pelargonium*. It likes a soil consisting of equal parts of loam and peat, to which should be added a dash of sand.

J. CROUCHER.

### LISIANTHUS RUSSELLIANUS.

BY T. BAINES, SOUTHGATE.

A SHORT time since, a correspondent who signed himself "One of the Old School," gave his recent experience with this *Lisianthus*. Some years ago I had to give that attention to the cultivation of plants which I had previously bestowed upon the more indispensable departments of fruit and vegetables, and I then felt inclined to try my hand on anything that had the character of being difficult to grow; I soon found out, however, that mere rule of thumb culture, let it be ever so carefully carried out, was more likely to lead to failure than success, and I at once saw that without some knowledge of the physiology of the different subjects with which I had to deal, success was a mere matter of chance. This is an axiom applicable as regards even the cultivation of plants of the commonest description; but in the case of plants difficult to grow, such knowledge is indispensable, a remark which holds good to matters relating to fruit culture as well as that of plants. I have seen men who have grown

as fine fruit, especially Grapes, as ever were cut from Vines, under certain conditions in one locality, entirely fail in another, though the same rule of thumb practice was carried out with most scrupulous exactitude; and the same remark applies with equal force to the plant under consideration, the culture of which requires intelligent management.

In April I obtained a packet of seed of it. I took a 12-inch seed-pan and well drained and filled it to within an inch of the rim with finely-sifted peat, containing a liberal admixture of sand and a little leaf-mould. On this I put a thin layer of sand, and gave the whole a good watering, to close up all interstices. This is essential; otherwise, as the seed is very small, it is liable, in subsequent waterings, to get washed down too deep to germinate. I then placed the pan in a stove near the light, but where the sun could not shine upon it, as the less water given until the plants are up the better. When the plants first make their appearance they are very small, and must be watered with care, or they will be washed out of the soil. They should be kept close to the glass, but shaded with a piece of tissue paper, for an hour's exposure to the direct rays of the sun will kill them. As soon as they were large enough to handle, I potted them in thumb-pots, using soil similar to that in which they were sown. During the summer I kept them in a stove close to the glass. I always shaded them, however, when the sun was shining, but never when it was not. As soon as they had made three pairs of leaves I pinched out the point, which induced them to push several shoots from the base. I repotted them into 4-inch pots, and never allowed the soil to become dry, for if they flag they die. If thrips exist in the house, they will attack them, more especially the little yellow one, that infests Orchids and *Allamandas*. *Lisianthus*es do not like smoking; I therefore dip them in tobacco-water, just sufficiently strong to kill the insects. About the end of September I place them on a shelf where they can stand within a foot or so of the glass, during the winter in the lightest place in a house the temperature of which is about 50° in the night. I set them in saucers on a few pebbles, and all the water which they receive during the winter, is applied to them in the saucers, as, if ever the surface soil about the collar of the plants gets wet in winter the plants damp off. About the middle of March they begin to push, and then I pot them into 12 or 15-inch pots well drained, using the same description of soil as before, but in a rougher and more lumpy state. I place five of the plants together in the middle of the pot, and water gently. I then set them in the stove close to the glass in a night temperature of 70°, with 10° or 15° of a rise by day in sunny weather, but I still shade them. They now grow apace, and there is no danger of damping if they are kept near the glass; but if they are plunged in the tan in a pit at the ordinary distance from the glass they all damp off in a week. When they have grown about 10 inches high, I stop all the leading points, an operation which induces them to break at every joint. I tie the shoots out regularly, and by the beginning of July they are in bloom, and keep flowering for a month or six weeks.

From a plant treated as has just been described, I have had 700 lovely flowers in one season. As soon as the seed is ripe, I gather it and throw the plants away. I never was able to keep a plant that had flowered through the winter. From the day they make their first appearance in the seed-pan until they have finished flowering, I never allow them for ever so short a time to be exposed unshaded to the sun. I never fumigate them, but keep them clear from insects by the use of tobacco-water. I always keep them as near the glass as possible, and I never allow them to become dry at the extremities of their roots; but in the winter I keep the surface soil about the collar of the plants dry, as otherwise they are almost sure to damp off. This and other plants of a similarly delicate character are fitting subjects for young gardeners to try their hands at, as the unremitting attention and close observation necessary to ensure success are eminently calculated to habituate them to exercise these most essential elements to success in other directions. The reason why this and numerous other plants are not so often met with as they used to be is obvious. Nowadays unlimited numbers of plants are required for indoor decoration, and for the production of quantities of

cut flowers. This and many other old-fashioned plants are not so well calculated for these purposes as are some others, and consequently they have given way to such things as are found to answer best.

### IRON FLOWER POTS AND VASES.

MR. BUCHANAN, a Scotch gardener, long settled in New York, and now one of the leading florists there, makes the following interesting remarks on this subject in a recent number of the *Agriculturist*. It may be as well to say that, from personal acquaintance with Mr. Buchanan, we know him to be an excellent cultivator, and that he has a large business in furnishing vases, &c., in the most fashionable part of New York:—

I believe that no material for pots is so conducive to the well-being of plants as iron. My attention was first directed to the subject by noticing the luxuriant and healthy growth of plants grown in iron vases, fully exposed to the sun even in our very hottest weather. Plants grown in marble and stone vases are as nothing in comparison with those in vases made of iron. I can only account for this difference from the fact that iron is the better conductor, and thus supplies a bottom heat to the plants. I have pots made of strong galvanized iron that have been in use for nearly a year, for growing Palms, such as *Latania borbonica*, *Dates*, *Coccoloba*, &c., and have found them to answer admirably. I have no doubt that they are superior to porous or clay pots for specimen plants of any description, and they are not so likely to be broken by accident. They can be manufactured, when the size is 1 foot in diameter, for say a third more cost than clay pots; I have not tried any smaller sizes. Were these pots to come into general use, they could doubtless be cheaply manufactured. Tin-plate would be strong enough for pots of small sizes, and would last some time before rusting.

**Narcissi in Pots.**—A writer in a contemporary, who is inclined to be severely hypercritical, speaks of *Polyanthus Narcissi* as ungainly plants when grown in pots, and intimates that the general public have done with them, as far as their cultivation in pots is concerned. I cannot believe that the general public have done with them; they belong to a section of fragrant, free-blooming bulbs, which lovers of flowers will not willingly let die, and they are very easily managed. Such varieties as *Bazelman major*, *Gloriosa*, *Grand Primo*, *Grand Menarque*, *Lord Canning*, and *Soleil d'Or*, are far too good and too acceptable as scented conservatory plants to be neglected. While, however, I stand by the *Polyanthus Narcissus*, I desire also to commend some of the border varieties as peculiarly well suited for pot culture. I have this season grown but two of these in pots, but they will never in future be wanting in our group of spring-flowering plants. One is *Narcissus Trumpet major*, the other *N. Trumpet sulphur*. These are the names under which they are obtained from the bulb growers in Holland. They are both single Daffodils; the former has bold yellow flowers, the latter is not quite so large. They can be obtained from any bulb dealer under the names I have given, and they are objects of great beauty when grown in pots. I use a good rich soil, such as I would for Hyacinths, and put four bulbs in a 32 or 24-sized pot.—*Quo.*

**Imantophyllum miniatum.**—This fine plant is generally considered to belong to stove plants, I believe, though it is sometimes grown in the greenhouse, and I have even heard of it being put out in the flower-beds in summer and doing well. It, however, clearly delights in a stove temperature, and comes into flower early in spring. Under such circumstances it throws its fine large trusses of orange-coloured flowers well up above the dark-green foliage, and is then a grand object for a vase. After it has done flowering is a good time to give the plants a shift when they are grown for early spring work; but when grown in a greenhouse, early spring would be the best time for the operation. The plant divides easily, and delights in a good strong sandy loam mixed liberally with leaf-mould. It should be well exposed to light during the season and watered liberally, and now and then with weak liquid manure. Treated in this way, robust thick-necked plants will be the result, and magnificent trusses of bloom supported on sturdy stems. In winter water must be given sparingly, but anything like "drying off" must be avoided.—*J. S. W.*

**Joining Hot-water Pipes.**—I am about to fix some hot-water pipes. Can any of your readers tell me which is the best method of making the joints? Should I use india-rubber collars, or white and red-lead? The former method has been recommended to me; but it is so far a novelty in Somersetshire that our workmen do not feel confident that the result will be satisfactory.—*W.*

### ST. JOHN'S NURSERY, WORCESTER.

It is our intention to give a series of illustrated accounts of our great commercial gardens, some of which are of far greater importance as regards instruction than the best supported public ones; and of the many great nurseries in the United Kingdom none is more remarkable or interesting than the well-known St. John's Nursery, belonging to Mr. Richard Smith, at Worcester. The rich and charming collection of beautiful plants from all temperate parts of the globe which it contains has a world-wide celebrity, such kinds only being cultivated as are likely to prove superior to, or more interesting than, their predecessors. These selections are increased and grown here in such vast numbers that one is puzzled to imagine what becomes of them. Of the grand old evergreen *Magnolia grandiflora* one finds here some twenty varieties, quite one hundred sorts of Tea-scented Roses, all well deserving of a place under glass, and one of the finest collections of wall shrubs extant. To give, indeed, some idea of the way in which some genera are represented here, it may be well to give the numbers of kinds of some important families of trees and shrubs, which are as follows:—

Abies . . . . . 41	Junipers . . . . . 53	Magnolias . . . . . 34
Cupressus . . . . . 31	Pines . . . . . 72	Oaks . . . . . 75
Piceas . . . . . 21	Taxus . . . . . 30	Spiræas . . . . . 28
Retinosporas . . . . . 23	Cydonia . . . . . 23	Weigelas . . . . . 32
Aucubas . . . . . 21	Cytisus . . . . . 19	Ivy . . . . . 32
Clematis . . . . . 53	Elms . . . . . 27	Lilac . . . . . 35
Daphnes . . . . . 17	Heaths . . . . . 29	Maples . . . . . 22
Hollies . . . . . 76	Hydrangea . . . . . 20	Privet . . . . . 15
Biota . . . . . 19	Laurel . . . . . 14	Thorus . . . . . 33

These figures indicate a preference for the noble order Conifera, of which Mr. Smith possesses one of the finest collections anywhere to be seen. The department devoted to grafting and otherwise increasing rare Conifers here is most interesting, grafting being the only mode of multiplying some scarce kinds, of which it has been impossible to obtain seeds either on account of the difficulty of procuring them or because the kind may have happened to have been a natural sport differing widely from its parent, yet so unfixed in its variation that its seed (if procurable) would have returned to the normal type. Indeed, the difficulty of obtaining seeds of rare Conifers is more frequent than is generally imagined, and in these days of telegrams and high pressure speed as applied even to horticulture, it does not do to be behind the age; therefore, in order to overcome the difficulty, invention has been taxed to select for stocks the closest allied kinds of Conifers to those it is desired to graft upon them; and to an accurate observer it is surprising how soon a suitable stock is seized upon, potted, established, and then carefully grafted at the right season. Afterwards it is watched and tended daily for a few weeks in a close Wardian case, when a thriving young specimen of the desired kind, satisfactory in every respect, is the result. There is frequently another provoking trial to cultivators, which is this: A new and peculiar variety has to be multiplied, possessing, as usual, one leader only, and yet the plant must not be destroyed. In that case, recourse must be had to the side branches, say those of a Spruce Fir, which spread out flat, like the pinnae on a Fern leaf, rather than radiating from the upright stem like the spokes of a wheel. A cutting or graft of this kind, when put upright, will be flat instead of round, an anomaly which can only be rectified by means of patience and high cultivation. When the young plant is in luxuriant health, it must be cut down, when it will be almost sure to throw up one or more leading shoots or *fleches*, as the French term them; and these leaders, if grafted on suitable stocks, are no more to be objected to than Green-gages grafted on wildings, or Golden Pippins on Crabs. One never hears any one object to a Peach, Nectarine, or Apricot being budded on a Plum stock, and in that case the dissimilarity between graft and stock is vastly greater than that between Conifers and the stocks on which they are grafted.

Of late, increased attention has been paid to Ivy, and the so-called Tree Ivy, which has a bush-like form, is becoming a great favourite; it is, indeed, one of the most ornamental and beautiful of evergreens, its fine foliage and bushy habit being particularly pleasing during the winter months, when so many trees are uninteresting and leafless. There are twelve or more varieties of this kind of Ivy, some of which are

BIRD'S-EYE VIEW OF ST. JOHN'S NURSERY, WORCESTER.

variegated. It has been proved that cuttings taken from an Ivy which has assumed the tree form (as climbing Ivies do at an advanced age), and grafted on the common Irish Ivy, at once take the tree form without having to pass through the climbing state. To show how popular tree Ivies have become, we may mention that something like ten thousand plants of them are grafted in these nurseries every year. Perhaps no tree or shrub succeeds better in towns or smoky districts than Ivy, and for such places tree Ivies are invaluable, and, indeed, every arboretum or garden that does not already possess such plants should be enriched with a collection of them. In addition to these, Mr. Smith grows large numbers of climbing Ivies, including most of the varieties in cultivation, many of which are of a very striking character.

Here the eye and palate are great rivals, for one hardly knows which receive most favourable attention. Roses or fruits; undoubtedly the latter form quite a *spécialité*, for the many thousands of trees one sees in walking round are perfectly astonishing. One wonders where they all go to. Fancy 60,000 trees, all trained for walls or espaliers, ready for one season's sale! Why, at four yards apart, they would plant a length of eight miles and a half! Then there are besides immense numbers of standards, dwarfs, pyramids, and other forms of tree required for gardens, orchards, or houses.

The quality and symmetry of Mr. Smith's fruit trees must be well known throughout the country, for there is not a county in the United Kingdom into which there have not been introduced large supplies, and that they give universal satisfaction is proved by the largely increasing business. Perfection in cultivation is not easily attainable, but it is evidently striven after here. Half a million stakes are annually used in forming the trees, and no pains appear to be spared. Correctness of name is of primary consideration; for what is so annoying, after waiting for a fruit tree to bear, as to find that you have been deceived in the sort? The greatest care was given years ago to collect the sorts direct from their original sources where possible, and, in default of that, from the most reliable authority; and when doubt arose, proof was obtained by fruiting the kind in an orchard house. Stock plants of every particular variety are kept, and the most scrupulous attention is paid to the naming of the various sorts. During the time of budding and grafting, the greatest possible care is used to avoid confusion, and as from twenty-five to thirty men are employed at this work, it is not to be wondered at if an occasional error does occur; but in order to meet such an occurrence, the fruit foreman carefully examines every row when the trees are coming into leaf, when in full leaf, and again at the fall of the leaf, so that his practised eye inevitably detects an error should one have occurred, and the tree is at once destroyed.

Before walking round, Mr. Smith begged us carefully to try if we could find one blighted tree or one that appeared untrue, judging by others in the same row; it is only fair to say we did not observe one incorrect or diseased in all the stock. Of course aphides will occasionally attack almost every kind of plant, but they do not by choice feed on healthy trees; they no sooner make their appearance here than the trees are well washed with soft soap and water (the most effectual and speedy remedy) until there is no sign of a living insect; during the blight season some trustworthy men are always on the look-out for these pests, so that they have no possible chance of continuing their ravages for any length of time.

To give an idea of the importance attached to Roses, it is worthy of remark that 60,000 are yearly grown in pots under glass; 500,000 Rose cuttings for stock were put in last autumn, and there is a square of five acres and a half planted out entirely with Rose stocks for next summer's budding. Ten acres in the open air are devoted to Roses.

The collection of Oaks gathered together here is one of the most beautiful ever made, and besides the flowering and ornamental-foliaged shrubs, in which this nursery is very rich, there are forest trees, hedge plants, creepers, herbaceous plants, &c., all cultivated with the greatest care, frequently transplanted to render them safe for removal, and each plant from its earliest growth formed to make a handsome specimen. Thus, by early and constant care,

the most perfect shape that can be desired is obtained without stiffness or formality. For years past the object has been to collect and multiply all the good varieties that could be obtained, and he must be difficult to please who cannot be satisfied in such a choice collection.

We were particularly struck by the cleanliness of the nursery—there was almost a total absence of weeds. Much attention is paid to this, so that every plant may be free and healthy in growth, for, where weeds prevail, stock must suffer more or less.

For the rearing and cultivation of stock there are two acres and a half of glass, composed of 1,750 pit-lights, and twenty-four houses, from whence several millions of plants are produced annually, requiring 150 tons of garden pots and 100,000 wooden labels every year. The nurseries occupy upwards of 150 acres of fully-cropped ground. The principal drive, going straight through the nursery, is one mile long. This is crossed by another seven-eighths of a mile long. There are thirty-two miles of walks, though no more than are necessary to attend properly to the stock. 250,000 Rhododendrons, Conifers, and other evergreens, flowering shrubs, Clematis, &c., are annually grafted under glass.

The packing is carried on in four large sheds, the largest 145 feet long by 19 feet wide, to which a crane is attached for lifting heavy packages into the railway waggons, which call daily. To give an idea of the extent of this department, it is sufficient to mention that, from the commencement of October to the end of the year, from eighty to one hundred men are constantly engaged in executing orders, and the following material is required for one season's supply:—100 tons of straw for packing, 350 bundles of willow bands (each 3 feet round), 5,000 bast mats, 1½ ton string, £200 worth of baskets, £100 worth of crates, and 80,000 parchment labels.

Of the Weeping Beech—to the picturesque appearance exhibited by which we have on several occasions alluded—Mr. Smith has a beautiful specimen, which we have thought worthy of separate illustration (see p. 299). This fine tree is upwards of 25 feet in height, and has a stem some 6 feet in circumference at the base. The spread of its branches varies from 35 to 40 feet in diameter. It was struck by lightning during the summer of 1857, but instead of being riven to pieces, like the generality of lightning-struck trees, the electric fluid only seared some of the main branches, and the health of the tree has in no way suffered from the shock. As will be seen, it is a grand example of this variety of Beech.

**Rain and Vegetation.**—*The Bulletin* of the Torrey Botanical Club contains a suggestive paragraph in reference to the influence of trees upon rain and atmospheric moisture, as shown by the experience of the island of Santa Cruz in the West Indies. This island is said to have been a garden of freshness, beauty, and fertility twenty years ago; it was covered with woods, trees were everywhere abundant, and rains were profuse and frequent. The recent visit of a gentleman who had known the island in its palmier days, revealed a lamentable change, one-fourth of the island having become an utter desert. The forests and trees had been cut away, rainfalls had ceased, and the process of desiccation, beginning at one end of the island, had advanced gradually and irresistibly upon the land, until for seven miles it had become dry and barren as the sea shore. Houses and plantations had been abandoned, and the advance of desolation was watched by the people, wholly unable to prevent it, but knowing, almost to a certainty, the time when their own habitations, their gardens and fresh fields would be a part of the waste. Indeed, the whole island seems doomed to become a desert. This sad result is owing entirely, according to the belief of the inhabitants, to the destruction of the trees upon the island some years ago.

**Dimensions of the London Parks.**—The Ordnance Survey Department gives the following: St. James's, 58.5 acres; Green Park, 60.3 acres; Hyde Park, 386 acres; Kensington Gardens, 245.5 acres; the Regent's Park, 406.2 acres; Victoria, 223.8 acres; Southwark, 63 acres; Kennington, 19.7 acres; Battersea, 199.4 acres; Greenwich, 190.4 acres; These ten parks, together containing 1,852.8 acres, are all within the registration division designated "London," which comprises 78,080 acres. Beyond these limits, but still within the district served by the Metropolitan Police, there is also Richmond Park, with 2,015.5 acres; Kew Gardens, &c., with 322.8 acres; Old Deer Park, with 357.2 acres; Bushey Park, 993.9 acres; and Hampton Court Park, 576.7 acres. These last five parks contain together 4,266.1 acres, which, added to the area of the ten parks first above-named, make a total of 6,118.9 acres of public park in or about London.

THE FRUIT GARDEN.

AMERICAN GOOSEBERRIES.

MR. HOOKER, of Rochester, says: I was struck by finding, on the coast of Maine, an abundance of wild Gooseberries with

Smith's Improved Gooseberry.

fruit nearly as large and good as that of the Houghton. These were growing among rocks, and in poor soil. Expe-

New American Gooseberry "Downing."

rience with other fruits shows that we must look to native-grown seedlings for our best and most profitable sorts. Little

can be done to change or modify the constitution of a plant by special care or culture; we must go to the seed for all reliable variations, and when any disposition to vary from the original wild type is discovered, we must follow it up, and, in the end, secure the results most desired. With us the Gooseberry has not produced many new or promising variations; it has held well to the habit of all wild fruits. The only improved American Gooseberries which have come under my observation are the Houghton, a kind which strongly resembles the wild type, but which is more productive and somewhat larger, and better flavoured than those found growing wild. The Mountain.—This is very different from the first, and offers peculiarities of merit quite distinct and interesting. The plant grows tall and very large, and is abundantly productive of fruit. Both this and the Houghton are red in colour. Smith's Improved.—This variety presents the habit, slender branches, and moderately rapid growth of the Houghton, with much larger fruit, which is of a pale yellow or greenish yellow colour, and of excellent flavour. I am inclined to think that pruning and liberal culture will suit this variety well, and with these I do not see how it can fail to please. The accompanying illustration was taken from a well-grown plant in full fruit. The Downing.—This sort has stout heavy wood, very thorny, and an abundant rich foliage. I cannot say that I have found its fruit to be any great improvement in flavour on that of the Houghton, but it is twice as large as that variety, and it will, I think, be found that its increased size, remarkable vigour and productiveness, good colour, and certain crop, will place it among real acquisitions in its particular class. I look upon these new sorts as additions of real merit in themselves, and a strong assurance that, from their progeny we may reasonably expect soon to see a list of Gooseberries possessing all the good qualities that could possibly be desired in fruits of that kind.—*Cultivator.*

KEEPING LATE GRAPES UPON THE VINES.

My experience in reference to this matter is in exact accordance with that of your correspondent "J. S. W." (see p. 266), and I most willingly endorse his assertion that the best way to keep late Grapes is to allow them to remain upon the Vines. Like your correspondent, I have never yet been able to perceive that doing so had the slightest effect in exhausting or in any way impairing the health of the Vines. I have not unfrequently been in the habit of commencing to cut late Grapes at one end of the house, and have cleared all the fruit from the first Vine before cutting a single bunch from the second, and so on to the end; so that the Vines which occupied the end of the house were relieved of their fruit probably two or more months before a similar relief was extended to those which occupied the corresponding or opposite end of the structure. All were, however, generally pruned at the same time, viz., those from which the fruit had quite recently been cut, and the others from which it had been removed at an earlier period. Nevertheless all the Vines have usually started or broken simultaneously, nor have I ever been able to perceive, as I have just said, any diminution of vigour on the part of those which had been compelled to bear the burden of their fruit the longest. Up to this point I, therefore, coincide with your correspondent; but he then goes on to say—"Grapes hanging upon the rod after they are ripe are no more burden than the leafless branches themselves." "Growth and maturation are completed, and there is no demand upon the Vine." Now I must say that I entertain some doubts as to the correctness of this assertion; at all events I think the subject demands, and is worthy of, careful inquiry. Supposing we sever a spur or shoot bearing a bunch of ripe Grapes from the Vine; cover, say, the incision with sealing wax or some similar substance, but allow the branch and the bunch of fruit attached thereto to retain their original position, it will probably be found that in the course of a few days the footstalks of the berries will have become more or less flaccid, and that the berries themselves will ere long become less plump and firm than those whose connection with the Vine has not been severed; and if this be so, it will certainly go far to prove the existence of something like reciprocity between the ripe fruit and the Vine on which it is supported, and that the fruit, though ripe, continues to derive something from the Vine to enable it to retain its plumpness, &c. From what I have already said it will, however, be evident that I am by no means inclined to think that the extraction of this "something," whatever it may be, on the part of the fruit, tends in any perceptible degree to diminish the vigour of the Vine. It appears to me that if the advocates of the bottling system

were of opinion that ripe Grapes extracted nothing whatever from the Vines on which they hung they would hardly consider it necessary to put water in the bottles from which they suspended the bunches. The water contained in the bottles is doubtless expected to furnish the ripe fruit with a substitute for what the Vines would have supplied, had it been allowed to remain upon them. An idea of this sort induced me at first to think rather unfavorably of the bottling system, fearing, as I did, that if any portion of water was taken up by the fruit, that it would necessarily deteriorate its quality, and I confess myself, as yet, not altogether disabused of this notion; although it may be possible that what is supplied to the ripe fruit by the water in the bottles may not greatly differ from what would be supplied to it by the Vines themselves, if it was allowed to remain upon them. A year or two ago, while engaged in suspending from bottleless bunches of ripe Grapes, chiefly the Lady Downe's variety, I, by way of experiment, omitted putting water into some dozen or more bottles, and the result was pretty much as I had anticipated; in the course of a fortnight or three weeks I found that where the water was absent the footstalks of the Grapes had nearly all dried up, which was not the case in most instances where the end of the spur or shoot bearing the bunch was inserted in the water. Wherever a late vinery can be kept tolerably dry, and the introduction of plants in pots, &c., requiring water can be avoided, there can hardly be a doubt about the Grapes keeping best upon the Vines. But if, from whatever circumstances, these necessary conditions cannot be secured, then it may be advisable to have recourse to a dry, well-ventilated room and bottles of water, and if early in March, when the sap may be expected to be upon the move, any good fruit should still remain upon the Vines, I think it is then advisable to cut off the spurs bearing bunches, and to insert the ends of the former in bottles of rain-water, which may be regarded as a sort of *dernier ressort*, which sometimes succeeds admirably, but not always.

*Culford, Bury St. Edmunds.*

P. G.

**Living Copings.**—There is one kind of protection that has not received the attention it deserves, that is, living copings of Ivy, Roses, Virginian Creepers, Jasmines, Clematises, &c. At first sight it might seem that few of these plants, unless it were the Ivy, had sufficient density of foliage to afford much protection to the trees below, but it is quite otherwise. I have observed a crop of Peaches saved year after year by the protecting power of a few sprays of a Virginian Creeper. It is a simple matter to run a few wires on studs projecting a foot or so from the wall immediately under the coping, and to clothe these wires with climbing plants, thus crowning the wall with verdure and beauty, and saving our fruit crops by one and the same process. Fancy a coping of *Maréchal Niel*—one of the best Roses possible for this purpose, owing to its free growth and early leafage and flowering—surmounting a wall studded with noble Peaches underneath. Living protectors have at least this merit, above all others; they would be cheap at first cost, durable, tolerably efficient, and assuredly beautiful.—*D. T. F.*

## THE GARDEN IN THE HOUSE.

### CHAMLEDOREAS AS HOUSE PLANTS.

If any one genus of Palms pleases me more than another it is this pinnate-leaved one. There are, however, many others in the pinnate section of great beauty, of which I may instance the genera *Attalea*, *Cocos*, *Calamus*, *Plectocomia*, &c., but I have found that whilst they are superb ornaments of plant houses, those kinds which develop their beauties in a sufficiently small state to be introduced to the dwelling-house, have not a robust constitution to enable them to remain pleasing to the eye for any length of time, whilst in the case of *Attalea* and some other genera, the plants become too large for ordinary apartments, before they assume their true character; indeed, with such kinds, a majestic port is their chief attraction, which, as a matter of course, cannot be developed indoors or upon the dinner table. *Chamedoreas* like plenty of water if the drainage is, as it should be, good; that is, it is best to err a little on the side of a too bountiful supply of water, than to allow them to suffer from drought in the least degree; on the other hand it is neither good policy nor good culture to keep the saucers always full of water. There is a great number of species of *Chamedorea* now in cultivation, some of which are closely allied to each other, and as the object of indoor

gardeners should be to produce as much variety as possible, it would be useless to recommend such as require a practised eye to distinguish one from the other. If, therefore, the following list of species be considered a small one, it will, at least, have the merit of distinctiveness.

**C. GRAMINIFOLIA.**—It would almost be impossible to name a more elegant object than this fine Palm; indeed, but for one (I allude to *Cocos Weddelliana*), I should not have the least hesitation in asserting it to be the most graceful Palm in cultivation; its stem is as slender as that of a Reed, the pinnate leaves reach a length of 3 feet, and have a most beautiful curved outline, and the pendulous dark green pinnae are some 10 inches long; each leaf, indeed, presents the appearance of a large graceful feather, and no more beautiful object can be found for the embellishment of the drawing-room or dinner-table. In winter, however, I would not risk it in the dwelling-house; but whilst small, it will thrive well enough in a Wardian case. It is a native of Costa Rica.

**C. ERNESTI-AUGUSTI.**—In this species, which is a native of New Granada, we have a grand contrast to the preceding; for the leaves, which are pale green, are from 1 to 2 feet long, by about 10 inches broad, situated upon short foot-stalks, and except that they are deeply cleft at the top, they are entire and slightly plaited; they are supported upon a straight annulated stem, which bears large branching spikes of flowers when quite young; these, as the seeds approach maturity, change to a deep rich red, rendering this Palm both conspicuous and ornamental. It thrives admirably under cool treatment.

**C. WENDLANDII.**—This species I consider to be the best of the genus for room decoration; it has broad dark green arching pinnae of great beauty. Plants of it stood in the open air, fully exposed to the sun, through the months of May and June, during the past season, without any care, the only ill effects arising from which was loss of colour; this, however, was soon restored with a little soot-water, and they are now of a rich dark green, and remarkably healthy. It is a native of Mexico.

**C. SARTORII.**—This is another beautiful kind, which bears a large crown of beautiful leaves, and bright-red flower spikes. It is a gem for house decoration. It comes from Mexico.

**C. ELEGANS.**—This, as its name implies, is a charming plant. It is of somewhat robust habit for a *Chamedorea*, the pinnate leaves reaching a length of 3 or 4 feet, the pinnae being from 6 to 9 inches long by 1 inch in breadth, and brilliant green; these, however, are the dimensions of mature plants; when smaller, it is a superb Palm for any purposes where plants are admissible. It is a native of Mexico.

**C. ARENBERGIANA.**—This acquires about the same dimensions as the preceding, but differs from it in having the pinnae lengthened out into long tails, which renders it very attractive.

**C. MARTIANA.**—This is a slender dwarf species, which produces many little stems, bearing narrowly pinnate, drooping deep green leaves, and is a charming object in a Wardian case. It is a native of Chiapas.—*Furmer*.

**A Garden Land.**—The climate of Tasmania is by far pleasanter than that of any part of the mainland. There are, one may almost say, no mosquitoes. Other pernicious animals certainly do abound—but then they abound also in England. Everything in Tasmania is more English than in England herself. She is full of English fruits, which grow certainly more plentifully and, as regards some, with greater excellence than they do in England. Tasmanian Cherries beat those of Kent—or, as I believe, of all the world—and have become so common that it is often not worth the owner's while to pull them. Strawberries, Raspberries, Gooseberries, Plums, and Apples are in almost equal abundance. I used in early days to think a Greengage the best fruit in the world; but lately at home, Greengages have lost their flavour for me. I attributed this to age and altered palate; but in Tasmania I found the Greengages as sweet as they used to be thirty years ago. And then the Mulberries! There was a lady in Hobart Town who sent us Mulberries every day, such as I had never eaten before, and as, I feel sure, I shall never eat again. Tasmania ought to make jam for all the world, and would do so for all the Australian world were she not prevented by certain tariffs.—*A. Trollope*.

## THE LIBRARY.

### A GENERAL SYSTEM OF BOTANY.\*

Of this excellent book, as it now stands, we cannot speak too highly. It is absolutely without parallel, comprising, as it does, in its two parts, the fullest and best illustrated treatise on the organization and anatomy of plants, and the most complete and satisfactory arrangement of the families. It is, indeed, in some respects an improvement upon the original work, which has hitherto stood unrivalled in its excellence as a "clear and precise structural and morphological account of the Botanical Orders, with a sketch of the affinities of each,

Compositæ, the most highly-organised family, and ends with the families of lowest organisation. This alteration enhances the value of the work in no small degree to the English student. The additions consist of twenty-seven new Orders (twenty-four are mentioned in the preface, but Humiriaceæ, Philydree, and Xyrideæ have been omitted in the enumeration there) of plants which are mostly tropical, and twenty-three of which orders appear to have been totally unknown to the authors of the original work, as no allusion to the genera is to be found in it. Of the remaining four they have classed Triurideæ under Burmanniaceæ, Burseraceæ under Terebinthaceæ, and Samydaceæ under Bixineæ; while all the genera of Ficoideæ (except *Trianthema*, *Gisekia*, and *Limeum*) are differently arranged.

Flower-spike of *Gunnera scabra*.

*Cephalotus follicularis*.

its geographical distribution, and principal uses in medicine and the arts." In the English edition, the editor has, for obvious reasons of convenience, adopted the arrangement of De Candolle, which has been for some time established in our schools and universities, and with which our working botanists and herbarium-keepers are familiar. In the original, the sequence is that of A. de Jussieu, which commences with the

\* "A General System of Botany, Descriptive and Analytical, in two Parts. Part I. Organography, Anatomy, and Physiology of Plants. Part II. Iconography, or the Description and History of Natural Families. Translated from the French of E. Le Maout, M.D., and J. Decaisne, Member of the Institute, by Mrs. Hooker. Edited and Arranged according to the Botanical System adopted in the Universities and Schools of Great Britain by J. D. Hooker, M.D., &c., Director of the Royal Botanic Gardens, Kew. In one Volume, medium 8vo, with 5,500 Woodcuts, from Designs by L. Steinheil and A. Riocreux." London: Longmans, Green, & Co. 1873.

There is also much additional matter in the shape of valuable notes appended to most of the orders, the whole concluding with a classification of plants by the natural method, and an Analytical Synopsis of the classes, sub-classes, cohorts, and orders, the want of which was a serious deficiency in the original. The translation has been carefully done, and, although not literal in many parts, faithfully renders the sense of the original. The English edition is also much more convenient in size than the French, and the paper, printing, and *tout ensemble* of the volume are all that can be desired. We give an extract, to show how the orders are treated, and also specimens of the illustrations.

#### SARRACENIACEÆ (ENDLICHER).

Perennial herbs, inhabiting the turfy, spongy bogs of North

America and Guiana. Root fibrous; leaves all radical, with a tubular or amphora-shaped petiole; blade small, rounded, usually lying on the orifice of the petiole. Scapes naked, or furnished with a few bracts, 1-flowered (Sarracenia, Darlingtonia), or terminated by a few-flowered raceme (Heliamphora); flowers large, nodding; sepals 1-5, free, very much imbricated at the base, sub-petaloid, persistent; petals 5, free, hypogynous, imbricate, deciduous, rarely 0 (Heliamphora); stamens  $\sigma$ , hypogynous, free; filaments filiform; anthers 2-celled, versatile, opening by two longitudinal slits. Ovary free, 3-5 celled, placentas prominent at the inner angle of the cells; style terminal, short, sometimes dilated at the top, as a 5-angled or lobed petaloid parasol, with five radiating nerves (Sarracenia), or 5-fid, lobes narrow, spreading, reflexed, stigmatiferous (Darlingtonia), or obtuse, and terminated by an obscurely 3-lobed stigma (Heliamphora); ovules numerous, many-seriate, sub-horizontal, anatropous, raphe lateral; capsule 3-5 celled, loculicidally 3-5 valved; seeds  $\sigma$ , small; testa crustaceous, sometimes loosely reticulate (Darlingtonia), or membranous and winged (Heliamphora); albumen copious, fleshy; embryo minute, near the hilum.

GENERA.

Sarracenia. Darlingtonia. Heliamphora.

This little family approaches Papaveraceae in hypopetalism, polyandry, numerous ovules, capsular fruit, fleshy copious albumen, and minute basilar embryo; but Papaveraceae differ much in habit, proper juice, caducous dimerous calyx, and one-celled ovary, with parietal placentation. Sarraceniaceae are connected with Nymphaeaceae by the same characters, and also by the always radical leaves, one-flowered scape, and aquatic habitat; but Nymphaeaceae differ in their numerous several-seriate petals, placentation, sessile stigma, and double albumen. Certain affinities or analogies have also been indicated, which link Sarraceniaceae with Droseraceae, Pyrolaceae, Nepentheae, and Cephaloteae.

[All are natives of America, and chiefly of the United States. Darlingtonia inhabits the Rocky Mountains, and Heliamphora the Roraima Mountains of Venezuela. Of the properties of Sarraceniaceae little is known. Sarracenia rubra has been vaunted in Canada as a specific against small-pox, but has not proved such. The pitcher-shaped leaves are effective insect traps; a sugary secretion exudes at the mouth of the pitcher, and attracts the insects, which descend lower in the tube, where they meet with a belt of reflexed hairs, which facilitate their descent into a watery fluid that fills the bottom of the cavity, and at the same time prevent their egress.—*Ed.*]

COOKING BEET.

IN the process of cooking, Beet is frequently made very hard and almost inedible, and the seedsman or gardener is made to bear the consequences of the cook's shortcomings. Following up our experimental trials, we have looked into the cook's department, and offer to our readers the following conclusions:—1. In preparing Beet for cooking, the greatest care must be taken not to bruise the skin, or in any way wound the root; and if by accident any injury has been done to the root, bake and not boil. 2. If a deep crimson hue is the colour preferred in the Beet, or a firm flesh, this is best attained by baking the roots. 3. If a light clear bright colour is desired, or a soft juicy flesh, then boiling will secure this. 4. If a rich agreeable flavour is sought for, then select the Beet which, before cooking, has the most purple in it, and the flavour may be discovered by masticating a small portion of the uncooked root. If good it will leave a rich agreeable flavour on the palate without any sensation of astringency in the throat. Barr's selection of Nutting's Beet has the desired qualities in the highest degree. 5. Crimson-fleshed Beets are all very rich in flavour, but when masticated uncooked, an astringency will be discovered as above described; this class of Beets, however, has its advantages, inasmuch as it can be sown earlier. Barr's selection of Pine Apple Beet is the most desirable of these; it may be sown very early, and will not run to seed. 6. Scarlet-fleshed Beet possesses least of the saccharine flavour, and Nonpareil best represents this class.—*Barr and Snyden's Catalogue.*

**Mould on Preserved Fruits.**—A lady of considerable scientific attainments said, at the last British Association meeting, that the atmospheric germ theory of vegetation has a practical bearing in household economy. The old practice in making jams and other conserves was to leave the pots open for several days before sealing them. She says that this gives the germs in the air an opportunity to settle in the rich soil of preserved fruit; and the seeds thus sown produce an abundant crop of the microscopic vegetation known as mould. It is far better to seal jars while their contents are still hot.

GARDEN DESTROYERS.

MICE.

I HAVE not the slightest doubt that the short-tailed field mouse or vole is the culprit in cases in which Ash trees are barked. The long-tailed field mouse does not make tunnels and runs in Grass and pastures, but the short-tailed vole does. The former is very destructive to the bulbs of yellow Crocus (it seldom touches those of any other colour), and also to all kinds of Peas. The vole prefers green meat. I put a small tree of *Pyrus spectabilis* a month or two since in by the heels for a time, in a heap of leaf-mould, and some of the branches were soon barked; shortly afterwards my dog turned out two short-tailed voles in the exact spot where the tree had been. They had just eaten off every umbel of bloom from a magnificent patch of *Iberis gibraltarica* on my rockwork. The fragments were strewn all round their hole. I immediately poured a large supply of boiling water therein, and trust I have "settled" the inmates. Can any one tell me how to bait a trap for these mice? They have hitherto beaten me altogether. They are very destructive to the young leaves of Carnations in the spring. The long-tailed field mice are easily disposed of by means of traps baited with toasted cheese. I caught seventy this winter in my garden in eight weeks. H. HARPUR CREWE.

*Drayton-Beachamp Rectory, Tring.*

VINE PESTS.

AT page 262, a correspondent writing on this subject recommends a mixture of lime and sulphur as a remedy for red spider, or rather a solution of the mixture applied with the syringe to the foliage of the Vine, for the destruction of that pest. Lime and sulphur boiled together will make a liquid that will destroy any foliage, and if weak enough to be used with safety, I should doubt very much if it would kill red spider. It may be well to caution your readers as to the danger that may arise from the use of such a mixture. The same writer recommends coating the hot-water pipes with sulphur for the same purpose, without any caution as to the time when such work should be done. Now if the house be full of young Grapes they may be all rusted and spoilt, but I am quite sure the red spider will not be killed. Still more dangerous is his advice to strew sulphur on fresh-slaked lime, an operation which would be little less destructive than burning sulphur in the house. I have no doubt that it would kill the red spider and also the foliage on which it feeds; indeed, I have heard of serious mischief arising in two cases from this way of trying to kill this pest. My own experience of sulphur is that it is the only known remedy for mildew, but that it is quite useless as a destroyer of red spider when feeding on growing plants. Then again, the same writer recommends hot coals in fumigating with tobacco. As these often give off sulphur, tender foliage is thus frequently destroyed, and I have known instances in which tobacco paper of good quality has been blighted for injury caused in that way. Not long since I was sent for by a gentleman to see his Vines, which were dying. He had read in a gardening paper, he said, that it was a good thing to dress Vines with linseed oil to destroy insects and their eggs, and he had followed the advice. The consequence was his Vines had to be cut down to the ground, for they were unable to start their buds the following spring.

*Chilwell.*

J. R. PEARSON.

**Crocus Enemies.**—Long-tailed field mice do not, I believe, do any appreciable damage to Crocus flowers. The culprits in this case are sparrows. A neighbour of mine who grows large quantities of *Crocus biflorus*—the Scotch Crocus—sometimes has almost every bloom pecked to pieces by these birds. I believe they find the nectary appetising food. Slugs eat pieces out of the petals, and sometimes gnaw off a whole petal, but they do not destroy the flowers piecemeal like the sparrows. I believe that chaffinches sometimes lend a helping hand. I have seen them picking off the flowers of Primroses and Polyanthes.—H. HARPUR CREWE, *Drayton-Beachamp Rectory, Tring.*

**Bullfinches v. Gooseberries Bushes.**—The man who has pruned our Gooseberry trees here for these 35 years declares that never until this year have bullfinches attacked the buds. This season one-half of them is pecked out by these little depredators. I know personally that for five successive seasons they have not molested them. These mischievous little pests are, however, protected by the late Act of Parliament.—R. GILBERT.

**May Bugs.**—In the Royal forests of Bischofsroda a successful experiment has lately been made in destroying may bugs on a large scale. The modus operandi was suggested by the observation that these bugs always select warm and loose ground for the deposition of their eggs. Consequently, 17 artificial breeding places were prepared by covering fresh cow-dung with fine earth; and by the middle of July these were found full of eggs or grubs. After carefully collecting these eggs, &c., they were burnt outside the forest.

## TEMPERATURE INDICATOR.

WHERE the forcing houses about a place are numerous, and where different temperatures have to be kept up in almost every house, it is quite necessary that the young men in charge of them should have some index or guide as to the proper temperature to be kept up in each. The following diagrams

exhibit an invention of Mr. Titus Salt, of Milner Field, which supplies the desideratum in question in a very efficient way. The contrivance simply consists of two discs made to revolve and to display two figures at the opening in the case, so that the head gardener can fix at any point, from 1 to 99, whatever

temperature he may wish to be kept up in the house. The whole is made (or ought to be) of copper, and the discs ought to project a little below the case, so as to be moved easily by the finger. The discs are stamped with the numbers and afterwards painted. These little indicators may be seen in use in many of the houses at Milner Field.

### WORK FOR THE WEEK. PRIVATE GARDENS.

**Flower Garden.**—This department is now becoming every day more interesting. Hyacinths are at their best, and Tulips are beginning to expand; therefore loosen the soil a little amongst them, so as to give the beds a neat appearance. Keep beds containing Iberises, Daisies, Alyssums, Pansies, &c., also in good order. Such beds as are empty should be planted with *Viola cornuta*, bedding Pansies, Nasturtiums, Tropæolums, Hollyhocks, roots of *Fuchsia fulgens*, *Salvias*, Cannas, Dahlias, *Echeverias*, the finer kinds of herbaceous and other plants, all of which should be put into the positions they are destined to occupy throughout the rest of the year. In the event of frost, a slight protection in the way of evergreen branches or Broom twigs may be placed amongst them. Various kinds of annuals may now be sown out of doors; even such kinds as Stocks, Asters, and other rather tender sorts, may be safely sown on a warm border, and afterwards transplanted. Thus treated, although later in coming into bloom, they continue long in flower. Have all pruning of Roses and evergreen trees and shrubs finished for a season, and likewise the tying and training of wall and pillar plants. Plant out bulbs of *Tigridias* in flower beds, marking with little pegs the places in which they are put, so that in refilling the beds next month they may not be disturbed. Sow biennials for next year's blooming in a border, so that they may be afterwards transplanted in moderately rich soil. Bedding plants of all sorts must now be as freely exposed to air as is consistent with health; but weak and very young ones must still receive more favourable treatment, in order to encourage growth.

**Conservatories.**—Plants in conservatories have now started vigorously into growth, and should therefore be judiciously thinned,

especially in the case of rampant growing sorts; rub away all weak and superfluous growths, and do not permit the remaining branches to become too thick, strong well-ripened wood being what should be aimed at. Keep up successions of plants in the forcing-house, greenhouse, stove, or pits, to take the place of such as get out of bloom in the conservatory. Azaleas done flowering should be repotted in a compost of good fibrous peat, intermixed with some loam, leaf-mould, and sand, and should be removed to some warm structure to complete their growth. Whilst there they should be syringed twice a day, and their shoots should be pinched at the third or fourth leaf of the first growth, but afterwards they should be encouraged to grow. Old plants seldom require repotting, but should be fed with manure water. Good syringings will now be necessary; they encourage growth and wash the foliage. Fumigate on a calm dull evening, if insects are troublesome; but, if fumigation be objectionable in the conservatory, remove the infested plants to a pit or frame, and fumigate them there.

**Greenhouses.**—Shift Balsams as they require it, using rich material for the purpose, and give them, if possible, the benefit of a little bottom heat. Treat Cockscobs in a similar manner. Select some of the finest plants of *Humea elegans* for conservatory purposes. Give them a shift if they require it; if not, supply them freely with manure water. *Cyclamens* that have done blooming store away in a pit or frame, but do not keep them wholly dry. Those bearing seed place on a shelf in any of the houses, in a position near the light, but shaded from strong sunshine. Thin out plants of ornamental Grasses that were sown in pots, and keep them near the glass. Never permit Lilacs in pots to suffer from want of water, and keep them near the light, in order to induce strong flower-bearing branches. Train tree *Mignonette*, and keep up a supply of select varieties of the common kind in pots. Good drainage, moderately rich soil, plenty of water, and a little shade are necessary for the production of good *Mignonette* in pots. Annuals, such as *Clintonia pulchella*, *Brachycome*, *Schizanthus*, *Salpiglossis*, *Portulacas*, *Browallias*, &c., should be sown again to succeed those sown three weeks or a month ago. They should be thinned as they advance, or pricked off and potted separately. Sow some Globe Amaranths, and treat them precisely in the same way as Balsams, except that they do not require so much pot room; and too rich soil in this case is rather objectionable than otherwise, as it often causes them to damp off quite suddenly when in flower. Stake herbaceous *Calceolarias*, and now that their flower buds are developed, supply them occasionally with manure water; a cool dry house and a position close to the glass suit them best. Cut back early bloomed *Cinerarias*, and keep some of them in a frame with a north aspect for late flowering. Set outside such plants of *Tropeolum tricolorum* as have done flowering; but, if seed is required to be saved, the plants are better kept under a roof, a cool-house or shed being quite good enough for them. Train out and tie the shoots of pot Roses, admit air freely to them, and keep the plants near the light. Place a mulching of manure on the surface of the pots of *Statice*s, water freely, and keep the plants in a warm pit or corner of the greenhouse. Callas that were brought early into flower, and which are now throwing up suckers, may have the latter separated and potted singly; such plants of these as are now in flower, or are showing bloom, should be kept in a warm place and well watered, a little liquid manure occasionally being beneficial to them. Plants of *Lily of the Valley* that have done blooming should be stored under stages, or in frames, and kept moderately dry. Plants of show and fancy *Peargoniums* that are required for late flowering cannot be kept too cool, provided they are kept out of the reach of frost and cold draughts. For earlier blooming sorts warmer treatment is necessary; but, under any circumstances, a position for them near the glass is of primary importance. Zonal *Pelargoniums*, for the decoration of the conservatory, must be kept growing. *Chrysanthemums* may now be set out of doors at the base of a wall, or plunged in a border, and the old stools turned out of their pots and transplanted in borders.

**Greenhouse Hard-wooded Plants.**—Let *Camellias* done blooming be placed in warmer quarters, and old unshapely plants of them may be cut back and placed under similar circumstances, to induce new growth. Cut back *Epacris*s that have done flowering, and place them in a close frame until they begin to grow, when they should be repotted in a compost of fibrous peat and some sand. Cut back soft-wooded *Heaths*, and pot both hard and soft-wooded kinds, after they have begun to grow a little, in good fibrous peat and sand. Hard-wooded greenhouse plants, as a rule, if not already done, should be potted now and kept rather close until the roots have taken well to the new soil. Old plants do not require potting oftener than once in four or five years, and even then perhaps it may not be advisable to increase the root space; therefore the ball must be reduced, and the plants again potted in good compost in the same sized pots as those out of which they came.

## MARKET GARDENS.

**French Beans.**—This being an exceptionally late season, and the earth cold and wet, the first sowing of these, instead of being made early in April, has been advisedly delayed until now, when they are being put in in rows between lines of Lettuces planted 2 feet apart; if the drills for the reception of the seeds be opened in the first part of the day and the seeds sown in the afternoon, when the ground about them will be nice and warm, they will not be so likely to suffer. Draw the soil over the seed with the feet and leave the rows, as it were, in little ridges. On a warm well-sheltered border draw drills 15 or 18 inches apart and plant therein, 5 inches apart, French Beans that have been raised in heated frames; if the situation be very favourable they will survive without any artificial protection. The safest way, however, is to prepare a piece of well-sheltered ground, and to draw lines 3 feet apart across it, and others 2½ feet asunder along it, and upon every little square thus marked place an ordinary handlight, under which plant eight French Beans. If there are not sufficient handlights for the whole space to be planted, use half-bushel vegetable baskets; but as these are so open to wind they should be covered for a time with mats. The handlights being now removed from the Cauliflowers, are used for Beans, and after they become established the handlights will be available for Vegetable Marrows. Frames may also be used for the French Beans, when four rows should be planted under each light, the plants being about 4 inches apart in the row. After the plants have taken fresh root, plenty of air must be admitted. The frame produce is generally the earliest.

**Cucumbers.**—These must be planted as the plants are ready and convenience permits; the dung-pits yet to be made may not be quite the width of the frame, but formed so that the greatest heat may be immediately under the plants, which can be effected by confining the pit within 6 or 9 inches at back and front of the frame. Before planting, introduce the soil and leave it roughly undulated, so that it may become equally warmed before the roots of the plants are inserted amongst it. In raising Cucumbers after the seed has germinated, the young plants are pricked off two in a 6-inch pot, and in this way, without separation, they are planted, the contents of each pot being placed under each light. Succession plants are of little or no use, for, from several years' observation, it has been found that the earliest planted Cucumbers are the first to produce fruit, and that under proper treatment they continue in good bearing condition quite as long as any of the so-called succession plants; indeed, the Cucumbers from April to October should be the produce of one sowing, or two at the most. A few reserve ones should, however, be kept in stock in case of some mishap.

**Tomatoes.**—These should now be pricked off from the seed-pans into pots, say four into a 6-inch pot, and the pots plunged in a row along the back in the Cucumber frames. A frame may, if necessary, be specially prepared for them, when, instead of being pricked into pots, they may be pricked into the soil, and afterwards, when they become too thick there, dibbled into pots in a separate frame. In this latter way they are much more manageable than they otherwise would be.

**Celery.**—The seedlings sown on the beds that were covered with litter, like those for Turnips, are now up, having germinated freely; therefore remove the covering throughout the day, and if the beds be dry, water them through a fine rose. If long rods or spars of wood be laid across the beds about 6 or 8 inches higher than the soil, mats and litter can be more easily applied at night, and removed in the morning.

**Turnips.**—The first main sowing has made good progress, and a second should, if not already done, be sown broadcast. Those sown on the heated beds have passed safely into the rough leaf, and promise well.

**Radishes.**—From all sowings now remove the litter with which they have been covered, and what cannot be converted into manure build into a stack. Sow according to requirements and land to spare for that purpose. Those sown in frames have been marketable for some time past; those grown on heated beds and covered with litter are now in fine saleable condition, and with favourable weather the first outdoor sowing will soon be coming into use, especially those next the foot of walls, fences, or hedges.

**Lettuces.**—Those planted in frames during winter have all been planted, and are in most cases growing well. Some of them have been planted in fields in rows 18 inches apart, others 20 inches apart, with a line of Parsnips between them; some between rows of Coleworts, so that they are now fully occupying the space emptied by the removal of the latter; others in rows, 15 inches apart with a 2-foot space between every two, this space being reserved for Runner or French Beans; some in rows between the lines of Cauliflower, and alternately in the same line as the Cauliflower, and others between rows of spring Cabbages, with sets of Seakale planted between the

Cabbages and Lettuces. Keep the hoe constantly at work amongst them, and use it deeply, for the crop is much later this spring than last. Thin a little those sown in February in frames, and fully expose them during the day. A succession to succeed them should have been sown in a warm border.

**Cauliflowers, &c.**—The earliest Cauliflower is considerably behind what it was at this time last year; therefore encourage its growth by always maintaining a loose surface soil amongst the plants, and still preserve the handlights for them, unless you regard the French Beans as more deserving of such assistance. Cauliflowers planted amongst Cabbages have borne up well, and are looking moderately promising; those, too, appear to be in good condition that have been planted at the base of trenched ridges, which are now being almost levelled from repeated hoeings. Sometimes the ground before planting is sown broadcast with Radishes; then the Cauliflowers are planted in rows 2 or 2½ feet apart, and lines of Lettuces and alternate plants of the same are likewise planted amongst the Cauliflowers. Spinach is sometimes substituted for Radishes; but Lettuces, as a rule, are then dispensed with, as the Spinach, being of quick growth, is apt to overgrow and choke them. Clear off Colewort plantations, as the ground will be required for French Beans, Vegetable Marrows, Beet, &c. Thin out the Cabbage plantations, and bunch the thinnings as Coleworts, Cabbages (both green and red), sprouting and other Broccoli. Some Savoys, Brussels Sprouts, &c., should be sown in some miscellaneous border; indeed, if they had been sown a week or ten days ago they would have been more seasonable. Stakes must be prepared for the support of the Coleworts that are being saved for seeding purposes, as they are just coming into bloom.

**Rhubarb.**—Plantations formed this spring are growing away strongly, and from the intervening space between the lines a crop of Lettuces, French Beans, Cauliflower, Cabbage, Spinach, Brussels Sprouts, &c., may be taken, yet it is not advisable to crop the ground too severely. Keep gathering from the old plantations as they continue to yield, always pulling away the leaves and never cutting them, and in tying them into bundles keep the best of the leaves towards the outside and the smallest within.

**Miscellaneous.**—Finish the earthing-up of Asparagus beds as speedily as possible; continue to cut Seakale as it appears, but do not fill up the broken parts of the ridges after the crowns have been cut. Weed Onions sown in lines and beds, but permit those sown broadcast to advance a little before they are touched; immediately, however, they can be well discerned, the short, narrow hand-hoes may be set at work amongst them. Sow Spinach broadcast where room is to spare, also Parsley in beds, if not already done. Prepare for sowing the crop of Beet and Mangolds, and also Wallflowers, if not already done. Fully expose the young Leeks in frames, also knotted Marjoram, both of which may soon be transplanted. If any have tender fruits on walls, protection for them should be provided. Finish grafting at once, especially that of stone-fruit trees.

## COVENT GARDEN MARKET.

APRIL 18TH.

**Flowers.**—Of these the supply is good and the demand brisk, yet last week was the recognised one for extensive business, as growers annually look forward to Easter week, in which they know that the demand for cut flowers and plants in pots for church decoration is great, therefore they enlarge their supply and increase their price accordingly. Pelargoniums, Roses, Hoteias, Calceolarias, Cinerarias, Cytisus, Ferns, &c., constitute the bulk of the pot plants. Cut flowers comprise seasonable blooms from the stove, conservatory, and open air. The usual supply of spring flower roots, climbing plants, and miscellaneous subjects continues to be furnished in abundance.

**Fruit and Vegetables.**—The supply of St. Michael's Pines is nearly over, and home-grown ones of good quality are scarce for the season. New English Grapes are good, and tolerably plentiful; there is yet a considerable quantity of old ones of excellent quality in the market. English-grown Peaches of excellent quality have just appeared. French Asparagus of wonderful size has just arrived, and likewise good supplies of French Beans, Broad Beans, and saladings.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Cobs, per lb., 2s. to 2s. 6d.; Grapes, hotbouse, per lb., 15s. to 30s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 4s. to 10s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 6s. to 10s.; Strawberries, per oz., 9d. to 1s. 6d.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 5s. to 10s.; French, 10s. to 30s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, young, 1s. 6d., old 6d.; Cauliflower, per doz., 3s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 6d. to 2s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz. 1s. to 2s.; Mushroom, per pottle, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 3s. to 6s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 4s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 5s. to 8s.; Potatoes, per bushel, 4s. to 8s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsify, do., 1s. to 1s. 6d.; Savoys, per doz., 2s. to 3s.; Scorzonera, per bundle, 1s.; Seakale, per basket, 1s. to 2s.; Shallots, per lb., 8d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, old, per bunch, 3d. to 6d., young do. 2s.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### BITTON.

FROM the earliest issues of "Sweet's British Flower Garden" down to the latest numbers of THE GARDEN, the names Ellacombe and Bitton frequently occur in gardening literature, and the Bitton collection is known to most lovers of hardy plants as one of the most interesting in Britain. To satisfy a long-felt wish, and in response to repeated kind invitations, I at last found myself there on the 12th inst. The sunless winter has caused a late spring, and a cold cloudy day dims the beauty of the spring flowers. Only a small part of the collection is as yet visible above-ground, and therefore it is far from being a favourable time to see the garden; but perhaps the paucity of kinds may be compensated for by the sight of novelties hardy enough to blossom so early after such a season. It is a good garden where one makes new friends or sees old rarities thriving apace, and here, flourishing by the hall door, is one of those beautiful evergreens which I last saw on the foothills of the Sierras—like Laurels standing for shade near the Pines, and helping, with the noble evergreen Oaks of the hill country, to make a glorious evergreen copse beneath the gigantic trees. It is the Californian Laurel (*Tetranthera californica*), which has proved perfectly hardy at Bitton for the past ten years, and is one of the handsomest evergreen shrubs in the country. Though quite distinct from our Sweet Bay, it is somewhat like it in aspect, and has a powerful odour. It is sometimes called *Laurus regalis*. As there are many other districts as favourable to its growth as this part of Gloucestershire, we hope it may soon be extensively planted. But what is this delicate odour, like that of the Violet only in one thing—that it lives in the chilly air? It is our old friend the Indian *Daphne* (*D. indica rubra*), which is here in perfect health, growing against a sunny wall. It has been in flower throughout the spring. In all the milder parts of the country it would be very desirable to try to establish this fragrant plant out of doors. The specimen in the open air here is much healthier than the sickly individuals so often seen in greenhouses. The Olive thrives here as a wall plant, and our old greenhouse friend, the sweet *Mandevilla*, grows and flowers well in the open air. Fine specimens of the variegated *Yucca aloifolia* are in perfect health in the open borders, the only "protection" used being a broad board overhead, to throw off the rain and snow during winter. It is doubtful if this is necessary. Such a remarkable plant and one so unlike anything else we have in the open air, should be tried oftener out of doors.

Although here one often meets with very rare shrubs and climbers, it is for its herbaceous and alpine plants that the garden is most celebrated. Of all private collections of these plants this has been the most enduring, so far as we know. Few of the old collections survived the bedding fever; most of our present famous ones date since that period, but hardy plants in rich variety have been grown here for more than half a century by the Rev. Mr. Ellacombe and his father, the former vicar, who is yet, by the way, cultivating a good collection in Devonshire. Probably some of the tufts we now admire furnished specimens to Sweet more than forty years ago. This, at least, is the case with that mass of the scarce double *Narcissus cernuus*. The garden has long been celebrated for its Daffodils, many of which are now in blossom; the Paper-white and some of the forms of *N. tazetta* being particularly beautiful.

Among the many Irises grown in the garden, *I. stylosa* deserves special commendation. This is a handsome medium-sized Algerian species, which has the invaluable property of flowering in winter. Spring-flowering Irises we have of which we are proud, but this is an acquisition indeed. Inelement as the day and the season are, in addition to the flowers seen in gardens where spring flowers are grown, we may name a few less common as having been in flower on the 12th. This may serve to remind readers fond of early flowers of what to add to their gardens. The quaint and singular *Carex Fraseri* is in blossom, and so is the equally quaint but

fine *Podophyllum Emodi*; while the large flowers of the beautiful North American *Trillium grandiflorum* are just on the point of expanding. The modest little *Dondia*, with its welcome cushions of pale yellow, is outshone by the yellow buds of the dwarf Poppy-like *Stylophorum*. That curious form of the wood *Anemone bracteata* is in bloom, of course, and so is the blue wood *Anemone*, one of the most charming of all spring flowers. It is simply a bluish form of our common British wood *Anemone*. Larger than the graceful bells of the common but beautiful Snake's-head *Fritillaria* are those of *F. latifolia*; while the *Hutchinsia* makes the ground sparkle with snowy-white stars, like its ally *Cardamine trifolia*. The flowers of *Melanthus major* are just ready to open, and *Rubus spectabilis* (a showy, easily-grown, early shrub) is a worthy associate of the flowering Currant. The Blood-root (*Sanguinaria*), which grows thick as Daisies under the trees in Canada, has for its companion the interesting Twin-leaf (*Jeffersonia*), also from North America, and our brilliant and brave little early friends, the hardy *Cyclamens*, are not far away from the Mandrake, with its mournfully-hued blooms. The early but sad-looking *Scopolia*, the soft Italian and other Squills, are rivalled in beauty by the *Tritelecia*s, white and pale blue; and the common annual *Claytonia* of our gardens is here accompanied by the true "spring beauty" of the American woods (*Claytonia virginica*), while our own Pasque-flower is almost surpassed in beauty by a dense tuft of the soft purple of *Anemone patens*, wrapped in down, as it were, to guard it from the chilly breeze; and, finally, the common Crucifers are associated with the cheerful blossoms of the neglected *Dentarias*.

There is a fine collection of Sun Roses here; the sun must shine, however, before they give us their beauty. Let us hope that this and like collections will sow the seed of a taste for these lovely and brilliant shrubs, now utterly neglected. *Styrax officinalis* is a great favourite here. The flowers are like those of Orange blossoms, and smell like them. The Californian *Diplacus glutinosus* is quite hardy here. The *Heuchera*s, being evergreen and handsome in foliage, are employed for filling the corners of beds and places it is desired to furnish in winter. *Miehauxia campanuloides* "sows itself" here, and grows with great vigour. The handsome and distinct *Chamaepeuce diacantha* also comes up self-sown, and may be seen here and there coming up as the "Scotch Thistle" so often does. The garden is rich in Yuccas, but having given a cut showing a fine group of these in full bloom here, at p. 427, vol. ii., we will now pass them by. On the walls of the garden two very good plants are established, the Cheddar Pink and, more curious still, *Agrostemma Flos Jovis*. In this position this fine plant, which so often damps off on level ground, thrives well and flowers beautifully. It need hardly be added that the Cheddar Pink is seen to greatest perfection on walls.

Very dwarf shrubs, such as the minute Willows, *Cotoneaster congesta*, *Pernettya arctica*, and other very dwarf kinds, are favourites for the rock garden, on which also the little antarctic Beech finds a home. A tuft of *Cypripedium pubescens* in a border here bears about fifty flowers at a time. There is a good collection of hardy Oxalises, of which *O. venusta*, *O. bipunctata*, *O. floribunda*, *O. lobata*, *O. spectabilis*, *O. Deppei*, and *O. lasiandra* are a few of the most ornamental kinds. The merits of the species are too little known. There is also a large collection of the herbaceous *Pæonies*, distinct species, of which it may be useful to record that the earliest is *P. cretica* and the best *P. lobata*. British Orchids occur often in the borders. There is not much difficulty in cultivating them, but the *Ophrys* section do not endure more than two or three years. One of the handsomest evergreens we have seen for a long time is a fine specimen of the interesting *Cochinical Oak* (*Quercus pseudo-cocciferus*). This would appear to be a much-neglected tree. Among the Bamboos grown here, *Bambusa Ragamouski*, a dwarf but fine-leaved and glossy kind, seems the healthiest and the hardiest. The fine and scarce *Tropæolum polyphyllum* grows like a weed in the border here; so does the Cape *Encomis regia*. A *Wellingtonia*, one of many struck from cuttings by Mr. Ellacombe, is now over 18 feet high. There is a good specimen of this tree here 35 feet high. Other features of this place we shall allude to hereafter.

## NOTES OF THE WEEK.

— It is the fashion to extol the brightly coloured double Peaches, and there are no shrubs more worthy of culture, but the double white kind now speckled all over with the snowiest blooms, seems to us the loveliest of all. Even where the various double Cherries are seen in all their beauty, this should have a choice position.

— Among the fairest ornaments of the outdoor garden now in bloom are *Corydalis nobilis* and *C. bracteata*. The first has the largest head of flowers and the richest colour, the last a beautiful lemon-coloured hue. Both should be multiplied as much as possible for the embellishment of our spring gardens.

— The most refreshing garden retreat in London just now is the Botanic Gardens in the Regent's Park. This is mainly owing to the sweet open spread of turf, the happy "natural" design, and the bursting into beauty of the deciduous trees and shrubs. A roomy boathouse for tropical, medicinal, and economical plants is being built, and the medical garden in the open air has been changed for the better. The needless prominence given to certain meteorological apparatus causes, however, certain ugly blemishes from important points of view.

— We were glad to notice some of the best of the alpine Primulas and Androsaces flowering well in the open borders at Kew the other day. The soil in which they grow is nearly paved with smallish stones, which do good in preventing evaporation. Hitherto it has been too much the fashion at Kew to keep the choicer alpine plants in cold frames and pits, where they are little seen and do not thrive so well as when properly treated in the open air.

— The vivid purple flowers of *Helleborus caucasicus* (var. *colchicus*), if not among the showiest spring flowers now in bloom, are far from being among the least beautiful. This, among the latest of the "Christmas Roses," well deserves a place in every garden where April flowers are grown. It would do nicely on the margins of clumps and beds of small shrubs.

— Few textile plants of acknowledged value have had greater difficulties to contend against than *Sida retusa*, but, thanks to the perseverance of Mr. Kennedy, of Covent Garden, it is now likely to come into the English market. It is a Queensland Mallow-wort, and grows there in dense masses from 4 to 6 feet in height. When once established, it spreads with great rapidity, and it is quite within the mark to say that thousands of tons of it could be cut at any time, provided sufficient remuneration was offered for the work. Its fibre, which is of great strength and beauty, is worth from £25 to £30 a ton.

— DR. F. ARNOLD LEES and Mr. T. B. Blow propose, says *Nature*, to form a club under the name of the Botanical Locality Record Club, the object of which shall be to collect and keep a record of the exact localities of all the rarer British plants, with the dates of the latest observance of each, to be published yearly at the end of each season. The yearly report, containing not only a detailed list of the localities, but also a geographical summary of each year's work, is to be published and distributed only to members of the club, and to certain learned societies; to the former a subscription of 5s. will be charged. The names of botanists desiring to become members are to be forwarded to Mr. T. B. Blow, Welwyn, Hertfordshire.

— We are indebted to Mr. Luscombe, of Combe Royal, Kingsbridge, for an opportunity of inspecting many lovely heads of *Rhododendron* blooms, that have been sent to us as illustrations of the way in which such plants flower out of doors at this season in that part of Devon. Foremost amongst them may be mentioned the Sikkim species *R. Thomsoni*, a beautiful kind with obovate leaves, glossy deep green above, and silvery beneath, and with waxy purplish crimson flowers not unlike those of *Lapageria rosea*. With this came another Sikkim species bearing a compact truss of medium sized purplish-lilac flowers; another species from the same district bore a profusion of blooms of the most brilliant crimson. Others again varied in colour, from the brightest crimson scarlet to pure white, the latter in one instance being deliciously sweet scented. Altogether the collection was one of great interest and beauty.

— THE new council of the Royal Horticultural Society has entered into the following temporary arrangement with the Exhibition Commissioners:—The fellows and their friends to retain the private enjoyment of the gardens and conservatory. The Exhibition visitors not to enter without the usual payment of the day. The lower quadrant arcades to be for the fellows and their friends only. The upper story of quadrant arcades, with a communication across the back of the conservatory, will be entirely fenced off for the Exhibition visitors. The commissioners to open forthwith, at their own expense, a new entrance for the society at the south-west side,

and to allow the society to use, without payment, until the 1st April, 1874, the north-western and north-eastern entrances in Prince's Gate and Queen's Gate respectively. The society to permit the Exhibition visitors, until 1st November, 1873, a passage way across the gardens, so as not to interfere with the privacy and freedom of the fellows and their friends. The fellows and their friends and debenture-holders to have a joint right with the Exhibition visitors of using the central arcades. The commissioners to pay £1,000 in cash before November, 1873, to the Royal Horticultural Society.

— THE Manley Hall collection of plants, just sold, realised the sum of £5,586. The Orchids alone fetched £4,361, the rest being for miscellaneous stove and greenhouse plants. The entire number of lots sold was 1,623.

— FRENCH sailors are said to have introduced a new luxury into this country. Garden snails, already prepared and cooked, are now being publicly sold in the streets of Gloucester, and they appear to find ready customers.

— ON light warm soils the lovely *Lithospermum prostratum* is now conspicuous for its beauty, even among the showily-beautiful flowers of spring. The blossoms, however, do not come out so densely as they do in early summer.

— A CHARMING double blossomed variety of the common garden Anemone has just been sent to us by the Rev. Mr. Ellacombe, of Bitton. Its colour is scarlet of the most brilliant kind, and it is as double as a Pomponé Chrysanthemum.

— A good tuft of the rare *Puschkinia scilloides*, a beautiful hardy bulb, is now blooming finely in the open grounds at Kew. This plant grows about 6 inches high, producing racemes of delicate blue and white flowers, and should have a place in all collections of hardy bulbs, either in borders or on rockwork.

— SOME noble specimens of hardy Magnolias are now, and have been for some time past, in great beauty at Messrs. Rollisson's Nursery at Tooting. One old specimen stretches its arms over the Tooting road, and scatters its great white leathery petals over the footway.

— THE rare and remarkable *Saxifraga peltata*, quite a giant among Saxifrages, is now in flower in the Stansted Park Nursery, Forest Hill. It belongs to the large-foliaged section, the leaves when fully developed being as large as those of *Rhinbarb*. It is, therefore, as remarkable for its fine foliage as for its flowers, which are rose-coloured.

— AT a sale of Orchids imported from New Granada and the East Indies, which took place at Stevens' the other day, several lots of the new *Masdevallia elephanteiceps* were sold at from £3 10s. to £6 12s. 6d. per lot. This species, which is said to have magnificent flowers, is very difficult to import, the few lots offered on this occasion being all that reached England alive out of a thousand that were shipped. Single clumps of *Masdevallia polyantha*, sold at the same time, fetched from £3 5s. to £4 a-piece; some of *M. ignea* as much as £6 6s.; and a few lots of *Oncoglossum Blandianum* from £2 5s. to £3. Clumps of *Utricularia montana* realised about two guineas each; others of *Oncidium cucullatum* fetched from £2 5s. to £2 10s. The total amount realised for 588 lots was £823.

— WE have received from Messrs. E. G. Henderson & Son coloured illustrations of some of their new bedding plants. They consist of *Sedum acre elegans*, a yellow variegated little gem, and Golden Fleece Thyme, which promises to be one of our most popular bedding plants, being dwarf and compact, and of a striking colour; also *Cineraria ceratophylla*, a compact, very white, beautifully lacinated-leaved plant, and two kinds of *Alternantheras*, viz., *A. amoena spectabilis*, a brilliantly-coloured, robust kind, and *A. paronychioides major*, also a strong-growing and highly-coloured variety. The most striking plant of all, however, is *Lobelia Mazarine Gem*, a moderately dwarf-growing, compact kind, with large and showy, intense blue flowers, each having a conspicuous white eye, and produced in the greatest profusion.

— THE first idea of raising Briar stocks from seed has been claimed by M. Rivière for M. Guillot, a Rose grower at Lyons, who has raised his stocks in this way for the last twenty years. To M. Guillot, also, belongs the credit of ex-cogitating a means of preventing his Briars from producing suckers. Reflecting that suckers are nothing more than subterranean branches, which, like all other branches, must issue from the axil of a leaf, he considered that by inserting the bud on the part of the stem below the axils of the lowest or cotyledonous leaves (which are usually under the surface of the soil) he would deprive the stock of all power to produce suckers in future. In practice, M. Guillot simply removes the soil from about the lower part of the stock and inserts the bud close to the neck. The result is that his Roses seldom or never show suckers, and if one chances to appear, it is sure to be from the buried part of the Rose graft, and not from the Briar stock.

## THE INDOOR GARDEN.

## LONG-TAILED LADY'S SLIPPER.

(CYPRIPEDIUM CAUDATUM.)

THIS is not only one of the most remarkable of Lady's Slippers, but also one of the most singular plants in cultivation. Its narrow petals are but an inch or two long when the flower-buds first expand, but they gradually extend until, in ten or twelve days, their length varies from 18 inches to nearly a yard! This remarkable species is a native of Bolivia, and a variety of it is also found on the Peruvian Andes. Its foliage is about a foot in length and of a bright green colour. The flowers are produced two and three together on a stout scape from a foot to 16 inches in height; the sepals are of a pale yellowish green, streaked with dark green, while the lip, which is large and pouch-shaped, is of a yellow and rosy-purple colour, the interior being white spotted with clear purple. The petals

Cypripedium (selenipedium) caudatum.

are of a yellowish green colour, striped with reddish-purple. It grows freely in an open well drained compost of turfy loam and peat, surfaced with fresh sphagnum. Well-grown plants of it flower regularly every year, and last a month or six weeks in perfection. A specimen of this plant in Mr. Salt's collection at Fernhurst has borne flowers with tails 32 inches in length. This, like its congener *C. villosum*, is a fresh-looking plant when not in flower, and does well in an intermediate house. The peculiar long-tailed *Uropedium Lindenii* is in all probability nothing more than an abnormal form of this species, from which it differs in having the saccate lip transformed into an elongated petaloid appendage. In habit the two plants are identical. F. W. B.

## THE MIMULUS.

THE large-flowering varieties of *Mimulus*, having yellow flowers variously spotted and blotched with dark, make charming plants for the decoration of the greenhouse and conservatory when grown in pots. There are also newer varieties, giving different shades of ground-colour, more or less, however, retaining the original yellow; but, instead of being formally blotched, they are densely spotted or mottled, or handsomely pencilled, in the form of stripes and markings. About ten years ago Messrs. Veitch and Sons introduced from Chili *Mimulus cupreus*, a dwarf, hardy, and very pretty border plant, intermediate in size between *M. luteus* and *M. moschatus*, and having a compact growth more rigid in the habit than the common kinds. This was too small in itself to be of much use for pot culture, much less for growth in the open air; but it was invaluable for cross-breeding purposes, and the large-flowering forms of *M. luteus* being crossed with *M. cupreus*, and *vice versa*, intermediate types were the result, having larger flowers than the imported species, marked in a similar manner. These received various specific names, such as *M. maculosus*, *M. tigrinus*, and so on, and have proved very useful and effective flowering plants. These, again, fertilised with *M. cupreus*, produced flowers diversely marked, and having more of that bronzy-red peculiar to the Chilean species; the colour and markings are extremely novel, the palate of the flowers being in some instances quite richly spotted. Some of the seedling forms lately obtained showed a tendency to produce one flower issuing from the mouth of the other, like the well-known hose-in-hose *Polyanthus*. This characteristic, by means of careful selection, became fixed and permanent; and we have now a strain of "semi-duplex" flowers, as they are termed. They are certainly curious, but not so attractive as the single flowers. Some seed sown early in the spring will give an abundance of plants for the summer. In a fine sandy soil and a temperature of 60° the seedling plants will soon appear above ground. The *Mimulus* is a plant of such easy growth that it simply wants potting in rich light soil to have plants a good size for blooming in the greenhouse or window of a sitting room, or planted out in the open ground. The plants are somewhat fragile, and a heavy shower of rain soon beats them down; but an hour or two of sunshine remedies matters with surprising quickness, and soon the plants are aglow with gay blossoms. Any strongly marked and attractive variety it may seem desirable to preserve can be propagated by offsets from the roots, or by cuttings. The old-fashioned plan of gradually withholding water when the plants had done flowering, and suffering them to dry off, and then laying them by all the winter till they begin to grow in spring, and could be divided at the roots, is as applicable now as it was fifty years ago. It is also both an easy and a reliable process. There are representatives of this gay genus yet well worthy of a place in our plant houses; and the tendency of the present time is to restore the *Mimulus*, among other old-fashioned plants, to the popular favour it so richly deserves. Out of doors the varieties of *Mimulus* best enjoy the margin of the Rhododendron beds, or any slightly shaded position where there is a light moist soil. The Musk plant (*M. moschatus*) cannot and never will be spared. It is as much interwoven, with our home life as any other plant; and at exhibitions of cottagers' and window plants generally, the Musk is always seen, invariably nicely grown and tenderly cared for. Suitable alike for cultivation in the open air or in pots, it is when grown in the latter that it is seen best. It is fond of a rich soil, plenty of water, and an abundance of air; under these simple conditions, excellent specimens can be grown even in the window of a sitting room. Some cottagers in the midland districts grow the Musk remarkably well by planting it at the bottom of a pot, and as the branches grow filling up with rich soil, which causes the growing shoots to throw out fresh supplies of rootlets. Selection of old large-flowering spotted varieties:—Beauty, Etna, C. W. Cowan, Dr. Greville, Clara, Grand Sultan, Hugh Adair, Gaiety, Madame Mieliez, The Bride, Sunset, and Nymph. Selection of the Maculosus strain:—Albus elegantissimus, Aurantiacens splendens, Festoon, Gazelle, Inimitable, Leopardinus, Meteor, Orientalis, Sylva, and Vulcan. Quo.

## WATERING PLANTS.\*

OF the many operations the gardener has to perform in the cultivation of plants whose roots are confined in the limits of an ordinary pot or similar appliance, there is one that demands his daily and unremitting attention—namely, the application of water—the proper performance of which I may term the sheet anchor of successful plant growing. Let the soil be of the best possible description, according to the requirements of any given variety or species of plant; let the temperature, the light, ventilation, and other con-

\* Read by Mr. Baines, at a horticultural meeting in Liverpool.

ditions be all that is requisite,—if it is not properly treated in respect to water, disappointment is certain speedily to follow. Yet there are numbers to be found who form a different opinion, and who seem to think that if the soil in which the roots are placed is of the right description, all ought to go on satisfactorily. How often do we hear the question put, in reference to some particular plant, In what is it potted? And when the information is acquired we see the look of satisfaction, as much as to say, "That is the secret." I do not ignore the necessity of suitable soil, but simply put it as a secondary consideration to the all-important operation of watering; and what renders the matter more complicated is the difficulty of giving either precise verbal or written directions upon the subject.

Taken collectively, the plants that are found in the lower regions of tropical countries—such as are met with in our stoves and hot-houses—are not impatient of slight excesses of moisture, being subject to such in their native countries. The different varieties of *Dipladenia*, however, are an exception, some of which absolutely require a drier state of soil than any other blooming plants in cultivation. It is to the plants from the more temperate regions of the Cape and New Holland that I would more particularly allude—to the *Aphelexes*, *Hedaromas*, *Boronias*, *Ericas*, *Leschenanlias*, *Pimoleas*, *Gompholobiums*, *Aerophyllums*, *Dracophyllums*, &c., &c. It is generally admitted that the successful cultivation of these plants taxes the gardener's skill and attention to a much greater extent than anything else which comes under his charge, for many of them require years of close and unremitting attention to grow them into specimens, and a single day's neglect is often irreparable. What makes their culture more difficult is that almost every variety, in each species requires somewhat different treatment. Hence it is that, amongst those who have been the most successful in their culture, there are few who have been able to grow the whole group well; and as all thrive in nearly the same description of soil, with a slight difference in temperature, I conclude that the variable success of cultivators with these plants generally arises from the different conditions observed as to water. With these, as with other plants, it is necessary when water is given to use sufficient to moisten all the soil. But in this question of water the great difficulty is to arrive at what degree of dryness the soil ought to be in before water is given. If the same conditions in this respect would answer for all, there would not be much difficulty; but many of the varieties, even of the same species, of the above and other families of plants, require wide differences in treatment. For instance, if some were allowed to get dry before water is given, as it is absolutely necessary for others to become, disease or death would soon follow. This elicits the fact that knowledge of when and how to water can only be acquired by long and observant study. There is one moderately safe rule to go by—plants with fine roots, small leaves, and very hard wood, are comparatively slow growers, and never ought to be watered until the soil has got to that state in which it would not be safe longer to withhold it. If plants of this description ever flag in the least they rarely recover; therefore he who would be successful must be ever vigilant.

There is yet one other consideration, a most important one, bearing upon this subject. It is involved in the question, What are the conditions as to moisture, atmospheric and otherwise, under which any given plant is found in its native habitat? And this points to the necessity of gardeners studying the geographical distribution of the vegetable kingdom. Taken in a general sense, if there is one subject more than any other with which gardeners ought to be thoroughly conversant, it is this. Even in the case of the most common plant such knowledge will be an assistance; for although it is possible to grow a plant through following the routine of blind practice, still he is much more likely to succeed who is properly conversant with the natural conditions under which the plant is found in its native country. This has especial reference to the subject we have under consideration. To say that a plant comes from India, South America, or elsewhere, is to say very little, inasmuch as the altitude at which a plant is found in any country makes a wonderful difference as regards its requirements, especially in the matter of water. For although it is possible, and often necessary in some measure, to depart from the conditions under which a plant is found in its native country, still, in respect to water, its requirements ever remain much the same, and ever must, unless its nature were to become changed under cultivation, which I hold to be, to any great extent, impossible. By way of illustration, I may mention the difficulty of fruiting the Apricot in pots experienced by those who first practised that system of fruit culture. The plant is indigenous to Armenia, near the foot of Mount Ararat, and is continually, during the spring and blooming season, under the influence of the cool moist atmosphere wafted from the perpetual snow-clad summit of the neighbouring mount; and consequently, when submitted to culture under glass, the atmosphere that suited the Peach and Nectarine was too dry for the Apricot, and the cause of failure was therefore no

mystery. Again, take for example those beautiful Orchids found in the hill districts of India, such, for instance, as the lovely *Dendrobium Devonianum*, from the Khasian Hills, and *Cologyne cristata*, from the high regions of Nepal. These and others from the same and similar elevated districts require double the quantity of water necessary for plants found nearer the sea-level. Collectors of late years give us much more detailed accounts as to the conditions under which the plants they have discovered are found than used to be the case. Such, and all other available information on the subject, ought to be well considered by all who would wish to succeed in gardening matters at the present day; for the man who has his mind well stored with such knowledge has an immeasurable advantage over one who is ignorant on the subject. This appears the more obvious when we consider what the gardener at the present day is expected to be able to perform. We have in Britain over 30,000 species of plants, native and exotic, the great majority, of course, possessing nothing more than botanical interest; but among them are thousands which the gardener is expected to be able to grow successfully. I admit that it is possible for a man to grow any particular plant well without possessing the knowledge in question, yet, as I have stated, he is much more likely to succeed with the help of such knowledge. In fact, it may be said, that with a general knowledge of vegetable physiology, the gardener's every-day operations are rendered more certain as to their results than they otherwise could be, as it enables him to exercise those great essentials to success, the ability to adapt himself and his plants to circumstances. From what I have advanced it will be seen that, in successful plant-culture, I consider the skilful performance of the operation of watering of equal importance with all other operations collectively; and I consider the careful study of the actual condition under which plants are found in their native habitats as furnishing the only safe rule for our guidance in such matters.

#### TEA ROSE CULTURE IN WINTER.

PROBABLY few of our readers are aware of the extent to which Tea Roses are grown in America in winter, to supply the immense demand for them in bouquets and in every kind of indoor decoration. We failed to find a nursery in more than one large city in America, but never visited one where there was not an establishment for the growth of cut flowers, chiefly Roses. In some of the best establishments we saw the Tea Roses planted out and treated much as Vines or Peaches are treated in a good forcing garden in England. The following article in the *Agriculturist*, written by Mr. Peter Henderson, the largest grower near New York, gives the most improved mode of culture:—

Recent experiments on a large scale have shown that the old system of growing the plants in pots or tubs is not so good as to plant them out on a bench or border prepared specially for the purpose. Last season, in August, we planted out a bed 500 feet in length by 8 in width, with large plants that had been forced in pots the previous season. They were then covered with mildew, and were a sorry-looking lot, but by the middle of September the mildew had entirely disappeared, and we managed to keep them in vigorous health, entirely clear from mildew or other disease, until the following June. The bed in which they are planted is a boarded bench or table, having only 7 or 8 inches depth of soil. This, however, will not be enough to carry them through more than another season, and it will be necessary to increase the depth of soil by lowering this temporary bench to a bed prepared under it. We find that the size of the buds is much increased when the Roses are planted in solid beds. Acting on this knowledge, we are this season erecting a structure 40 feet by 100 feet, and have prepared the Rose-beds as follows: We have run a brick wall around the 8-foot-wide beds 20 inches in height, with two rows of "pigeon-holes" at the bottom, for the double purpose of giving perfect drainage and admitting air to the roots. The soil used is equal parts sod, scrapings from a paved street, and well-rotted cow-manure, all thoroughly mixed together. The bottom of the bed is rounded slightly from the centre to the sides, so that the surplus water may pass off freely; and to prevent the roots from striking down into the cold subsoil we have cemented the bottom of the bed. In fact, the manner of preparation of the bed or border is exactly similar to that for a Vinery border, except that our Rose borders are inside the house, and elevated 20 inches above the walks. I have given the composition of the soil we are using, and which we know to be excellent, but where street clearings are not attainable, two parts sod and one manure will probably do quite as well. We are planting out our new houses exclusively with Safranot (deep fawn colour), except at each pillar we plant alternately a Maréchal Niel (golden yellow) and a Climbing Agrippina (dark crimson). The Safranot

will be the main crop, as we find it so far the most profitable and satisfactory. The houses now erecting are span-roofed, equal on each side, and facing east and west. This style was necessary from the position in which we were compelled to place them, but for choice we still prefer the half-span style. There is a general impression that the glass should be stripped from the Rose beds in summer. This, we believe, is not only useless but injurious. In the vicinity of Boston, where Roses are grown better perhaps than in any other part of the country, the Roso houses have nearly all fixed roofs, except certain sashes for ventilation, and the plants, which in many of them have been growing for three or four years, are now immense bushes in the most perfect health. But to keep them in health of course requires work. The plants must be syringed freely twice a day, and the paths freely watered, to keep a moist atmosphere in the house. To modify the sun's rays, the glass should be painted with raw oil from June 1st to September 1st. Oil we find to make the best shading for this purpose, whitewash darkening too much. In painting the glass with oil we use a sponge attached to a stick, and remove it by sponging it off with boiling water. The leading varieties grown have been Safrano and Bon Silene, with lesser quantities of Lamarque, Maréchal Niel, and Isabella Sprunt, as few others are sufficiently prolific flowerers to justify their being grown for buds in winter. There has been a want of a deep crimson shade, which I am in hopes the Climbing Agrippina will supply. The form and colouring of the bud is splendid, but we have not yet had an opportunity of testing its flowering qualities. The temperature requires to be raised somewhat to suit the nature of the different sorts; for example, if Maréchal Niel and Bon Silene and Safrano and Climbing Agrippina are to be grown in the same house, and there is any difference in the temperature of one end over the other, we would plant the first two sorts in the hottest end, as they require a temperature of 65° at night, while the other two will do well at 60°.

### ACACIA RICEANA.

This beautiful species of Acacia, which has on several occasions been alluded to in THE GARDEN, has a habit of growth some-

Acacia Riceana.

thing like that of a Weeping Willow. Its deep green foliage, its long whip-like pendent branches clothed with golden flowers, the facility with which it can be trained over columns and arches, and the length of time during which it remains in flower, render it one of the most desirable acquisitions for a conservatory. A fine bush of it grew in the great curvilinear glass-house at Chiswick, before it was converted into a vinery. The seeds should be soaked in warm water twenty-four hours before sowing, otherwise they will be a long time germinating. A fine plant of it is now coming into flower in the winter garden at Kew.

**Jointing Hot-water Pipes** (see p. 312).—India-rubber joints for hot-water pipes are but of little use; they only last about two years. I never use them. If the pressure is not very great, red and white lead mixed, and yam, make the best joints. If the pressure is great, iron cement properly mixed is best.—D.

## THE FLOWER GARDEN.

### NEW, RARE, OR NEGLECTED ALPINE PLANTS.

(Continued from p. 297.)

**ACHILLEA AIZOON** (Anthemis Aizoon) Everlasting Achillea.—A beautiful silvery-leaved plant from the sub-alpine districts of Northern Greece, 4 to 7 inches high, with pure white flowers (resembling perfectly white Daisies), which appear early in summer. The leaves are tongue-shaped or lance-shaped, and covered with white down, the lower ones crowded. This is a very neat and distinct-looking plant, and easy of cultivation in light soil on rock-work or in warm borders.

**BRODLEA COCCINEA** (Crimson-flowered Brodiaea).—A very beautiful Californian bulbous plant of the Lily family, with a flower-scape from 2 to 3 feet in height, bearing in summer a dense terminal umbel of rich magenta-erimson pendent tubular flowers; each flower being from 1½ to 2 inches long, yellow at the extremity, and with reflexed green tips; the umbel consisting of five to twenty blossoms according to the vigour of the plant. The leaves are linear, channeled, lax, and nearly as long as the flower-scape. This very charming plant should be planted in a warm position in the rock-garden or choice mixed border among select plants, and in warm sandy loam.

**CLAYTONIA VIRGINICA** (Spring Beauty).—A handsome American plant of the Portulacaceæ or Purslane family, sending up in early spring simple stems bearing a pair of opposite linear lance-shaped leaves from 3 to 6 inches long, and a loose raceme of pretty rose-coloured flowers marked with deeper veins, which, unlike the flowers of most of the species of this family, remain open for more than one day. Suited for the rock-garden or borders, in loam and leaf-mould.

**DAPHNE STRIATA** (Striated Daphne).—A sweet-scented hardy trailing species, resembling *D. Genkwa*, but somewhat more shrubby. It forms dense, twiggly, spreading masses, 1 to 3 feet across, which, in June and July, are covered with a profusion of rosy-purple, carnation-scented, tubular flowers, growing in clusters. The trailing and freely-spreading habit of this plant recommend it as an excellent subject for covering bare parts of rock-work. A native of France.

**DIANTHUS FISCHERI** (Fischer's Dianthus).—A very beautiful, and as yet rare, species from Russia, 7 to 10 inches high; blooms in summer; flowers numerous, of a light rose-colour, with the petals much cut or feathery at the edges, in closely-set fascicles; leaves lance-shaped, stiff, with a single vein on the upper side. Deserves a good position in the rock-garden, in moist, sandy, or gritty loam.

**DRABA CILIATA** (Eye-lashed Whitlow Grass).—This is really a good white Draba, not unlike a diminutive specimen of *Arabis albida*. The leaves are broadly spoon-shaped, sparsely but distinctly ciliated, in loose rosettes. Flowers in early spring; pure white, about eight on a stem; the whole plant when in bloom not being more than 2 inches high. Mountains of Croatia and Carniola.

**EPILOBIUM OBCORDATUM** (Dwarf Californian Willow Herb).—This, which is by far the finest of the alpine Willow-herbs, has been recently introduced from the Rocky Mountains of North America. It forms handsome little shrub-like tufts, 3 or 4 inches high, and flowers late in summer, producing large rosy-erimson blossoms, resembling those of *Clarkia integrifolia*. The leaves are small, smooth, and roundish, closely set on the erect stems, and the plant, even when not in flower, has a remarkably neat and distinct appearance from the foliage alone. Coming from the summit of the Sierra Nevada, it is perfectly hardy, and will prove one of the most valuable and attractive of rock-plants. It is also an exquisite pot-plant, and thrives to perfection in ordinary peaty loam.

**ERYTHRONIUM GIGANTEUM** (Gigantic Dog's-tooth Violet).—A very large species from N. America, growing from 9 to 13 inches high, and bearing from three to ten large flowers on one stalk, arranged in a branching and somewhat confluent spike, each flower 3 inches or more across, and usually of a creamy white, shaded with delicate pink or purple. There is great variety, however, in the colour. In different districts plants are found with pure white, with light lemon-yellow, and with clear red purple flowers. The plant continues in bloom through February, March, and April, and the flowers are very handsome, the petals being broad and well expanded.

The leaves are blotched and marbled with purplish-brown. Same culture and positions as for the common Dog's-tooth Violet.

**EDRAIANTHUS PUMILIO** (Silvery Harebell).—A singularly pretty and minute rock-plant, with foliage resembling that of a dwarf tufted Pink, hoary and silvery, with adpressed hairs on the upper side, very finely ciliated at the edges, the under sides quite smooth, shining, and dark green. The flowers, about an inch long, are almost seated among the leaves (the whole plant not being more than 2 inches high), of a pure purplish blue, vasiform, cut into segments for about one-third of their length, and opening in May. Croatia. A gem for the rock-garden, thriving in moist loam with abundance of sand or grit, and well suited for association with the alpine Forget-me-not and other dwarf and choice May-flowering rock-plants. Easily raised from seed.

**GALANTHUS IMPERATI** (Imperati's Snowdrop).—This is a very large species of Snowdrop, found on mountains in that part of Italy which was lately called the Kingdom of Naples. It resembles our common Snowdrop, but is double the size in all its parts, and flowers later; one of the external divisions of the flower, also, is larger than the others. The leaves are very broad and long, but not plicate at the margin, like those of the great Crimean Snowdrop, *G. plicatus*. It flowers ten days to a fortnight earlier than the latter. This very desirable species is at present scarce in this country; but we have no doubt that a demand for it would stimulate our nurserymen to provide themselves with a supply.

**GLOBULARIA TRICHOSANTHA** (Hair-flowered Globularia).—This species is distinguished by its glaucous foliage and finely-divided petals. It grows from 6 to 8 inches high, and flowers in summer, producing large sky-blue many-flowered heads, very similar in shape to those of *Erigon alpinus*. The flower-stems are herbaceous and leafy, and bear one flower-head each. The whole plant is very smooth and glaucous. Native of Asia Minor. Same positions and culture as for *G. nama*.

**IBERIS JUCUNDA** (Glaucous Iberis).—A little novelty in leaf and flower, from the mountains of Asia Minor; about two and a half inches high. The leaves are ob-lanceolate, about three quarters of an inch long by one-eighth of an inch broad, somewhat glaucous, much attenuated at the base, and with a minute point at the apex. The flowers are in small clusters, and of a pleasing flesh-colour, prettily veined with rose in early summer. This does not as yet appear to possess the rude vigour of our common evergreen Iberises, but it is none the less valuable as a rock-plant for being unlike them, and is fitted for association with a dwarfer and more select set of subjects. Should be planted on warm and sunny parts of the rock-garden, in well-drained sandy loam. Increased by cuttings or seeds. Syn., *Aethionema coridifolium*.

**IRIS IBERICA** (Iberian Iris).—A remarkably striking Iris, reminding one of *I. susiana*, but quite distinct in leaf and flower. Grows from 4 to 16 inches high, and blooms in summer, producing solitary flowers, the external divisions of which are of a dull red, marked with tawny streaks, and an oval, black, purple-edged spot in the middle, while the internal divisions are of a very pale purple, with streaks of a darker hue, and veined and spotted about the base. The leaves are linear, arched, almost curled, and folded lengthwise.

**LEWISIA REDEVIVA** (Bitter Root Plant).—A very singular and ornamental plant, allied to the Mesembryanthemums, resembling a very fleshy-leaved Thrift, and forming rosettes of leaves, each 2 to 3 inches long, on a thick, woody, branching root-stalk. After the leaves attain their full growth in spring or early summer, a profusion of beautiful flowers issues from the rosettes nearly hiding the whole plant. Each blossom is from 3 to 4 inches across, and consists of eight or twelve shaded pink petals, the centre being nearly white and the tips rose-colour, the whole having a very pleasing satiny lustre. The calyx is elegantly veined with red, and is of a consistency like paper. The flowers open only during sunshine. Native of the west parts of N. America, particularly in Washington Territory and Oregon. Should have a warm position in the rock-garden, in dryish soil.

**LITHOSPERMUM CANESCENS** (Hoary Lithospermum).—A species distinguished by its hoary appearance, the whole plant being covered with soft white hairs. Grows from 6 to 15

inches high, and flowers in May, producing large, sessile, salver-shaped flowers, of a deep orange-yellow colour. The leaves are narrowly oblong, obtuse, more or less downy beneath, and roughish above with close adpressed hairs. Northern States of America. Suited for the rock-work or borders, in sandy or peaty loam and grit.

(To be continued.)

**Arundo Donax**.—This plant is usually killed back to the ground with me, and I suppose such is the common experience, but this winter the old stems have survived. Mere accident prevented their removal, and a week or two ago I discovered, to my astonishment, that they were pushing at every joint, from the base upwards within a few inches of the summit. Now I want to know if any of your readers can tell me whether it will not be worth while to allow these old stems to remain, seeing that the development of the laterals must produce a novel effect. Or supposing that it should be deemed desirable to remove them, would it not afford an easy mode of propagating the plant, either by laying the entire stem in the ground or by dividing it into short lengths or single joints. I may perhaps be allowed to add that not only has the *Arundo* preserved its old culms, but even *Aralia papyrifera* has stood unscathed, so far as the stems are concerned; and *Colubonna coccinea*, a somewhat rare Asiatic Labiate, also stands uninjured. On the other hand, notwithstanding their reputed hardy character, *Sparaxis pulcherrima* and *Iris iberica* have suffered greatly, and the former is apparently dead.—EAST ANGLIAN.

**Leptosyne maritima**.—We have received a beautiful bloom of this plant from Mr. Thompson, of Tavern Street, Ipswich, developed of course under glass, on a plant between 3 and 4 feet high, growing in a 48-sized pot. It seems to be a plant of the easiest growth, and promises to bloom in long succession. It will make a noble plant for borders out-of-doors, where its large bright yellow blossoms cannot fail to find admirers, and where it will prove a really splendid addition to our already extensive list of ornamental composites. It is a succulent, smooth-branched plant, from 2 to 3 feet high in suitable soil, with alternate bipinnately divided leaves, with linear entire segments, nearly all borne towards the base of the stems, which, as well as the branches, terminate in a naked peduncle from 6 to 9 inches in length, bearing a very showy flower-head of a golden yellow, 3 inches, or even more, in diameter, the ray-florets being from fifteen to twenty in number. It is a native of the south of California, but seedlings have been raised by Mr. Thompson at a temperature which warrants him in affirming that it will prove of the easiest cultivation as a half-hardy annual. With protection the root is probably perennial. Being of vigorous habit, the seedlings should be pricked off early, and allowed ample pot room prior to turning out. *Agarista calliopsida* is sometimes sold under the present name, but the seeds of the *Leptosyne maritima* are distinguishable at a glance from those of the *Agarista*, by having no pappus, and by being perfectly smooth. The seeds of *Agarista* are densely villous with very long hairs, and have a pappus of two long chaffy scales; they are also smaller than those of the former plant. Seed has been received by Mr. Thompson under the name of *Leptosyne maritima*, variety *gigantea*, and it is possible that a small quantity may be offered under that name, but he has the best authority, that of Dr. Asa Gray, for stating that the supposed variety is, in fact, nothing but the typical *L. maritima*.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Cerithe aspera**.—This, of which I send you some blooms, is with me a lovely spring-flowering biennial. I winter it in a frame.—H. HARPER CREWE.

**Helleborus argutifolius**.—This is the finest of all the Hellebores, as regards foliage. It is now in flower at Bitton, forming a mass between 3 and 4 feet high. After flowering it is cut down. During the summer it forms a noble tuft of fine leaves, and is very effective indeed in this form. It is said to be a variety of *H. lividus*.

**New Zealand Flax** (see p. 257).—I was enquiring the other day, on being shown a damask table-cloth, made from the fibre of this flax, whether it would answer to grow the plant in England, and I was informed that, while the fibre from the plant grown in New Zealand would cut your hand before you could break it, that from plants grown in Jersey, where they seemed to flourish, was rotten and worthless. It requires five tons weight of leaves to produce one ton of fibre.—W. T. P.

**Drooping Plants for Rockwork**.—We have a newly-made pond in the centre of our carriage drive near the house. Can you recommend me any plants that will grow quickly over its rockwork edges, and also over a modern "Druid's seat" that has been erected on a cliff commanding a splendid view of the lovely surrounding country?—B. F., near Shanklin, Isle of Wight. [The following are the best plants for your purpose, viz.: Various kinds of *Aubrietia* and *Arabis*, *Coronilla varia*, *Dryas octopetala*, *Geunia prostrata*, perennial kinds of *Iberis*, *Lithospermum prostratum*, common Moneywort, *Saxif. reticulata*, *Saponaria ocyminoides*, some of the mossy kinds of *Saxifrage*, *Thymus lanuginosus* and *Vincas* in variety.]

## THE LIBRARY.

## THE TROPICAL WORLD.\*

This is one of the most readable books that have fallen into our hands for some time, and we do not know any single volume that affords so good and comprehensive an account of the inhabitants and the leading natural features of the torrid zone. The various tribes of men, the animals, plants, insects, &c., are all successively described in the most pleasing manner, and in each department the illustrations are numerous and well chosen. Of the *matériel* of the volume it is sufficient to say that Messrs. Longmans & Co. are the publishers, and that in its paper, typography, &c., it well sustains the reputation of that eminent firm. We should find it difficult to select a more interesting and valuable book-present for our younger friends, while we are convinced that not a few of the older ones would be highly gratified, as we ourselves have been, by its perusal. We append two short extracts, with their appropriate illustrations:—

## THE BOTTLE TREE.

The trunk of several tropical trees offers the remarkable peculiarity of bulging out in the middle like a barrel. In the Brazilian forests, the Pao Barrigudo (*Chorisia ventricosa*) arrests the attention of every traveller by its odd ventricose shape, nearly half as broad in the centre as long, and gradually tapering towards the bottom and the top, whence spring a few thin and scanty branches. It is only by seeing great numbers of these trees, all with their character more or less palpable, that one can believe it is not an accidental circumstance in the individual tree, instead of being truly characteristic of the species.

The Delabechea, or Bottle tree, discovered by Mr. Mitchell in tropical Australia, has the same lumpish mode of growth. Its wood is of so loose a texture that, when boiling water is poured over its shavings, a clear jelly is formed, and becomes a thick viscid mass.

## THE MANGROVES.

The roots of the Mangroves, which in the tropical zone are found fringing the shores of the sea, or the mouths of rivers, wherever the reflux of the tide exposes a broad belt of alluvial soil, are admirably adapted for securing a footing on the unstable brink of the ocean. The growth of these sea-water-loving trees (*Rhizophora gymnorhiza*, *R. Mangle*) is equally peculiar and picturesque. The seeds germinate on the branches, and, increasing to a considerable length, finally fall down into the mud, where they stick, with their sharp point buried, and soon take root. As the young Mangrove grows upwards, pendulous roots issue from the trunk and low branches, and ultimately strike into the muddy ground, where they increase to the thickness of a man's leg; so that the whole has the appearance of a complicated series of loops and arches, from 5 to 10 feet high, supporting the body of the tree like so many artificial stakes. It may easily be imagined what dense and inextricable thickets, what incomparable breakwaters, plants like these—through whose mazes even the light-footed Indian can only penetrate by stepping from root to root—are capable of forming. Their influence in promoting the growth of land is very great, and in course of time they advance over the shallow borders of the ocean. Their matted roots stem the flow of the waters, and, retaining the earthy particles that sink to the bottom between them, gradually raise the level of the soil. As the new formation progresses, thousands of seeds begin to germinate upon its muddy foundation, thousands of cables descend, still further to consolidate it; and thus foot by foot, year after year, the Man-

groves extend their empire and encroach upon the maritime domains. The enormous deltas of many tropical rivers partly owe their immense development to the unceasing expansion of these littoral woods; and their influence should by no means be overlooked by the geologist when describing the ancient and eternal strife between land and ocean. When the waters retire from under the tangled arcades of the Mangroves, the black mud, which forms the congenial soil of these plants, appears teeming with a boundless variety of life. It absolutely swarms with the lower marine animals, with myriads of holothurians, annelides, sea-urchins, entomostraca, pagnri, and crabs, whose often brilliantly-coloured carapaces form a strong contrast to the black ooze in which they are seen to crawl about. Life elings even to the roots and branches bathed by the rising floods; for they are found covered with mussels, barnacles, and oysters, which thus have the appearance of growing upon trees, and pass one-half of their existence under water, the other in the sultry atmosphere of a tropical shore. (See p. 319.)

## PHEASANTS FOR THE COVERT AND THE AVIARY.\*

This is the first number of an excellent monograph from the able pen of Mr. Tegetmeier, distinguished, like the other works of that gentleman, by showing a full knowledge of the

subject and the ability to discuss it which springs from a long and varied experience. Its aim will be best expressed in the following extract from the preface: "To indicate and illustrate the various species: to give, as far as is known, their natural history; to describe the best methods of rearing them in preserves and enclosed pheasantries; to enter into the numerous little details respecting their food, management, protection, diseases, &c., is the object at which I have aimed in the preparation of the following work. In the next chapter I shall treat of the natural history of the pheasants generally—their food, habits, nesting, &c., as far as may be considered desirable in a work of this kind. Then will follow the consideration of their management in preserves, the details of the different methods of feeding the birds, their protection from their numerous enemies, the formation of coverts, &c. This will be succeeded by an account of their

treatment in enclosed pheasantries, the hatching of the eggs, rearing and feeding the young birds, and the prevention and cure of their diseases. A detailed description of all the different species adapted for turning out, and of the various hybrids and crosses between them, will follow, and the work will conclude with an account of the allied ornamental species, such as the Gold, Silver, and Amherst pheasants, and the best methods of their management in aviaries." On the value of such a repertory of instructive information to the country gentleman we need not here enlarge, and we shall only add that the work will be completed in four parts, that it is beautifully printed in imperial quarto, and that the illustrations in the first part, now before us, are simply exquisite; so much so that, apart from the practical worth of its contents, the volume will form a charming ornament for the drawing-room table.

"THE COUNTRY: a Journal of Rural Pursuits," is the name of a new journal which is about to be added to the list of weekly newspapers. It is to treat upon everything connected with sport, natural science, and all else belonging to country life.

## THE FRUIT GARDEN.

### PEAR CULTURE.

BY JOHN SCOTT.

No fruit cultivated in our gardens and orchards has made more progress than the Pear; nor are there any other sorts of fruits that can vie with it in beauty, flavour, or usefulness. From the middle of June in one year to May in the next, this fine fruit can be enjoyed either in the dessert or cooked in various ways. In France and Belgium Pears are dried in ovens, and during the spring and summer months form an important article of food made into jelly, for the making of which some of the kinds are unsurpassed by any other fruit. The finer kinds of dessert Pears are generally of a soft, melting, rich, sugary, and aromatic character, such as *Marechal de la Cour*, grown upon a Quince stock. In some counties, especially Herefordshire and some parts of Gloucestershire, the Pear is largely grown for the purpose of making perry; but Britain falls far behind France in perry making. In this country we only cultivate a few sorts for that purpose, such as the *Barland*, *Holmore*, *Huffcap*, *Longland*, *Oldfield*, the *Teinton Squash*, and a few others; but in France they cultivate, in the various departments, such as *Artois*, *Auxerrois*, *Beauce*, *Beauvois*, *Berry*, and forty to fifty other places, a great number of kinds, amounting to over 1,500, and probably not less than 2,000 sorts of perry Pears. The Pears that are grown in each department of France are generally named and well known to the various cultivators, and although there may be many kinds in the various orchards that are only synonyms of those in other orchards, yet there are a great many of well-defined and well-known forms, spread throughout the country, each locality cultivating its own favourite kinds. But, like the cider Apples of Britain, the perry Pears of France require to be gathered together in one place under the management of some individual, imbued with a love of research, order, and classification, who would arrange and determine the various sorts, so that something like a reliable authority might be established.

As regards culture of Pears worked upon the Quince stock, I have above 1,600 sorts, most of which grow freely and bear abundantly. There are many other sorts that will grow upon it; but they make so little wood, and bear so much, that they perish in seven or eight years.

Merlet, writing in 1667, recommends the Portugal Quince as a stock, as it is stronger and more favourable for working Pears upon than any other variety. Its juice is more abundant, and it produces larger and finer flavoured fruit than any other sort. It has, too, this advantage, that it swells equally fast with the graft, which none of the other sorts do. Le Gendre, about the same time, referring to the grafting of the Pear upon the Quince, in his work "*Le Maniere de Cultiver les Arbres Fruitiers*," says:—"I have been much aided by the invention of grafting the Pear upon the Quince;" and, further, that he was one of the first who helped to spread the system. Pears grafted on the Quince should be planted so deep that the junction of the graft and stock may be about two or three inches under the ground. This will cause the trees to grow more freely, and live longer than they otherwise would do; and, in cold winters, it will protect the stock, as it is liable to be injured by severe frost. It has been said by some that the Pear graft would send out roots at its junction with the Quince and thus render the Quince useless. I have, however, thousands of Pears worked upon the Quince, and all their junctions buried about two inches under the ground, many having been so nearly twenty years; yet I have never found one to root above the junction, and I think I am safe in saying that not one in a hundred does so. Pears budded or grafted on the Quince, as well as upon the Pear stock, differ very much in their constitution and in the strength of their wood, some growing strongly and freely, whilst others make short and fertile branches. These last do not require root-pruning; but the former will require to be periodically lifted and replanted, some in two years, some in three; but others will require four or five years before they want moving or root-pruning. Where the operation is left beyond two years, however, care must be taken that the trees do not receive too great a check. To prevent this, it will be best only to cut round half the roots one

year, and the other half the next, making half a circle round the tree each year, about twelve or eighteen inches off, as the strength of the branches may indicate; the second half may require to be left uncut for two or three years, according to circumstances. Pears on Quinces make fine dwarf espaliers, also very nice trees for low walls, on which they can be either trained fan-shaped, horizontally, upright, or *en cordon*, in which way a great number of sorts can be grown in little room. In exposed places these low-growing trees are very valuable, as, being of low growth, they do not suffer from storms so much as the larger-growing trees. A mode of culture well adapted to all hardy fruit trees in exposed situations is the low bush form. In this state Pear trees can be kept dwarf and handsome objects by cultivating them something in the form of Gooseberry or Currant bushes, keeping them nicely regulated and thin. Apples, Cherries, Pears, and Plums are well adapted for this mode of culture, and generally bear abundantly, especially if kept well root-pruned. They may also be planted in squares six feet apart; this will afford an easy means of protecting them, either by means of nets, tiffany, or canvas. It has been recommended by a writer on fruit to frequently summer-prune these bush Pears; but root-pruning will effect the object much better, and over-pinching soon causes trees to decay.

The cultivation and formation of pyramidal Pear trees, whether upon the Pear stock or upon the Quince, is fraught with so many advantages, that I must here give a short description of my mode of cultivating them. In the years 1836-7-8 I studied horticulture in the "*Jardin Fruitier*," at Paris, under M. Dalbret, who is favourably known by his work on the pruning of fruit trees. His duty it was most especially to attend to the cultivation and introduction of fruits into the establishment. Under his management, directed by the scientific skill of M. André Thoinin, were formed those beautiful, but at that time barren, pyramids, of which we have heard so much during these last twenty years. I recollect how it used to grieve me to see so much labour thrown away in forming such beautiful cones, apparently to no purpose; for during the time I resided in the garden, I do not recollect to have seen a fruit upon any of them. How I longed to take a spade and curtail their roots, so that, instead of carrying off annually loads of spray, my friend Dalbert might be able to carry off bushels of fruit. I have been an ardent pomologist all my life, and I have been a root-pruner for more than forty years. How I came to a knowledge of such a beneficial system was, when studying under the well-known author of the "*Book of the Garden*," then at Claremont, who was in the habit at that time (1830 and onward) of root-pruning the old Pear trees on the walls; and seeing the fine crops that the trees so operated upon bore, from that time to this I have followed the plan of root-pruning, of which I there learned the benefit. I also acquired much information about fruit trees and other kindred subjects, amongst them root-pruning to cause fertility, and certain it is that this in the present day has become more essential than even branch-pruning. The old adage that "*He who plants Pears, plants for his heirs*," is now no longer admissible, as most sorts, even the most untractable, may be rendered fruitful from the time they are four or five years old.

To form handsome pyramids, it is necessary to commence with the tree at the age of one year, although to parties requiring these it is generally better to purchase young ones four or five years old, which have gone through a regular system of training in the nursery, as time will be saved, and a crop of fruit may generally be obtained the second year after planting trees of the age recommended. However, let me give the procedure from the commencement. Having obtained some nice straight young trees, plant them where they are to remain, in October. Let them stand until the spring following before they are cut back, so that they may take root, and be able to push their branches the following summer. In February or March let all be topped back to about 15 or 18 inches. It is always best to cut well in the first year, as the future trees depend upon this; if left too long you will have too high a stem, and the beauty of the plant will be marred, at least for a few years, although ultimately the branches will come down and cover the stem. But for those

who wish to grow other crops, near or under their pyramids, a longer stem will be preferable, say about 2½ feet—my largest pyramids are 20 feet high, and the branches touch the ground; I have now pruned them up to 2½ feet, the branches will again come down, but be freer from the earth being washed upon the fruit by heavy rains. One year from the time of planting, the tree will have made four or five shoots, the centre of which is to form the leader; the others should be shortened back in February to 9 or 12 inches. You have then your tree ready for its third year's growth, which will be considerable. If the soil is good, during the third summer it will probably make twelve to fifteen shoots of considerable length and strength; and as the tree now begins to assume a good size, it must be the aim of the cultivator to throw it into a bearing state as soon as possible. Instead, therefore, of allowing the shoots to form their whole growth, they ought to be pinched back when they have reached the length of 15 or 18 inches. This will be in July, when 4 to 6 inches should be pinched off the end of all the shoots, except the leader, which should be encouraged to grow straight; the side shoots being pinched will mature their lower buds, and these will swell so as in the next season to become, in many instances, fruit spurs. The leaders are to be shortened to from 18 inches to 2 feet in the spring, when a little thinning and regulating of the branches will have to be done. The fourth year should be a continuation of the procedure of the third, and so on to the fifth, when the trees will have become large enough to have their roots operated upon. If there is no fruit on the trees, this should be done in the end of July or beginning of August, by cutting a trench all round about one foot from the stem, as a centre, digging well down and cutting every root off that protrudes 15 inches beyond the centre, going well in below, and making the spade meet all round under the tree. As soon as this is done, fill in the poorest of the earth, ramming it quite hard around the bottom roots, gently raising the ball a few inches. Then, 6 inches from the surface, dig in some good half-decayed stable manure, placing it as near the surface as possible, to encourage the roots upwards. By doing this a mat of roots will soon be formed, within reach of sun and air, whilst the lower roots will be less and less developed, thus cutting off the supply of cold, crude aliment from below, the source of unfruitfulness in most trees. I have recommended no fruit-pruning in a general way to take place before the trees have got to a considerable size, as time would be lost by operating sooner; and as they receive a considerable check the first season in which they are root-pruned, it generally results in a disposition to form fruit buds, and the necessity for after root-pruning is much lessened, as the trees will then begin to bear, which of itself will keep them from forming great quantities of wood. However, as some seasons prove unfruitful, an advance in wood formation will take place, when, early in the autumn, the spade must again be freely made use of. If attention be paid to check over-luxuriant growth, Pear trees will, in a few years, form such fine matted balls of roots that they might with safety be removed, with all their fruit on them, to a considerable distance. The great things to be attended to are root-pruning, shortening overgrown branches in the end of July, and a systematic regulation of them every winter or spring.

(To be continued.)

GLASS BACK WALLS FOR EARLY FRUIT HOUSES.

EVERY gardener knows that after the beginning of April his steep pitched early Peach-houses and vineries lose the sun's rays early in the afternoon, and that they do not receive them again until late the following morning. For hours every day the morning and evening sun beats upon the north side of the back wall of his hothouses, while his early Peach trees and Vines are cast into the shade. He has to light his fires early in the afternoon, in order to meet the quick fall of the thermometer, which he knows will take place as soon as the sun is "off his houses." And in severe weather he must keep up the heat till our great luminary again shows his face on the south side of the wall the following day. For the last ten days the sun has been shining upon the north side of our early Peach house back wall, for three hours, or more, every day, and with a force sufficient in the evening to keep up the temperature of the house till seven o'clock at least, without extra assistance from fire-heat, had the back wall been of glass instead of being a 20-inch brick wall; but the weather, though bright, has been keen and cold, and fires have had to be lighted every day by two o'clock, for the sun goes over the wall shortly after four o'clock p.m., and so coal is wasted to a considerable amount, and time and the energetic influence of the sun are lost. Now, I see no obstacle whatever to a strong glass screen, say of thirty ounce glass, being made to take the place of the brickwork in early houses. We could thus secure the advantages of a span-roofed and lean-to house at the same time, for the trees would have sunlight on all sides, and for a much longer time every day than at present, while the evils to which trees on back walls are subjected, as our houses are now constructed, would to a great extent disappear, for they would have a blaze of light on both sides at different times during the day. I am not aware that any such structures have yet been recommended, but that they would answer I have no doubt.

We have here a glass case, 9 feet wide, with a horizontal ridge-and-furrow roof, and upright fronts. The Peach trees are trained up the trellis in front, and horizontally under the ridges of the top. In a division devoted to Grapes, the Vines are trained in the same way, and the noticeable feature is, that every year we gather Peaches and cut Grapes from the branches under the ridges, ten days or a fortnight earlier than we can from the trees on the front trellis; farther, the fruit from under the ridges is always the finest, and the wood there is stronger and better ripened than it is elsewhere, and this is entirely due to the abundance of light and long-continued sunshine which the top branches receive, for the ridges stand above the coping of the back wall, and get the sun early and late, while the front trees get it for a part of the day only. The difference may be noticed at any time by the most casual observer, and has often enough been remarked upon by gardeners who have visited the gardens here. I think that the utilisation of the sun's heat ought to be studied to better purpose than it often is in the construction of our hothouses, and also in our daily practice, if for no other reason than for the saving in coal which in that way might be effected.

Wortley.

J. SIMPSON.

Keeping late Grapes in Bottles.—I have practised this plan of keeping Grapes for some time, and I find it to answer per-

The Mangrove. (See p. 317.)

fectly, provided the fruit is perfectly ripe when cut; but, if unripe it will not keep. I am pleased to see that Mr. Tillery still thinks well of the bottling system. Mr. Kettles, the gardener at Archerfield, speaks favourably of my "Grape-rails," from which he supplied his employer's table the other day with fruit put on them about the middle of last September; yet, he says, "the berries were plump, high coloured, and very fine." On the 12th of this month I placed on my employer's dinner-table Muscats and Lady Downes seedling Grapes of 1872, cut six months from the Vines, also black Hamburgs of 1873. Of the Lady Downes I send you a sample bunch, cut from the Vine six months ago, in order that you may test its quality. The bottles which I use only require to be filled with water once in twelve months, and my improved Grape-rails are now all made self-supporting. The Vines from which I cut the ripe Hamburgs were only fourteen months old from the day in which the eyes were put in to start, and I may add that I have managed to fruit Vines in this space of time every season for these last ten years.—RICHARD NISBET, *Aswarby Park Garden*. [The bunch of Lady Downes sent was in every way excellent, the berries being large and plump, and the flavour all that could possibly be desired.]

**Keeping Grapes on the Vines.**—In reference to the question as to whether late Grapes, when allowed to hang on the Vines three or four months after they are ripe and the leaves have fallen, have any tendency to exhaust or weaken them or not, I suppose all will admit that there is a constant evaporation going on from ripe Grapes, varying, of course, according to temperature. To prove this, it is only necessary to sever a bunch from the Vine and suspend it in the same house, and to mark the difference in condition which two or three days will make. The footstalks will become flaccid, and the berries will lose their plumpness and freshness. But if the same bunch is hung up in a dry room that is not much influenced by the external temperature, the evaporation is much less, and if the room is darkened it will be reduced to a minimum. Where, therefore, does the supply come from to make good the loss caused by evaporation, if not from the Vine? As far as my observation goes, after the fall of the leaf growth recommences. Vines, unlike many deciduous trees, do not extend their roots in winter. I have been examining and testing this subject for years, and this has been the case invariably, both with bottom heat and without it. Until the buds break and commence unfolding their leaves, there is no root extension. Therefore, if a heavy crop of Grapes hang long after the leaves have fallen and root action ceases, the loss by means of evaporation must be supplied from the stored-up sap. This, at least, is my view of the case; and the conclusion I draw, and that which I think is generally acted on by practical men, is this: When from necessity the Grapes have to hang on the Vines a long time after they are ripe, they must be cropped well within their strength; or, in other words, a less crop must be taken than if it could be cleared off within a reasonable time. The fact that "J. S. W.'s" Vines have borne good crops for twelve or more years, and that they have retained their vigour unimpaired, does not prove that Grapes hanging on Vines long after they are ripe do not exhaust them. Cropping Vines, or indeed any other fruit tree, is entirely a question of degree. What one calls a heavy crop, another thinks only a moderate one; but what all should aim at is to crop according to strength. We may plant a house of young Vines, and treat all alike as to soil, &c., but some will probably have much more strength and vigour than others. I believe in cases where there is any marked difference in the strength of Vines in a house, it is good policy to allow the strongest to extend itself laterally, and so gradually remove the others. I can only say, in several instances where I have seen this acted upon the result has been highly satisfactory. After a wet cloudy season like last summer, Vines that were started late might not perfectly finish their fruit. Although fairly coloured, they might still be deficient in saccharine matter, and therefore would not keep well, either on the Vines or in bottles. A good many years ago, when the Black Hamburg in many gardens (so far, at least, as black Grapes were concerned) furnished both the early and late supplies, it was the custom in some places to retard its breaking as long as possible, if the object was late Grapes, in order to prolong its rest; but thick-skinned kinds, like the Alicante, Barbarossa, and Lady Downes, require all the time there is in an average English summer to mature their fruit before the short dark days set in. I believe the sooner all late Vines are pruned after January the better it is for them; and the longer their period of rest the stronger will they break, and its influence will be felt in swelling off and finishing their fruit.—E. HODDAY.

**Col. Cheney Strawberry.**—A correspondent of the *Rural Home* says if he were to have but one variety, this would be his choice. He finds it as hardy and productive as the Wilson, while it is much superior to that variety in size and flavour, an opinion in which the editor of the *American Agriculturist* agrees.

### VEGETATION IN THE PHILIPPINE ISLANDS.

THE soil of these islands is wonderfully fertile, and the produce enormous, especially that of sugar, coffee, cocoa, rice, cotton, hemp, indigo, and tobacco. They furnish a wood used for dyeing purposes, which is largely exported. It is called Sappan wood, and is the produce of *Cæsalpinia Sappan*, *C. pulcherrima*, and various other species; from the island of Koilo a substance resembling gutta percha has been obtained from a tree which the natives call "Nato." Most of the sugar and coffee from the Philippine Islands comes to England, whilst their hemp finds its way into the hands of the Americans, and the majority of their tobacco exports go to Spain. Manila hemp, called by the natives "Abaca," is the produce of *Musa textilis*; it is both fine and strong; the natives manufacture many things from it, such as table-mats and ornamental fancy baskets. The island of Luzon abounds with choice plants, but its laws strictly prohibit foreigners from going into the interior, and thus we are left in almost total ignorance of its flora. The interior of the country is intersected by ranges of hills, forests, rivers, and lakes. Around the lakes, as seen in our illustration, tropical vegetation, consisting of Tree Ferns, Bamboos, and large species of Ficus, luxuriates. In such spots may be found Tree Ferns and Filmy Ferns, choice Orchids and magnificent Aroids. The Fern flora is indeed most extensive, and such Orchids as have hitherto been obtained from the Philippines go to prove that glorious new species are in waiting for any adventurous collector who can penetrate to the interior of the different islands, and who can happily return safely with his treasures. Amongst Orchids known to exist there, a few of the most noted are—*Vanda Batemani*, *Saccolabium violaceum*, *Dendrobium onosmum*, *D. superbum giganteum*, *D. taurinum*, *D. tortile*, *Acrides quinquevulnerum*, *Cypripedium laevigatum*, *Dendrobium filiforme* and *glumaceum*, besides various beautiful species of *Cirrhopetalum*, *Cleisostoma*, and *Phalenopsis*, of which we have already received from these islands *P. Schilleriana*, *rosea*, *amabilis*, *Luddemania*, *grandiflora*, *intermedia*, and *Portei*. What a galaxy of beauty do such names suggest! Turning from Orchids to Ferns, there are immense numbers of real gems. Cumming brought home dried specimens, the living representatives of which we should like to see in our Ferneries. Of these, a few of the most desirable were one *Photinopteris Horsfieldii*, a singular and beautiful plant, with Laurel-like leaves of the most brilliant, shining green; many fine species of *Trichomanes* and *Hymenophyllum*, *Aglaomorpha Meyeriana*, *Dryostachyum splendens*, *Lecanopteris carnosula*, *Tenitis blechnoides*, *Dipteris Horsfieldii*, *Gleichenia excelsa*, *bifurcata*, and others, *Neottopteris musæfolia*, *Kaulfussia aesculifolia*, and many other genera. Of Philippine Island Tree Ferns we have one species in cultivation—viz., *Alsophila glauca*; there are, however, some seven or eight other kinds known to exist which have not reached us, some of them finer than anything of the kind we yet have; in fact, nearly three hundred distinct species of Ferns have been discovered in these islands, the majority of which are peculiar to them; while, to show how rich in Ferns the Island of Luzon must be, I may add that upwards of two hundred out of the number of kinds discovered belong to that place. Of the general flora, however, we know little. Of forest trees, various species of the following genera are known to inhabit these islands—viz., *Diospyros*, *Dipterocarpus*, *Ficus*, *Cedrela*, and *Artocarpus*. The Talipot Palm (*Corypha*), also abounds, as do also *Caryota Cumingii*, and many species of *Calamus*, which grow in some instances upwards of 100 feet in length; of these the most noteworthy are *mollis*, *nsitatus*, *maximus*, and *gracilis*. Of shrubs and underwood may be named *Ixoras*, *Curcumas*, *Alocasias*, and numerous Aroids, *Crinums*, Pitcher plants, and Bromeliads. Of this latter order *Bromelia Pinguin* produces a splendid fibre called Pina muslin, very soft and delicate in texture. From this, too, are made the cigar-cases which are so much prized in this country. In the West Indies, the cooling juice of the fruit is highly prized in cases of fever, &c. Many of the Bromeliads supply valuable fibre for textile purposes, and which might also be employed in the manufacture of paper. Several species are cultivated for the sake of their flowers. Pandanus or Screw-Pines also abound in these islands, *P. ornatus*, *P. Blancoi*, and *P. Porteanus* having already been introduced. G.

VEGETATION IN THE PHILIPPINE ISLANDS.

## THE ARBORETUM.

### THE FIRST ROBINIA PSEUD-ACACIA INTRODUCED INTO EUROPE.

To a gardener visiting Paris, one of the most interesting sights is all that now remains of a somewhat remarkable tree which has stood for the last 237 years in the gardens of the Muséum. The seed from which it sprang was received amongst others from North America in the year 1601, by Jean Robin, Professor of Botany at the Jardin des Plantes, and, thirty-five years later, the subject of our notice was planted in the gardens of the Muséum by Vespasien Robin, so that it is now probably 272 years old. The top of the tree, having gradually decayed, was cut off many years since, and the stump of a trunk which remains is about 9 feet high, and 3 feet 3 inches in diameter at the base. It bears at its summit the stumps of three of the principal branches, to which the two living branches are secured and supported by bands of iron. The stump of the trunk is very much decayed and abounds in splits and crevices, which, with a view to its preservation, have been carefully filled up with plaster. The branches which still continue alive, however, exhibit a considerable amount of vigour, which promises a prolongation of existence for many years to come. Near the top of the stump may be seen a label bearing the following inscription:—

ROBINIA PSEUDO-ACACIA, L.  
*Acacia Virginensis spinosa*, Roy.  
Amérique septentrionale  
Introduit en France par Jean Robin  
en 1601,  
Planté par Vespasien Robin,  
en 1636.

This venerable tree is considered to be the parent of all the varieties of Robinia which are now so extensively spread over the continent.

**Metrosideros florida as a Hardy Shrub.**—On a nice snny border I planted out an old plant of this, which had grown too large for the conservatory. Not liking to cut it in, I thought I would try its hardiness out-of-doors. That was in the spring of 1869. As summer drew on, it commenced growing rapidly, and was soon covered with its singular bottle-brush-like flowers, which were much finer and were produced with greater freedom than I had ever seen them whilst the plant was growing under glass. Winter came, but it was prepared for hard weather, for I found that it had well matured its growth, and it withstood the winter without the least protection. It has continued making a good growth every summer, and has also continued blooming very freely, and that on a very elevated spot in Derbyshire. I may add that there was no preparation made as to soil; it was merely planted in the ordinary soil, which was very shallow, upon rough grit stone rock. It has occurred to me that it might make a very beautiful addition to our shrubberies, for when in bloom it was the admiration of all who saw it. Not very many years ago we used to see the *Escallonia rubra* in our green-houses. Now it covers many an outside wall, and many other plants might be named which, could our good old departed friends of the craft see, would cause them much astonishment.—C. COOMBS, *Tabley, Kantsford.*

**The Douglas Oak.**—Can you kindly give me any information respecting this Oak? I see it named in catalogues; but have never had an opportunity of personally inspecting it.—*QUERUS.* [Mr. Meehan states, in "Proceedings of the Academy of Natural Sciences of Philadelphia," that "he had journeyed last summer several hundred miles through the Rocky Mountains of Colorado, and had noted remarkable variations in the only species of Oak in that region—*Quercus Douglasii* or *Q. Neo-mexicana* of some authors. The first plants he found of this occupied large clumps in flat open spaces, and grew only about 3 feet high. He felt sure he had several species, and collected specimens accordingly. One form had the leaves so much like the *Q. Cerris* of Europe, that branches of the two mixed together could scarcely be separated; others closely resembled the European *Q. robur*; and again some came near *Q. alba*. It was, therefore, only after many successive days of acquaintance with it, during which it had ranged from a low bush to a small tree, from leaves deeply lobed to leaves almost entire, from leaves of a deep, shining green to leaves of a glaucous gray, trees with fruit pretty well matured, to others only just commencing to set their fruit—from long to short pedunculated, elongated to sub-rounded fruit, and so on through other changes, that he was forced to the conclusion that he had but one species to deal with, viz., *Q. Douglasii*. It may, therefore, be set down as a very variable species.]

**The Movement of the Sap.**—Your correspondent, Mr. J. Brennan (see p. 278), has mistaken my opinion when he writes—"The correspondence which you have hitherto published on this subject tends to show that sap does not descend." I said that it descended and was absorbed, but did not re-ascend or circulate as does animal blood. Sap is nutriment undigested, cambium is the fat secretion of the plant. The Geranium cutting must contain succulent albumum, or sap-wood and cambium; it must not be dry, dead duramen; it requires the artificial spring or summer heat, which causes chemical action, dissolving the starch and stored-up nutriment, so that the vital action of growth by cell-division may commence, just as the camel subsists on its own fat. The laws of osmosis would prevent the re-ascend of the dense, concentrated, de-oxidised, sap. The un-elaborated sap ascends through the albumum, is elaborated, and descends through the cambium, the increase of which it causes. From the cambium originate both bark and wood.—LECTOR.

**Cryptomeria pungens rubiginosa.**—The form of *Cryptomeria* which has been named *C. pungens* is considered to be a variety of *C. japonica* with larger, more distinct, and more pointed leaves, from which last-named characteristic it derives its specific name. The variety *C. p. rubiginosa* first made its appearance among some seedlings of *C. pungens*, from which it differs by a single remarkable peculiarity, namely, that in the month of August all the leaves and branches assume a coppery or tawny-red colour, which they retain until the following March or April, when they revert to their original green; so that for at least seven months the tree presents the aspect of some of the New Zealand Conifers, such as *Dacrydium* and *Podocarpus*, and forms a very striking contrast with other Conifers whose leaves continue evergreen. *C. p. rubiginosa* does well in any soil that Conifers will grow in, and is easily multiplied from cuttings, which it will be advisable to take from strong shoots or branches, if strong and vigorous trees are desired.

**Planting Poplars.**—I was engaged this spring in thinning a plantation in Dumfriesshire, about 500 feet above sea level, planted forty years ago. The wood was well grown and very marketable, the Spruce averaging about 8 feet cubic, and the Larch about 9 feet. For the former I got 9d. per foot, and for the latter 1s. 3d., delivered at the nearest railway station. In one of the most exposed parts of the plantation, where the Fir trees were considerably under these averages, a row of white Poplars had been planted along a drain conveying the water from a neighbouring field. I cut four of these, rather under the average, and they measured 36 feet cubic each. I sold them at 1s. 4d. per foot, or rather more, as I got £10 for the four from the same man to whom the other wood was sold. I have for some years been sensible of the profit of planting the larger kinds of Poplars, for the wood of which there is now so much demand for railway breaks, &c., and find the Abele Poplar grow rapidly in sheltered situations, but the black Italian does better where the situation is more exposed. A damp clay or near the side of a runnel does well for them; and in all cases their light fibrous roots require the soil to be well loosened when they are planted.—*J. H. J. S., in The Field.*

### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Hydrangea paniculata grandiflora.**—Take it all in all, this is the finest shrub we have. THE GARDEN says it grows from 20 to over 30 inches high. Ours last year was about 5 feet high, and it is a young plant yet.—*American Agriculturist.*

**Pinus Sinclairii.**—I am invited to see a fruiting specimen of this Pine. What is it? Where does it come from? When was it introduced? and how may I know it to be what it professes to be? I fail to find it referred to in any books or lists of conifers.—*W. F. P.* [The *Pinus Sinclairii* of Sir William Hooker is the same as *P. Benthamiana*, and was introduced by Hartwig from California in 1848.]

**Prunus triloba.**—This, either against walls or in the open ground, is one of our loveliest shrubs, the delicate pink of its double, large, and densely-produced blossoms being quite distinct from anything else. By growing a few plants of it against a sunny wall, and some in the open ground, an agreeable succession of bloom is obtained. Being of good free habit it is well suited for isolating or grouping with other good shrubs on the Grass.—*R.*

**Durability of Chestnut Timber.**—The roof of Westminster Abbey, long supposed to be of Oak, when examined some time ago as to its soundness, and found to be perfect, was at the same time discovered to be of Chestnut. It has stood for eight centuries already, which would go to show that Chestnut timber would at least serve any such purpose now very excellently. Another very valuable quality it possesses is, that its growth is many times more rapid than that of Oak.

**Old Oak Trees.**—In THE GARDEN (see p. 253), is a short account of the remarkable Oak felled in 1810, near Newport, in Monmouthshire. It may interest some of your readers to know that in *Time's Telescope* for 1816, it is stated that the quantity of its bark amounted to 65 cwt., and that it contained 45 load and 26 feet of timber. The men engaged in squaring it for ship timber were at work three weeks and four days, and one pair of sawyers were employed for above five months upon it. The whole produce of the tree, when brought to market, was valued at rather less than £600, and the labour involved in converting it into timber exceeded £82.—*R. G. BAKER, Ivy Cottage, Faltham.*

## THE GARDEN IN THE HOUSE.

## BUTTON-HOLE FLOWERS.

FERNS used for button-hole, or indeed for any kind of bouquets, should be cut off plants that have been grown in a cool house, or that have at all events been well hardened off, or otherwise, though they may look fresh and nice when cut, they shrivel up in a few hours, when of course their beauty is gone. In the case of Maiden-hair it is a good plan to cut off the very young points, as, with the exception of these, the other parts of the frond keep well. Another point that should be remembered is always to keep the stems of the button-holes as thin as possible, in order that they may easily pass through the coat, and nicely fit the little glass water-tubes which are now so much worn, and which keep both Ferns and flowers fresh so much longer than they otherwise would be. After the bouquets are made, many place their stems in water, to keep

A Coat Flower (Dendrobium and Maiden-hair).

them fresh; this I do not think a good plan, as, though the stems may be in the water, the Ferns are exposed to the air, and, thus circumstanced, they will not keep nearly so long fresh as if they were shut up in some air-tight box or drawer. Dealers in bouquets have numbers of drawers lined with zinc in which they keep their flowers, mounted or otherwise, but though those who have shops must have such appliances as these, it is not to be expected that amateurs will be furnished with them. If I want to keep a button-hole flower from one day to another I place it in a common little box made either of wood or cardboard, over the bottom of which is laid some wet Moss of the kind one gets in bundles at the flower shops or finds in woods or on banks. I place the back of the bouquet next the Moss and cover the stem over with some more wet Moss. I then sprinkle the flowers and Ferns well with water and shut down the lid, which is as air-tight as possible, and, treated thus, flowers and Ferns will keep fresh for days. If I want to send a bouquet by post, I put Moss enough in the box to raise the bouquet when laid in it nearly level with the lid when shut down, and across the face of the flowers I lay a piece of cotton wool, which keeps them from rubbing against the lid. The illustration given above represents a flower of *Dendrobium nobile*, backed with a spray of Maiden-hair Fern.

A. H.

## NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

**Aponogeton distachyon.**—This grows freely indoors in a bell-glass. It may now be seen flowering freely in the Me-enbryanthemum house at Kew, which it fills with its fragrance. This plant is growing in a bell-glass about 15 inches in diameter, and has been blooming for the past three months.

**Everlastings.**—Nearly seven years ago I tried to group some of these gracefully under a glass-case, covering a little silver epergne. I only used two kinds, the little Yellow Everlasting which is used for the immortelles, and which thrives in the sandy loam of my garden, and that elegant Grass, *Bromus briziformis*, which I hope I may venture to call an "everlasting." Both these things look as fresh and pretty now as they did when I placed them under the glass. A few of the Grass flowers have fallen, no doubt from the glass being frequently disturbed.—M. F.

## WILD GARDENS.

(From "*Belgravia*.")

EXTREMES meet even in gardening, the oldest of the arts. At the time when its practice has become most formal and artificial, delighting in geometrical arrangement of beds and harmonious selection of colours, a revolt is making head very successfully against these refinements, and a reaction has set in towards a more simple and natural method. Lord Bacon would have sympathised greatly with this movement. He speaks of a kindred folly in gardening, "the making of knots or figures with divers coloured earths," with contemptuous indifference; "they be but toys; you may see as good sights many times in tarts." But he is careful to include, in his platform of a princely garden, "the Heath, which I wish to be framed as much as may be to a natural wildness," and then he prescribes for it thickets of Sweetbriar and Honeysuckle, abundance of Violets and Primroses, little mounds set, some with Wild Thyme, some with Pinks, some with Germander, and so forth, "being withal sweet and sightly," till it is easy to picture the philosophic statesman, like the Epicurean poet of Rome, walking amongst his floral treasures and revelling in their copiousness. It is indeed a natural consequence of the present return of the national taste to nature in poetry, painting, and amusements, that the same feature should be prominent in the gardening of the epoch. Men are tired of the grand Italian style, with its terraces and statues, its temples and vases; as well as of the Dutch practice of clipping Yews and Hollies into monsters, according to the dogmas of the topiarian art which was in vogue in England with the early Georges. Even the old arrangement of a garden in formal walks, clipped alleys, and a smoothly shorn bowling-green, which found favour with our ancestors, has been discarded; though Scott constructed a bowling-green at Abbotsford, and the modern game of croquet bids fair to render a level lawn a regular feature in every garden for years to come. Nature, however, like the beauty immortalised by Horace, in her simple native charms, is always most attractive to a pure taste. The influence of fashion may for a time repress her fascinations, but they are too irresistible to suffer more than a temporary repulse. During the last thirty years the tendency of all æsthetic studies has been naturalistic, and men have been strongly tempted by such writers as Kingsley, Tennyson, and, above all, Ruskin, to seek for healthy and unsophisticated inspiration in the beauties of woodland and sea scenery. No wonder, then, that the country has invaded the trim precincts of the pleasure, and that a cherished portion of many a garden at present is the waste and shady corner which used to be its rubbish-heap and eyesore. Mr. Robinson, in his "Wild Garden," (John Murray) has put together an admirable compendium of information of all that concerns the subject. Without invading his province, or trespassing on the charming wilderness of flowers which he teaches us how to create, we purpose to throw out a few practical hints for those who, without much expense, would utilise any waste corner of a garden, and provide themselves with a perennial source of delight. Indeed, the special beauty of a wild garden in our eyes is, that amusement and recreation can be found in it at all seasons.

There are a few principles to be carefully observed in laying-out a wild garden. It matters not how large or how limited be its area, whether it be flat or elevated, for luckily every feature of it can be judiciously made use of, but a single artificial touch is fatal to its beauty. Rockwork that has evidently been constructed, fragments of old masonry, gargoyles, pinnacles, and the like, must be wholly eschewed. They are like "the little rift within the lute" that renders all its melody inharmonious. Such artificialities provoke immediate comparison with the spar-grotto and rockwork-screens of the retired tradesman's suburban villa, or with the groups of sea-weed and shells gummed on paper and suspended round the walls of seaside lodgings, which so greatly offend the eye with their contrast to nature without. Again, the walks which intersect it ought not to be made of gravel, nor must they too be trimly swept, or edged with box or tiles. The earth should only be trodden and beaten into paths, and the leaves which will accumulate on them during autumn ought to lie, unless they become unsightly heaps. Too many rustic bridges again or summer-houses will somewhat impair the wilderness. Nature, it must be borne in mind, is to be stimulated, not improved. If the situation admit, nothing is so charming as to have water introduced, either by a runlet or pond; anything, however, in the shape of a squared basin or formal receptacle is to be studiously avoided. What is being constructed is not a show-garden so much as a haunt dear to meditative minds and lovers of natural beauty; a Paradise in short, as the old Greeks would have termed it; a grove which Romans might have deemed sacred to Faunus, Picus, and the Dryads. Nor must its owner fancy that it can be soon finished; one great charm of the wild garden is, that it admits of every new shrub or flower found in the fields during his rambles being transferred to its precincts, and added to the imprisoned beauties. Thus, besides

being a delight to the senses of sight and smell, such a garden becomes a valuable instructor in the habits of flowers, and an appendage to his regular garden, which no person of poetical or artistic tastes ought lightly to forego. One of the first botanists of the day possesses a most interesting pleasure of this kind. Most artfully and yet naturally constructed, it contains every vegetable curiosity which its owner has discovered or purchased throughout the country. All our native Ferns, and a vast number of the rarer varieties and abnormal "sports," which diligent culture or careful selection has procured, may be seen under its umbrageous trees. A perfect nursery of wild plants, Nettles, Briars, Thistles, &c., all of them most beautifully variegated, and only obtained by years of searching, also flourishes in it. Multitudes of rare and curious plants have been skilfully introduced; the green Rose, whose petals have disappeared and given place to a bunch of sepals; the Umbrella Plant, the Tree Ivy, all sorts of cut-leaved and gaily-painted trees and shrubs, till the collection has become unique, and a ramble through it is a treat to eye and mind alike. A wild garden, when it thus reflects its owner's tastes, is the most charming of home recreations; and whenever he goes away, in some sort it goes with him, for he can always find a new subject to add to his domains. A Stonecrop thus brought, say from Ilfracombe, or a tuft of mossy Campion from Helvellyn, recalls the delight of the summer holiday for many years, as often as the eye falls upon it.

Such a garden as we have described is, however, too full of specialities to commend itself to any one save a real lover of plants, on account of any wonderful contrivance, adaptation, or abnormal structure, which they may exhibit, rather than for their bright hues or rich fragrance. The generality of men and women resort to a garden as to a lounge, and variety in colour and form is, perhaps, all they care about, as these requisites rest the eye and insensibly calm the mind. Let us try, therefore, to suggest a method by which a wild garden which shall possess these qualities may easily be constructed. Around most country houses extends a belt of shrubbery, or a narrow plantation. Either the one or the other can be advantageously used for the purpose by cutting down a few trees here and there, so as to destroy the regularity of the belt, and running a sinuous path through it, which may be broad enough for two persons to walk abreast, or (which is preferable) just sufficient for the solitary rambler. A rustic seat or two must be erected at suitable spots, if possible where a view is commanded, or where the underwood opens out a glade or meadow. Nothing can be better adapted for seats than the trunks of the trees which have been cut down, sawn into a convenient height, as all artificial features must be especially avoided. Those who have seen the composite lengths of rockwork which are piled up at Kew, and covered with Alpine and other plants, will at once recognise the execrable violation of taste which would result were similar constructions to be introduced in a scene consecrated to wild and sylvan beauty. A few hillocks should then be thrown up by the spade in a direction roughly parallel to the path, and of different heights, so as to vary the uniformity of the ground, and secure positions for displaying the Ferns and wild plants, which must next be tastefully dotted over them, while the level ground should gradually be carpeted with Periwinkles (green and variegated), Primroses, Ground Ivy, &c. Nothing more is needed to secure the perfection of a wild garden. We have such an untended realm ourselves (no gardener is ever suffered to touch it), and esteem it one of the greatest solaces of country life. It serves a meditative mind for a library, and the tired spirit for the pleasantest of retirements. Undoubtedly such a pleasure, to be thoroughly appreciated, should belong to a person fond of studying vegetable growth and physiology. As Plato wrote over the door of his study, "Let no one ignorant of geometry enter here," over the portals of the wild garden might aptly be inscribed, "Let no one enter except he know a little botany."

Another wild garden rises before the mind's eye in treating of this subject, which was arranged on a very different and more expensive plan than the last-mentioned one, but which was superior to it in some respects, notably so in the protection which it afforded to Ferns and tender plants. It belonged to a clergyman, who owned a large level flower garden. Being fond of work, in conjunction with his man, he excavated the whole of the lower end of the lawn, to the depth of 12 or 15 feet, in an irregular curve, throwing the earth into banks on the edges of the cutting, and in some places, inside the hollow thus made, in the form of rough heaps. The width of this excavation, which ran the whole length of the garden, was perhaps from 25 to 30 feet, varying every here and there, to prevent monotony. Rustic bridges were thrown over this, and covered with Ivy and Honeysuckles. Trees and shrubs were planted on the mounds; Ferns, Stonecrops, Orpine, and Alpine plants were copiously introduced, and a small runlet diverted from its course was induced to tumble down one side of it, in a mimic cascade, fringed with water-loving plants. It was the parson's delight to lead a visitor

through this, and at the end to cause him to turn a corner and confront what seemed a lake at the termination of the pleasure, but which was in reality an ingenious utilisation of the village horse-pond! The whole idea was unusually well adapted for the purpose for which it was designed, to form a home for our native wild plants, while it formed a distinct and delightful feature of the vicarage garden.

No difficulty will be experienced in getting wild plants to grow and prosper in some such wilderness as we have endeavoured to delineate. Save in very dry seasons, they need not even be watered; the trees overhead warding off the direct rays of the sun, and securing them a plentiful supply of moisture by the passing vapours which they distil, and drop from their leaves on them. Where Ferns are meant to grow luxuriantly, however, it is as well every now and then to give them a copious watering at nightfall. Every autumn the Primroses, Violets, &c., may be divided, and the offshoots planted at some distance from the parent-stock. It is advisable also to suffer the dead leaves to lie where they fall, as they shelter the tenderer species during winter, and enrich the ground afterwards by their decay. Raking them up involves too often tearing up well-rooted specimens. Indeed, it cannot be sufficiently impressed upon the lovers of wild gardens that gardeners should never be allowed to enter them. They are certain to think their masters lunatics for preserving and propagating weeds, and neglecting the ribbon beds and geometrical arrangement of bedding-plants which lie so close to their hearts, but that does not much signify if they can only be kept out of the wilderness. In some portion or aspect of the wild-flower garden all the native plants which please its owner will prosper; it will be for him to learn how to adjust the space at his command to the conditions each family of them requires. And this renders work in the wild garden the best possible lesson in practical botany.

A few words must be added, in conclusion, on the choice of wild plants for the garden. Bracken and Ferns will, of course, be largely introduced, with Ivy and Honeysuckle overhead. Foxgloves of different colours (the bees will effectually mix the seed annually) are especially effective on the outskirts. It will be found that they will not prosper well in too shady spots. Periwinkles, Ground Ivy, the Veronicas, Violets, &c., will furnish the necessary tints of blue; while the Pink, Campion, Lychnis, Soapwort, &c., will secure shades of red. Snowdrops (single) and Daffodils (also single) will flourish well on elevations in sunny, open spaces. Primroses, however, are unrivalled for beauty in spring. Plant as many of the native straw-coloured flower as can be conveniently procured, and intermix here and there a few plants of darker shades—pink and purple; in a few years they will increase surprisingly, and, owing to the bees mixing their pollen, will flower of every shade between pure white and the deepest crimson. The wild garden is never more attractive than in March and April; when these are blossoming, Wallflowers may be sparingly dotted about; *Atabis* and *Iberis*, *Alyssum* and *Anbrietta*, will variegate the more open spaces; *Honesty*, with its mauve flowers and curious bladder-like seed vessels, is indispensable; the *Sunroses* and *Chickweeds*, but especially the *Mouse-ear*, to furnish "Forget-me-Nots for happy lovers," must by no means be forgotten. Thus will its possessor rejoice in a garden which offers delight to sight and smell every month in the year, which takes care of itself, nay, which, without any expense, annually grows more beautiful.—*M. G. Watkins.*

#### SPRING.

SEE! the cautious Oak at last,  
Owning angry Winter past,  
Spreads his smiling leaves—in haste  
Lest the roving woodsman dread,  
Haply holding him for dead,  
Plying horrid wound on wound,  
With gleaming axe should bear him groaning to the ground.  
Then, with emulous blossoms gay,  
Snowy Chestnut—snowy May  
Laugh by every woodland way,  
Then the blushing Lilac kisses  
His *Laburnum's* golden tresses.  
And, while sheep-bells mingle sweet  
With the new-born lambkin's bleat,  
Loud the pairing thrushes sing,  
"Winter-time has turned to Spring."  
Now to Man that happy Voice  
Cries in turn "Rejoice! Rejoice!  
Come, O come! for now at last  
Lo the Tyrant-King has passed,  
Fear no more his snows and frost,  
Reck not of his tempests rude,  
Winter o'er the seas has crossed,  
And his storms are all subdued."

*A. P. Graves, in Fraser.*

## GARDEN ARCHITECTURE.

BY NOEL HUMPHREYS.

THERE is no more difficult task in ornamental gardening than the blending of architectural forms effectively and harmoniously with general garden scenery. If the principal object be of considerable dimensions, it necessarily requires supporting with such subsidiary features as will cause it to blend pleasingly with the naturally irregular forms surrounding it, whether of trees, turf, or walks. As an unfavourable example of a combination of the rigid lines of architecture with shrubberies, curved walks, and sloping turf, the huge mass of lumpy balustrades, basins, and fountains at the head of the Serpentine, in Kensington Gardens, may be cited. Its features are so crowded, so heavy in character, and present so many formal repetitions, that the effect is that of an incongruous and disagreeable patch in the midst of fine surroundings. It terminates abruptly on every side, and though not without merit in some of its individual features, is, as a whole, a blot upon the scene which it was intended to embellish. Very different is the result secured by a design of somewhat analogous character in the gardens of the Luxembourg, at Paris, of which the annexed engraving is a careful representation. The design and execution of this artistic piece of garden architecture belongs to the period of Louis XIII., and the lines of the architectural composition have the variety combined with nobleness which distinguishes many of the works of that date. They are, moreover, almost invariably enriched with figures in such a manner as to form a necessary part of the device, and also with an infinite number of those rich and appropriate details, which, in works of a more recent date, were generally pared away, in affectation of "Grecian" simplicity. In the work in question, such details as those referred to form an important feature of the composition. As being a structure devoted to the display of water in an ornamental manner, river deities are introduced on each side of the pediment pouring forth a sculptured representation of water, which is supposed to form itself into stalactites as it falls, and so becomes part of the decoration of the edifice. The same feature, water hardened to stalactitic forms, is made the chief decoration of the columns and of the panels between and beneath them. Well executed statuary further embellishes this handsome design for an architectural fountain; and its

appropriate character is further enhanced by the five deep ledges, of semicircular form, over which water continuously falls, in thin, glassy sheets, into a basin surrounded with simple stone dressings of massive proportion.

A fountain of this kind is generally employed to conceal the small extent of a certain portion of the grounds, or, as is the case in the gardens of the Luxembourg, to keep out of view unsightly features. The great difficulty in a case of this kind is to make an object of such magnitude and so much architectural pretension blend harmoniously with the ordinary features of the surrounding grounds. This has been so

successfully effected in the present instance that it becomes interesting to observe and analyse the methods employed for the purpose. In the first place the necessary formalism of the architectural features are gradually softened off by a series of stone vases filled with flowering plants, which are ranged in line along the stone coping of the basin. On the opposite side of the walks to which they form bordering objects next the water, trained Ivy comes into play; in order to finally blend the formal with the natural by means of festoons trained from trunk to trunk of a short avenue of Planes, the foliage of which is left entirely uncropped. These artificial and regularised festoons, combined with the regular training of the Ivy about the lower part of the Plane trunks, up to the height from which the festoons are suspended, form such a gradual and judicious softening of formal features into the masses of untrained greenery of the adjoining shrubberies that no incongruity is felt, even by the most artistically cultured eye, and the formal fountain becomes at once an acceptable and agreeable feature in a scene to which it adds variety and interest, instead of being, had it been crudely introduced, an obtrusive and disturbing feature.

If some such principles as those described in the

present instance were carefully considered before introducing temples, or terraces, or fountains into rustic scenery, we should see fewer of the violent and tasteless anomalies which so often disfigure our gardens and parks, both public and private, than we now do.

Much anxiety is felt in Russia regarding the destruction of forests, which proceeds very rapidly, and threatens to deprive the country of one of the most valuable of its export products—wood for building purposes.

Fountain in the Luxembourg Gardens.

## FALLEN LEAVES.

Read by Professor Owen before the Hampstead Literary and Scientific Society.

THESE withered glories of the summer, their fall in the sere and yellow state of autumn, are symbolic. There are vivid and noisy pleasures; there are those also of the quiet kind, and not the less pleasing, even perhaps more cherished in memory, when tintured with some sadness: and in such a mood have I watched, on a still, calm day in latter autumn, when no breath of wind was stirring, the leaves settling straight down in silent tremulous fall, "one after one," suggesting and recalling the friends and loved ones that had successively passed away in peace! Yet it is not altogether surcease and loss; the leaf-fall better understood may suggest brighter associations. The poet, indeed, expresses, in his gifted strain, the common thought which associates the phenomenon of the fall of the leaf with the transitory tenure of all life—the inevitable course of youth to maturity and decrepid age—of uplifted waving greenness and freshness to the sere and withered return to earth and dust. Ask a friend why the leaves fall in autumn. He will answer, "They fall because they die." If the premature phenomenon in an ornamented square of smoky London have suggested the thought, he will connect it with the wearing-out of energy that has done its work, its duty under difficulties—not perhaps without a passing wish for a like repose "from the weariness, the fever, and the fret" of competitive struggle and toil. And when the phenomena of defoliation are witnessed under the more favourable circumstances of the rural garden, they may be compared, as by my old friend London, with the sloughing of dead parts—a state initiated in the leaf "by the cold of autumn and accelerated by the frosts of winter." And such may still be the common notion; it was long my own.

But some summers ago I was led to think a little closer into the matter by an effect of a thunderstorm which took place in July. The lightning struck a tall Elm tree, one branch of which it killed; the leaves became brown, and died, but they did not fall. When autumn came, their bright brethren, fading to a similar tint, fell. When winter frost had set in, and the crisp snow overspread the park like a gigantic bride-cake, the Elm was all stripped, save that thunder-stricken branch, and the only leaves that remained were those that had been killed in midsummer. They were never shed: they rotted off bit by bit. This led me to examine the nature of the attachment of the leaves in some trees in my own garden. The expanded base of the petiole, or leaf-stalk, is attached by continuity of woody tissue, including parenchymal cells, sap-vessels, air-vessels, and the cuticle of the bark, continued from the branch into the stalk. The Plane and Sycamore are good subjects for the examination. Soon a delicate line of the cuticle indicates the coming place of separation; soon also, in the Sycamore and most of our deciduous trees, a tiny bud peeps from the axil or angle between the leaf-stalk and stem. Now, next, I may remark that, watching the autumnal period of the fall, I observed that defoliation was accelerated, not so much by early frost as by unusual warm and open weather in November; especially with the Plane-tree, that many of the leaves which naturally fall were not in the "sere and yellow" state, but were green, as full of life. Even now you may see the difference of colour between such leaf sheds ~~now~~ living, which I hold in my right hand, and the ordinary withered leaf ~~in my left~~. My examination, at this period, led me to perceive that the immediate cause or stimulus of the fall was the growth of the baby-bud at the base of the leaf-stalk, which, pressing on the tissues at that part, caused their disintegration and disappearance in a manner analogous to that of "absorption" in the animal economy. Pursuing the examination in different kinds of deciduous trees, I found that the mother-leaf was pushed off in different ways; and that these represented the different ways in which deciduous teeth are displaced by their successors. Thus, in the Plane tree the bud pushes vertically up the middle of the base of the stalk; while in the Sycamore it excavates obliquely the side of the base. The shed Plane leaf shows a conical cavity at the detached part of the petiole, like that at the base of a shed-tooth of the crocodile; the fallen Sycamore leaf shows an oblique lateral depression, like that at the base of the shed tooth of a lizard. In the Plane tree, the central part of the parenchymal cells attaching the stalk are first pressed and successively yield to the growing bud, the disintegrating process spreading to the periphery, not along a transverse, but a conical surface; although, by a sort of sympathy, the epidermis, ere the killing process reaches it, indicates the line of coming solution of continuity. The leaf-stalk may for a while be supported by, being sheathed upon, the bud, after it has been wholly separated from its stem; and the process of this separation provides against any rupture or "bleeding" from sap-vessels. Nothing can show greater contrast than the separated surface of a leaf-stalk thus orderly detached and that of one violently torn off. Mild weather, accelerating the bud-growth, pushes off the leaf before its time; early frost, checking the bud-growth,

may turn the colour of the leaf, but delays the fall. Young leaves killed by vernal frosts rot off, but are not shed entire.

You may ask how it goes with Evergreens? Essentially and in the main such varieties depend, as in the Holly and evergreen Oak, upon the time of development of the leaf-bud: the leaves equally falling, but in early summer, when the new buds expand, instead of in the late autumn. I speak on this point, however, with diffidence, in the presence of some friends to whom botanical science owes real progress. They well know the endless variety in the structure and development of leaves. How inapplicable—or seemingly inapplicable—is the theory of the bud-growth to the shedding of those lovely, complex, tripinnatifid leaves of some of the Acacia family; how in Gleditschia—*e.g.*, each leaflet acquiring its golden hne flickers away, leaving the stalk to be the last to fall: how in the case of the filamentary leaves of the Pine tribe, although there is an annual shedding, yet many stay for two or more years before they fall. What I chiefly had in view was to show that, in respect to those ordinary deciduous trees which give us the autumnal fall of the leaf, it is not because one leaf dies, but because another leaf is born: it is a phenomenon that may be associated with perennial and ever-springing life, rather than with decay and death. It is a process, therefore, which, if it naturally at first excites sentiments of sadness, may and ought, when rightly understood, to call up a cheerful and grateful sense of the power that provides ample compensation for seeming loss.

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**Flower Garden.**—Flower borders and beds must now be kept neat and clean. Grass lawns should be mown about once in ten days, rolled and swept. Gravel walks should also be cleaned by means of hoeing and raking, or hand picking, and, if necessary, top-dressed with fresh gravel. Deficiencies, if any, amongst herbaceous plants should be made up from the reserve ground; or large crowns that have not hitherto been disturbed may yet be taken up, divided, and transplanted. Mulchings of all kinds must be either removed or concealed under an inch deep or so of soil. Plants of Pampas Grass, the leaves of which have been tied together to protect the crowns, should be divested of their fastenings, as should also Yuccas. Stake Pæonies and other plants likely to be injured on account of want of support. Thin such annuals as have been sown too thickly in flower beds, and transplant Saponaria, Nemophila, Candytuft, &c., from the seed-beds to where they are intended to bloom.

**Bedding Plants.**—All plants required for summer decoration should now be propagated; yet a few extra plants should be kept in store in case of failure, and for this purpose late-struck cuttings are useful. Where open, airy sheds exist, Pelargoniums may be placed therein, or in frames, or between glass houses, or, if previously well exposed, they may even be set under the shade of thickly-branched trees. When water is required, it should be given in the forenoon, for if watered late in the day the plants are more apt to suffer than if they were comparatively dry. Remove the sashes during fine days from frames containing Calceolarias, Verbenas, Ageratums, &c., but ~~close~~ and tilt them up a little at night. Such Dahlia cuttings as are now ~~ready~~ ready, plant in frames, and keep them a little close for a time, but after growth has commenced expose them freely and water liberally. The roots from ~~which~~ the cuttings have been taken should also now be planted in frames, and all shoots except three rubbed off each plant. Prick off into boxes or light rich soil, consisting of equal parts of leaf-mould, loam, and washed sand, such seedlings as are yet in seed-pans. Alternantheras, Coleuses, and Iresines may yet be propagated freely, because they have a longer time to remain indoors than plants of a hardier character. Some sub-tropical plants, such as Wigandias, Solanums, Ferdinandas, &c., raised from cuttings this spring, may be potted into 4 or 6-inch pots and kept in them until next spring, when they may be forced for cuttings. All sub-tropical plants for the forthcoming season must yet be kept rather warm and in a growing condition, taking care, however, to keep them near the glass, and to admit fresh air to them as freely as possible.

**Forcing-House.**—Of *Hoteia* (*Spiræa*) *japonica* have successional supplies, one in cold frames, another in an intermediate pit, and a third in the stove or forcing-house; 6-inch pots are quite large enough for them, good roots being the main cause of success. Syringe the furthest advanced ones twice a day, until they come into bloom; the pots containing them may be placed amongst young Ferns, which will thrive perfectly well under the shade of the *Hoteias*. Of Coleuses pot on some of the best kinds for specimens, and set them in a position near the glass; the sheets should be well pinched, and a

pyramidal form aimed at. Of *Rhodanthe Manglesii* remove such as are coming into flower to the conservatory, and pinch the tops out of such plants as are advancing too fast. Sow a few more seeds of this fine Everlasting for succession. Of Musk sow some seeds in a pan of light soil, prick off seedlings, and pot the plants pricked off a few weeks ago. Old roots, which make as good plants as seedlings, may also be potted. A few plants inserted in a wire basket, grown in heat for a time, and afterwards transferred to the conservatory, have a fine appearance. Divide some plants of *Isolepis gracilis*, pot the divisions, and grow them for a time in the forcing-house. Sow some Globe Amaranths, and prick or pot off plants obtained from previous sowings. Sow another lot of Balsams, and pot them into sixty-sized pots, as soon as they are fit to handle; a little bottom heat, and a place quite close to the glass are of great importance to them, and at each potting plant them a little deeper than they were previously, as they emit roots freely along the stem. Start Gloxinias and Achimenes in succession, in the warmest part of the house, and remove them to the conservatory as they come into bloom; Achimenes strike as freely as Verbenas from cuttings.

**Orchids.**—In the East Indian house maintain a night temperature of from 65° to 70°; 75° will do during the daytime, allowing a little more during bright weather. In the intermediate or Cattleya house the heat may range from 60° to 65° at night, with a rise of 10° during the daytime, or 15° in the case of strong sun-heat; in the cool or Odontoglossum-house maintain a temperature of 50° at night, and allow a rise of 10° during the day. As the plants are now in a growing state, a moist atmosphere must be kept up by means of damping the floor, stages, and side walls, and syringing the plants twice a day in bright weather. Keep also the evaporating pans full of water. If water lodges in the crowns of any plants, invert them, so as to permit it to run out. Shading from strong sunshine must also be attended to, so as to protect the young growths, and to preserve the beauty of the flowers. All Orchids requiring top-dressing or shifting should receive that attention at once, and water should be plentifully supplied to such as are growing freely. Keep down insects, for if they are allowed to establish themselves just now they will cause continual annoyance throughout the remainder

**Ferns.**—Remove out of doors, and loosen the surface may be on deciduous kinds the same time clean and neat. Roots of these making it at transplanted in shady nooks. Hardy Ferns wintered in frames or greenhouses should have their old fronds cut away, the mould on the surface of the pots cleared off, and the pots themselves either plunged in the fernery in the open air, or the plants turned out of the pots and planted in the soil permanently. In some cases it may be advisable to repot a few, and to keep them growing for conservatory decoration, or for planting in the outdoor fernery, after their fronds have been formed indoors. Greenhouse Ferns are now starting into growth, and if any remain yet unpotted, which require a shift, attend to them at once. Stove Ferns, as a rule, are in a moderately advanced state; consequently heat, moisture, and condensed light, by means of shading, are necessary for the perfect development of their fronds. Filmy Ferns must now remain undisturbed, closely shaded, and sprinkled overhead every morning and in the evening, too, if the weather is very bright and warm. Maintain an equable temperature about these plants by tilting up the lid of the case in which they are growing a little during the daytime and closing it at night.

**Window Gardens.**—Prepare boxes for window plants. If they are small, they may possibly be accommodated indoors for two or three weeks prior to placing them outside, in which case the plants will get well established before they are subjected to outdoor treatment. The boxes, pots, or pans to be used for window plants should be perforated sufficiently to allow superfluous water to escape readily. A layer of potsherds, small chips of brick or sandstone, should be put in the bottom, then the roughest of the soil, filling up with the prepared compost. Good fresh loam mixed with leaf-mould or some well-decayed manure makes an excellent compost, capable of growing almost anything. Pelargoniums of different kinds, but particularly the green-leaved plain and zonal sorts, also the white variegated-leaved varieties, are all suitable for window decoration, as are also Lobelias, Heliotropes, Fuchsias, Tropaeolums, Mignonette, and many other plants. Ivy and likewise Ivy-leaved Pelargoniums are excellent plants for this purpose. Succulents, such as the different kinds of Mesembryanthemum, are likewise very suitable for sunny windows; and Musk, Calceolarias, and similar plants, for positions where they can be kept moist. The variegated Iris is one of the prettiest plants that can be grown for the ornamentation of a window, and its leaves remain a long time unwithered. Perennial hardy plants, with the exception of Creeping Jenny and one or two others, are but short-lived when so treated; but many annuals may be employed with

advantage for windows, and, when they have done blooming, they can be pulled up and thrown away, thus making room for Pelargoniums and similar plants, which form a useful succession to them.

**Pine-apples.**—Where Pines are planted out in pits, suckers put in during winter had better now be lifted and transplanted farther apart, as should also plants that are expected soon to show flower. Give water freely now, and keep up a brisk temperature. No shading is necessary, except in the case of newly transplanted plants. Maintain a moist atmosphere by means of damping the paths, walls, and beds, and gently syringe plants in pots in fine weather. In the case of those planted out, a sprinkling from the watering-pot, when watering, will be sufficient.

**Vines.**—New Grapes from pot Vines are now plentiful; but care should be taken not to cut them before they are quite ripe. Keep the house in which they are growing moderately dry, but enough water must be given to the roots for the proper sustenance of the plants. A little ventilation should be allowed day and night in mild weather, the requisite temperature being maintained by means of fire-heat. Thin both berries and shoots as may be necessary, and maintain a brisk moist temperature in houses in which fruit is swelling. Young Vines in pots that were cut back and started again this spring should be trained upright near the glass, so as to thoroughly mature their wood. Shift Vines propagated this spring into 6, 8, or 10-inch pots, and give every encouragement for the production of strong, firm, and well-ripened wood.

**Figs.**—Such plants in pots as are ripening their fruit should get sufficient water to sustain a vigorous and healthy constitution, but the supply must be less copious than if the fruit was only swelling. To trees in borders as well as in pots apply some manure water, but should the plants exhibit a tendency to gross growth, water only with pure water. Stop the young shoots at the fourth joint, and do not overcrop.

**Peaches and Nectarines.**—This season, as a rule, has not been favourable to Peaches, many having fallen off while stoning. Those that have passed that stage should have a temperature of from 60° to 65° at night, allowing a rise of 15° during the day. Attend to budding the young shoots and the thinning of the fruit. Syringe the plants twice a day, give air freely, force moderately, and economise sun-heat in preference to allowing too much fire-heat.

**Cherries.**—For these scarcely any fire-heat will be necessary, but they have got over the stoning period, but a little warmth indeed, ventilation during the morning will be required. If the item in Cherry forcing.

**Melons.**—Apply fresh linings to frames in which the temperature is beginning to decline. Fertilise the flowers both in pits and frames. Melons lately planted should have their shoots trained out, so as to allow them to have abundance of light, and all laterals should be stopped. Good healthy foliage should be encouraged. Prick off or pot singly succession plants, and finally transplant them before their roots become cramped in the pots.

**Cucumbers.**—Train, stop, and regulate the shoots of these, and do not permit more fruit to remain on each plant than it can bring to perfection. Apply fresh top-dressings to the beds if the roots are making their way thickly through the soil; water abundantly, and syringe freely. Take off cuttings and strike them, for plants obtained in that way are more prolific, and come into bearing sooner than seedlings; artificial fertilisation of the blooms is unnecessary, except in the case of any that are required for seed, in which case one fruit on an old plant is sufficient.

**Strawberries.**—Early plants of these have, in many cases, produced small fruit this season, but now that the weather is brighter and warmer, better results may reasonably be expected. Water such plants as are ripening fruit sparingly, and transfer them to the fruit room if it be desired to keep the fruit in good condition for a few days longer than it otherwise would be if kept in a warmer situation. Introduce succession plants to the forcing house, in all cases keeping them close to the glass. After the fruit has set and until it begins to colour, apply manure-water occasionally. If there are many flowers on each truss, and the fruit is well formed on the portion nearest the base at the stalk, pinch off the point of the truss, so as to throw increased vigour into the already formed fruit, the best of which is always produced from the lowermost flowers.

**Hardy Fruits.**—Finish grafting and also pruning of all kinds. Gradually disbud trees on walls as soon as the shoots are sufficiently advanced for that purpose. Attend, also, to the protection of the blooms. Rub away such shoots as rise from the base of Gooseberry bushes, and thin those on the bushes themselves sufficiently to permit a free circulation of air. If this is done now much time is saved, and

the operation can be conveniently performed; yet it must be remembered that abundant foliage is necessary for the production of fine fruit.

**Kitchen Garden.**—Asparagus is now obtained from the open air. Some leave a shoot or two on each plant uncut, whilst others cut all away until the 1st of June. The latter is the proper way; though, under that system, fresh plantations must be made more frequently than if a more natural course was adopted. Thin Parsnips, but not too much at first. Draw earth to Potatoes as they appear above ground, and lightly stir up the drills containing late sorts. Keep up a regular succession of Peas by sowing at proper intervals seasonable kinds, in quantities sufficient to meet the demand. Plant out herbs of different kinds, and transplant Lettuce raised in frames. Sow Spinach in succession, also small saladings. Transplant Lettuces in any empty space, and prick out Celery in a bed of rich soil 6 inches deep, on a hard bottom and in a warm position. Sow the main crop of Beet, if not already done. Encourage early Cauliflower by drawing some earth around the plants, so as to form a basin for the reception of manure-water, and keep the hoe at work amongst all growing crops.

#### ANCIENT EMPLOYMENT OF FLOWERS.

With Mr. Leo Grindon's statement that, in the classics, there is "no allusion to the nosegay or bouquet," I cannot agree. Has Mr. Grindon forgotten the "*copia narium*" of Horace? These words suggest to me a nearer acquaintance with the sweets of the flower-bed than can be formed from merely walking past them. It is hardly to be supposed that the sensuous Roman of both the Earlier and the Later Empire would content himself with inhaling the distant fragrance, borne on the breath of the morning or the evening zephyr, without an attempt at a nearer appropriation of the sweets which—with an unwonted, and therefore a more attractive, modesty—presented themselves to his all-devouring sense. Such, at least, has never been, not, I shall say, the characteristic of it, but the exception to, all we have known of the insatiable appetite for extreme indulgence which will for ever stamp a race whose highest enjoyments were, at the zenith of their prosperity, with the mob, "*panis et circenses*;" and, in the highest ranks, as Juvenal too truly tells us, the hot breath and the short-lived pleasures of the twilight-covered "*fornices*" of the Subura. No; I give the *Romans juvenis* credit for one thing, and that is—that they plucked every flower that pleased their fancy. Is it to be supposed that the "*juvenis*" who had assumed the "*toga virilis*" would consider that a sufficient recommendation in the eyes of the voluptuous and deeper-seeking Roman maidens? Hardly! As in the present day, the tailor's dearest accomplishment must be supplemented at ball or regal *levée* by the indispensable "*button-hole*," and as Madame Chose's most lovely things must be made far lovelier still by a floral trimming and a hand-holding of a bunch of blossoms, so we cannot rationally conclude that nosegays were quite unknown to the ancients. Mr. Grindon's own quotation—

"*Qualem virgineo demessum pollice florem*  
*Seu mollis color, seu languentis hyacinthi*" (flowers not mentioned as used for chaplets)

—so sufficiently confutes his, perhaps not well-considered, notion on this subject, that I will not further pursue my remarks. I shall only say that, if we possessed a full glossary of the familiar and conversational words of the Augustan and post-Augustan age, which the classics, in their purism, have not preserved to us, I should not be at all surprised to find that "*copianarium*" had become the recognised word for a nosegay, more especially as its bi-dactylic form would, in its softly-flowing syllables, recommend it not only to the progenitors of the "*Lingua Toscana*," but also to the ingenious, *cæsura*-in-the-fifth-place-neglecting, and distraught makers of such hexameters as

"*Perturbabantur Constantinopolitani.*"

W. M.

**New Tying Material.**—A material for tying purposes, said to be superior to anything hitherto in use, is noticed in the current number of the *Revue Horticole* under the name of *Natte Müller*. M. Müller, nurseryman, Strasbourg, who first brought it into notice, states that it was some time since imported from Japan into Germany for the purpose of paper-making. This speculation, however, having

failed, and the material coming again into the market, it fell into the hands of M. Müller, who was struck with its adaptability for horticultural purposes, as it possesses all the good properties of toughness, pliancy, and softness. On submitting a sample to Professor Koch, M. Müller was informed that it was obtained from the entice of the leaves of the Palm, *Raphia tédigera*. If this is the case, M. Carrière remarks that the account of its importation from Japan must be a mistake, as all the species of *Raphia* are found only in very warm countries. From whatever source it has come, M. Carrière endorses M. Müller's high estimate of its value to gardeners, and remarks that, with all its pliancy and softness, it is so tough that, without being moistened, it can be tightly knotted without breaking, exactly resembling a piece of twine in this respect. It occurs in strips of about 5 feet in length, and can be sub-divided into portions as fine as thread, which preserve all the tenacity of the larger pieces. A branch *dépôt* for the sale of the *Natte Müller* has been opened at Paris in the establishment of M. Loise-Chauvière, marchand-grainier, 14, Quai de la Mégisserie. In this country it is sold in the trade under the name of "*Roffea*." For grafting purposes or for general plant tying it is cheaper and much superior to either Russia or Cuba bast. Of the latter, there is always a lot of harsh unusable material, even in the best samples; but there is no waste at all in *Roffea*, as every bit of it is equally good.

**The Yellowstone Valley Park.**—Early last year the United States Congress set apart the region about the head waters of the Yellowstone River as a national park; and a New York paper states that the superintendent, Mr. Langford, has issued his first annual report. It appears that a large part of the Yellowstone region remains yet to be explored. Access is obtained to the park from the territory of Montana, for although a portion of the region is included within the limits of Wyoming, a perpendicular wall of basalt, in some places 5,000 feet high, forms a barrier which renders all access from the direction of Wyoming impossible. At present visitors are compelled to enter the Yellowstone region on horseback, and over wild and difficult bridle-paths. Carriage roads, however, can be constructed without much difficulty, and there are no insuperable obstacles in the way of laying down a railway, by which the park may be rendered still more accessible. The wonders of the Yellowstone are insignificant; hot springs, with which the geysers of the region are associated, are numerous, and mud volcanoes; falls of 350 feet in vapour springs, and mud volcanoes; falls of 350 feet in vapour springs; canons of 5,000 feet in depth; streams thickly impregnated with lime; and mountain and rock scenery of the most imposing character. In the yet unexplored regions of the park other marvels may be discovered, for there seems no limit to the freaks which nature, aided by unlimited supplies of water, both hot and cold, and of steam at incalculably high pressure, has played and continues to play in this wonderful region.

#### COVENT GARDEN MARKET.

APRIL 25TH.

**Flowers.**—Azaleas, Cytisus, Pelargoniums, Hoteias, Roses, Hydrangeas, &c., form the bulk of plants in pots now in the market. Herbaceous Calceolarias are, however, beginning to make their appearance, and Ferns and Lycopods are furnished in abundance. Cut flowers consist of Stephanotis, Gardenias, Camellias, Azaleas, Cinerarias, Roses (particularly *Maréchal Niel*), Heaths, Epacris, Hibbertia Readii, Acacias, Orchids, &c. Callas are also supplied, both in the shape of plants in pots and that of cut flowers. Of spring flower-roots, and, indeed, of herbaceous plants in general, there is a considerable quantity, as well as of hardy climbers, for which there is always a good demand.

**Fruit and Vegetables.**—French and other continental supplies of fruit are well kept up, but home-grown produce in that way is somewhat limited. Good English Pines are scarce, and only one consignment of Pines has been received from St. Michael's this week. English-grown Grapes, both old and new, are good, and Cucumbers are already getting quite plentiful. Radishes, young Onions, Rhubarb, Seakale, Asparagus, &c., constitute the bulk of home-grown vegetables, which are still somewhat scarce and dear.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Cobs, per lb., 2s. to 2s. 6d.; Grapes, hothouse, per lb., 15s. to 25s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 6s. to 12s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 6s. to 10s.; Strawberries, per oz., 9d. to 1s. 6d.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 5s. to 10s.; French, 6s. to 15s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, young, 1s. 6d., old do., 6d.; Cauliflower, per doz., 3s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 6d. to 2s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz. 1s. to 2s.; Mushrooms, per pottle, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 3s. to 6s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 4s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 5s. to 8s.; Potatoes, per bushel, 4s. to 8s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsify, do., 1s. to 1s. 6d.; Savcys, per doz., 2s. to 3s.; Scorzonera, per bundle, 1s.; Seakale, per basket, 1s. to 2s.; Shallots, per lb., 5d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, old, per bunch, 3d. to 6d., young do. 2s.

## THE GARDEN.

—o—o—o—

"This is an art

Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

—o—o—o—

### AMONG THE ROSES.

I PROPOSE to offer from time to time to the readers of THE GARDEN such notes and thoughts about Roses as may be suggested by the flowers themselves blooming in or out of my greenhouse, and, like the tea-bibbing dame in "Pickwick," "a-swellin' wisely afore my werry eyes." If, sometimes, these commentaries are hurriedly written, as by one whose engagements are pressing, and whose mind is musing upon many things, I can assure the brotherhood and sisterhood, who love the Rose, that they may rely upon my veracity, however much they may criticise my style. I shall only describe what I see, and draw, not upon my imagination, but from Nature.

So come into the garden, Maud, and let us first take a peep into this wee conservatory, which contains my Roses in pots. I will not dwell upon the older varieties; but two I must select from that bright throng, as specially and invariably beautiful. And, as we gaze admiringly upon those large, globular, pendulous blooms of *Souvenir d'un Ami*, with its broad blushing petals and its lustrous leaves, are we not sadly reminded, we elder Rosicrucians, of a friend whom we shall see no more among the Roses. No subject of the queen of flowers had a more loyal love than Charles James Perry, not one of her judges was more wise or more righteous than he. Many hundreds of the best Roses grown in England have we criticised together as censors; often have we met as competitors—always as friends. There was ever a kindly pleasantness in his face and in his speech—something of the brightness and the freshness of the garden which he tended so fondly at his charming home among "The Cedars;" and many of us will miss, not only his excellent discrimination as an arbiter (there are not, I believe, a dozen men living who understand the merits of a Rose as he did), his novelties as a raiser (in *Verbenas* matchless), his successful displays as an exhibitor, but his genial society as a cheerful companion and an earnest, honourable man.

So we will pass on, with a sigh and with a hope, to the other Rose, which I would particularise from the crowd of old favourites, as being, perhaps, the most satisfactory of all which are grown under glass—the *Maréchal*. I call it most satisfactory, not only because of its beauty, its golden beauty, its symmetrical form, and exquisite fragrance, but because of its adaptation to all requirements, blooming abundantly, as with judicious treatment it will, in a pot of moderate size, when but a twelvemonth old, or in a couple of years, when planted in a rich border, making shoots 18 feet in length, and giving scores of its glorious Roses all along the pillars and rafters of its home. I have a plant now, little more than a year old, which is trained on a wire balloon some 4 feet in height, and is covered with blooms; in short, the growth of *Maréchal Niel* upon the *Brier* is wonderful. Some three weeks ago, Mr. Prince, of Oxford, sent me a box containing, not four-and-twenty blackbirds baked in a pie, but four-and-twenty seedling *Briars* with *Maréchal Niel* buds, just ready for a start, in each. I potted them in soil which a Rose-grower would almost like to eat, placed them in a warm vinery, and I have just measured several of the shoots—18 inches of bright, healthful growth.

We will not dwell on climbing *Devoniensis*, although it is in my opinion the second Rose in merit for culture under glass (I am leaving *Cloth of Gold* out of the question), because it requires a large space for the development of its beauty, and therefore is not everybody's Rose; but we will proceed to the newer varieties. Of those sent out by the French growers in the autumn of 1871, and by the English in the spring of 1872, I can commend the following:—Baronne Louise Uxkull, a grand Rose, with the abundance of petal we Rosarians love, and much resembling *Madame Boll* in flower, leaf, and constitution. It is pleasant

to note that many of the 1872 Roses have a healthful vigour, more like that of the old Hybrid Perpetuals, *Madame Laffay*, *Baronne Prevost*, and *William Jesse*, than some of the more recent novelties, which are the offspring of inter-marriages between the Hybrid Perpetual and the China Rose. *Baronne Louise Uxkull* is also a very fragrant Rose. *Etienne Levet*, a charming Rose, of very regular outline, and having its petals arranged in the *Camellia* pattern, a bright rose colour, with fine foliage. It is, in stable phrase, "a stayer," and as a show Rose will, I think, prove worthy of its name. *Stephen*, and be crowned as a conqueror. *Madame George Schwartz* (these successful raisers of Roses naturally and rightly give their own names, or the names of their kinsfolk, to their most promising *débutantes*) is a very handsome lady, large and lovely, and quite worthy to hold office in the Court of Queen Rose; *Lyonnais*, a light silvery pink, with abundance of petal, somewhat reminding us of *Monsieur Noman*, and likely, I prophecy, to be successful on "the stage"; *President Thiers*, a noble flower, far more king-like than republican, albeit fiery red, sure to be a favourite, like his synonym, both in private and in Assemblies of the people (commonly called *Rose Shows*); and lastly (for I have not as yet bloomed *Docteur de Chalus*, *Jeanne Gros*, *Madame Hippolyte Jamain*, or *Richard Wallace*, though I have received commendatory reports), let those who say that our new Roses are deficient in perfume, apply their nasal powers, to sniff and not to sneer, over *Souvenir de Julie Gonod*; and if *La France* has not already made them ashamed of their calumnies, now, at all events, they must retract, unless they be "sans nose, sans everything."

But I am forgetting the tea-scented Roses, and they are deserving of much commemoration. I have not flowered *Madame Jules Margottin*, but *Madame Marie Van Houtte* is quite one of the freest, prettiest "Teas" in cultivation. A small plant, which only came to me last April (a gift from Mr. Bennett, of Salisbury), is now just finishing a second crop of flowers, and growing away in all directions for another efflorescence. The flower is of good size and globular form, pale yellow, with a pink tinge on some of the outer petals. I strongly recommend it as a pot Rose. My plant of *Madame Cecile Berthod* is not a strong one, but the Roses are such a bright clear yellow, that I infer something very attractive when there is more vigour.

Of this year's Roses, I have heard favourable accounts, from very reliable Rosarians, of *Monsieur Claude Levet* and *Monsieur Pierre Seletzsky*, and I have seen a small bloom of the much-lauded *Madame Lacharme* (on a plant kindly sent to me by my friend C. Turner), and also some full-sized petals from a flower grown at Slough. Whether this "*White Jules Margottin*" will prove to be "the best white Rose in cultivation," and so create as much sensation as *Wilkie Collins*' "*Woman in White*," appears to me very questionable. I believe that the Rose will be an acquisition, but it is a French white, *i.e.*, a white with strong proclivities to pink, and neither the *Baroness Rothschild* nor *Marguerite de St. Amand* need fear this new "claimant" to supremacy.

Concerning *Rose trees* *al fresco*, I have not much to say at present, for the simple reason that I have stubbed up my *Rose* garden. Start not, my dear old floral friends! mourn not for me, dear Brothers of the Rose! my brain, believe me, is not more soft—my heart, I assure you, is not more hard, than heretofore. On the contrary, I know myself to be a wiser, truer gardener than I have been for years. Not only can I say, with the grand old King in the tragedy, "I am not mad," but I can thankfully congratulate myself on having just expelled from my system certain incipient symptoms of insanity. I have just thoroughly recovered from all indications of a tendency to that horrible mania, known to the profession as *Bedlaming*, I mean *Bedding out*. Consequently, I have to alter my garden, and for a time my *Rosery* is displaced.

But I still possess, in the place of vegetables, *i.e.* in my kitchen garden, certain consolations, in the form of 2,000 of the best *Briars* I ever had, budded last July, and *breaking* beautifully. From these I hope to derive shortly such happiness as only Rosarians know, and some information which may prove acceptable to those who read THE GARDEN.

S. REYNOLDS HOLE.

## NOTES OF THE WEEK.

— IT is announced that the People's Garden at Old Oak Common, Willesden, will be opened for the season, to members and their friends, this day.

— SERIOUS mischief has been done to the Vines in France by the frosts at the end of last week. The prospects of the champagne vintage, especially, are much imperilled.

— ALONG with the cleansing of the lake in Victoria Park, and its re-filling with water, many other improvements are in progress. A new concrete wall, with granite coping, has been erected around it. The islands which dot its surface have all been re-covered with turf, as have also the various surrounding slopes. Several fresh shrubberies have also been planted, and ornamental rockeries erected.

— MR. WM. PAUL's exhibition of Roses in the gardens of the Royal Horticultural Society, at South Kensington, commences to-day, and will be continued until Saturday next. In addition to Roses, of which there is a fine display, there are also other attractions in the shape of ornamental plants of other kinds well worth inspection.

— A GENTLEMAN has made an offer to the Westminster District Board, through his solicitors, to contribute £1,000 towards the cost of retaining as an open space the vacant land lying between Abingdon-street and the Thames, which the Government has the power of disposing of for building purposes. The District Board transmitted the communication to the Metropolitan Board of Works, and that Board has referred the matter to the consideration of a committee.

— EPIDENDRUM CNEPIDOPHORUM, a species introduced by the late Mr. Skinner from Guatemala, where it is found at an elevation of 8,000 feet, is now to be seen in great beauty at Messrs. Veitch's. It has stood in the corner of the Odontoglossum house for the last four years, has been rotted once, and is now producing, as it does annually, a great profusion of flowers. The flower-spikes are terminal, and somewhat globular in shape, about two and a half dozen flowers being on each spike; the blossoms are of a yellow colour, spotted with brown inside, but white tinged with lilac outside; the lip is pink and the throat white.

— A SECOND plant of the lovely *Odontoglossum vexillarium* is also now in flower at Messrs. Veitch's. That which bloomed first had blossoms resembling in shape those of a *Miltonia* or *Odontoglossum Phalænopsis*, but much larger, especially the lip, which was quite flat, and in colour they were delicate rosy lilac, without spot or stripe. The plant now in bloom bears two spikes on one bulb, and six flowers on each spike, and is quite a distinct variety from the one just alluded to. Its blossoms are of the same shape and waxy substance, but their colour is much darker, being, in fact, a deep violet peach, tinged with yellow in the centre, and conspicuously marked with three longitudinal violet lines—altogether a superb flower.

— PROFESSOR DU BREUIL last week recommenced his valuable course of public lectures on arboriculture in the municipal school of the Bois de Vincennes at Paris, in which he will discuss the best practical treatment of fruit trees during their period of growth. These lectures are free to all who choose to attend them, and the young gardeners of Paris, in thus obtaining first-class gratuitous instruction in at least one branch of their profession, possess an opportunity of self improvement which, we regret to reflect, is not open to their brethren in our own metropolis.

— AT the present moment, imported fruit of the Japanese Kaki are offered for sale in the shop windows of MM. Cuvillier, et frères, marchands de comestibles, 16, Rue de la Paix, Paris. They have been apparently dried and prepared in the same manner as our dried Figs and Raisins. The fruit, in their dried state, are 3 inches or more in length, and are described as having a firm and slightly gelatinous substance, of a reddish-brown colour, and sweet and agreeable to the taste. Many species of Kaki are cultivated in Japan, with fruit varying in dimensions from the size of a large fowl's egg to that of a man's fist. When fully ripe, they are said by M. Coignet to be dried in the sun and then preserved in flour, when they are equal to the best dried Figs. M. Carrière, however, states that, whether from habit or not, he prefers the Figs.

— IN Dr. Schomburgk's report on the Botanic Garden at Adelaide, a copy of which has just reached us, it is stated that "The manufacture of scents and essences is one of the most important. If we consider that British India and Europe consume annually about 150,000 gallons of handkerchief perfume alone, and that the revenue from imported perfumes in England is estimated at about £50,000, we may judge of the immense quantity of material used for perfumes. Most of the flowers which provide the material for perfumes grow luxuriantly with us—viz., Jasmine, Mignonette, Verbena, Rose, Lavender, Acacia Farnesiana, Heliotrope, Rosemary,

Peppermint, Violets, Oranges, &c. These plants thrive, probably, in greater perfection here than in any part of the world. No doubt South Australia should be a perfume-producing country, as we see here flourishing some of the most valuable scent plants. In proof of the value of perfumes, it may be stated that one acre of Jasmine will produce flowers to the value of £250 annually; Rose trees, £75; Orange trees, £50; Violets, £160; Cassia trees (*Acacia Farnesiana*), £90; Geranium plants (*Pelargonium odoratissimum*), £200; and Lavender, £30."

— ACCORDING to a communication by Professor Hallier, in the *Zeitschrift für Parisitenkunde*, a new Potato-disease made its appearance last autumn at Apolda, near Jena. In this new form of disease the fungus attacks the tuber at once, and not the leaves.

— OF the beautiful Brazilian *Colax jugosus* there are at present some nice plants in flower at Mr. William Bull's. The sepals are creamy white, petals and lip white striped and spotted with purplish violet. Mr. Bull has just received a large importation of *Odontoglossum coronarium*, and of other South American Orchids.

— OF *Vanda carulescens*, a rare and beautiful blue-flowered kind, a considerable importation from Burmah was sold the other day at Stevens'. A mass of it, consisting of eleven strong plants, realised £20. Of *Vanda Denissoniana*, another rare species from the same district, six plants fetched £11, and *Dendrobium thysiflorum*, a fine showy species, fetched £13 13s. The whole amount realised for 413 lots was a little over £889.

— THE magnificent collection of hardy Rhododendrons belonging to Messrs. J. Waterer & Sons, Bagshot, which, for the last twenty-three years, has proved so attractive at the Royal Botanic Gardens, Regent's Park, will this year be exhibited in Alexandra Park, Muswell Hill, where a large space is being covered for this purpose. From the appearance of the plants, the show promises to be one of the best of the kind ever seen.

— OF *Epidendrum bicomutum*, a recently imported plant is now in flower at Kew. The flower-spike, which proceeds from the top of the pseudo-bulb, bears five beautiful pure white blossoms, delicately spotted on the lip with violet, and tinged with yellow in the centre. This *Epidendrum* has been found somewhat difficult to flower, such plants of it as have blossomed being usually newly imported ones, in which the embryo flowers had been formed before importation.

— *CAMAROTIS PURPUREA* may now be seen at Messrs. Veitch's, bearing thirteen rosy purple *Aërides*-like clusters of flowers. Various ways have been tried to induce this plant to flower profusely, but none has answered so well as placing it on an erect wooden trellis in a pot filled with sphagnum and broken crocks. The roots creep around the woodwork, but seldom penetrate the contents of the pot, which, however, serves to keep the trellis steady. It enjoys the temperature of the *Cattleya* or East India house.

— FOR the opportunity of inspecting some handsome blooms and leaves of *Cyclamen vernum* we are indebted to Mr. Jas. Atkins, of Painswick, who has also furnished us with the following remarks respecting them:—"I send you," he says, "a few flowers and leaves of *Cyclamen repandum* of Sibthorp, *vernum* of most of the continental botanists, including Decandolle, Bertaloni, Reichenbach, &c., the *C. vernum* of L'Obel (1581), and *C. verno tempore flor.* of Clusius (1601). Both of the latter publish a very good figure of it from the same block. Those sent are from a common garden frame, in which they are turned out, and the whole of which is now one mass of beauty with them. It grows well with me out of doors in sheltered nooks, with perfect drainage and shade from mid-day sun." The flowers—which are of a beautiful rosy crimson, and the foliage, which is ample, and prettily marked with silver—of Mr. Atkins's plant are the finest and most luxuriant we have ever seen in any specimen of this *Cyclamen*.

— OF *Anthurium Scherzerianum* there are several varieties, some having broad leaves, others narrow ones, some arched leaves and others foliage almost erect. The flowers, too, of this fine stove-plant are as variable as the leaves, for we find among them long, narrow spathes, broad spathes, and others short and broad, almost approaching a circular form. In some, moreover, the spadix is scarcely curled, while in others there are two, and even three curls, but one striking characteristic is invariably present in all varieties, and that is the intensely brilliant scarlet colour. One of the very finest of the different varieties of this *Anthurium* is that called *A. Scherzerianum magnificum*, in the possession of Messrs. Osborn, the flower spathes of which are some 3½ inches in length and 2¼ inches in breadth, brilliant scarlet in colour, and with double, and in some cases even triple curled spadices. It is the parent of a numerous progeny, of which examples may now be seen in the Fulham nurseries, all having precisely the same characteristics as itself.

## THE FLOWER GARDEN.

### A ROCKY KNOLL IN OSMASTON GARDENS.

It is remarkable how a little peep or just a square yard or two of ground, with a few wild flowers, or other plants, in happy juxtaposition to a water margin or an old stone, often conveys to the mind an impression of sweetness connected with that particular spot never afterwards lost, and gives to it a character which for ever distinguishes it from all other places with which one is acquainted. All over England, and indeed, all over the world, such little spots often occur; in gardens they turn up in places in which one would least expect them, and as such features are everywhere so desirable, we hope from time to time to put before our readers little sketches of this description, the introduction of which into gardens is much needed. Gardens laid out to exhibit some one special scene only, as for instance a grand walk or terrace without a proper termination, are as disappointing as it is pleasant to find places in which, at unexpected corners, one comes upon little bits of scenery which have evidently emanated from minds and hands imbued with a true sense of the beautiful. The knoll of rock which we here figure was sketched at Osmaston Manor, and both it and its surroundings strikingly exhibit the taste and skill bestowed on this charming little bit of garden scenery; the Yuccas and their position, the little Ferns and Primroses, to say nothing of the lots of little things that could not be shown in a woodcut, the placing of the stones, the little Yews or Holly clinging to the largest one, the flowering Pampas Grass, even the very formation of the ground, rolling gently over in exact

Rocky Knoll in Osmaston Gardens.

agreement with the positions of the rocks—all these put together go to produce a feature more pleasing than many a flower garden, though it is limited in size. D

### OUTDOOR HYACINTHS.

WHAT becomes of old Hyacinth bulbs? Year after year thousands are imported, special exhibitions are held for them, and large sums are given in prizes for them; but what is the fate of the bulbs after they have once flowered? We are sometimes told that they may be used a second year for "dotting about" in shrubbery borders, but is it not a fact that, though grown by everyone, Hyacinths are hardly what one might call cultivated in England at all? Do they not come ready made to our hands from the Dutch growers? And this has led me sometimes to think that our horticultural societies might be a little less liberal in their prize lists to foreign raised Hyacinths, and might do something to encourage home-grown plants. For a year or two they would be poor no doubt; after which I believe our exhibitors would be able, if they took the matter fairly in hand, to beat the foreign bulbs.

My object in writing, however, is not to discuss the question of exhibiting, of which I have no practical knowledge, but to discredit the too generally received idea that the only place for Hyacinths after flowering is the rubbish-heap, and to plead for their more general use in the open garden; and I am led to do this by seeing with how little trouble a good show may be made with them. Mr. David Thomson, in his "Handy Book of the Flower Garden," tells us that "varieties suitable for outdoor

decoration can now be purchased so cheap that it is scarcely worth the trouble to save the bulbs;" and Mr. Fleming, in his "Spring and Winter Flower Gardening at Cliveden," says: "We have tried to renew the old bulbs, and also by well-prepared beds, to grow the offsets, but in both cases they are more expensive than purchasing fresh bulbs," and though this may be true, if we content ourselves with the unnamed bulbs sold cheaply by the hundred, yet I would advise owners of small gardens, at least, to buy good named varieties and to take care of them. I have now nearly 100 in flower, the spikes of which, if not fit for exhibition, are quite equal to the average of those used for conservatory decoration or sold in Covent Garden Market. These, with about twice as many smaller bulbs of various sizes (whose few bells by the way are often more useful as cut flowers than large spikes) are the produce of sixteen Hyacinths purchased in 1866, and twenty added in 1870.

Each set was grown in pots the first year (a loss of two years so far as increase of stock is concerned), and, after flowering, the bulbs were turned out of the pots into the open ground, without disturbing the roots, kept watered until the foliage began to look yellow, and afterwards taken up and dried. Subsequently they have been planted in the open ground, about the end of October in each year, at about 3 inches deep, and taken up when the bulbs were ripe. The soil of my garden is a sandy loam, with a subsoil of red sand, and consequently always free from standing water. I give a liberal supply of well-decayed stable manure and leaf-mould at planting time, digging the bed from 2 to 3 feet deep at least, and placing the manure near the bottom. Soot and lime are useful by way of a change, if the soil seems not to want more stable manure; and I have read, though I have not tried it, that salt is good. The main items as regards success seem to be a rich light soil, well drained and deep, that the roots may grow naturally—that is, straight down, for I believe want of depth for the roots is one of the reasons why the bulbs deteriorate under pot culture—care of the foliage until it dies down, and shallow planting, that the bulbs may ripen thoroughly. This they will not do until the end of June, but the summer planting of the beds need not be delayed on that account, as, if the leaves are carefully tied up, bedding plants may be put between them.

In old gardening books, elaborate instructions may be found for the cultivation of Hyacinths, but the directions for protection and shading are enough to frighten any one but an inveterate florist, and to make the garden unsightly if carried out. At the same time it must be admitted that shading considerably prolongs the time of flowering. Modern books seem to treat the subject after the manner of the quotations I have given. W.

### RAMONDIA PYRENAICA AND FRENCH CULTURE.

I BROUGHT back from Gavarni, about eight years ago, a fine specimen of this unique little plant, which I found growing in a small fissure on a large flat rock, without any apparent soil, and exposed to the full blaze of the sun. The position seemed to agree with it, as it had three stalks each, bearing a full quantity of blossoms. I attempted to imitate the site in which I found it in my garden, by planting it on a small heap of crocks, on which it lived and grew, but did not blossom. I have since then tried every variety of soil and culture, and although it has increased and been multiplied by means of offsets into many plants, none of them have ever yielded more than an odd blossom or two every two or three years. Terre de Bruyère, or heath mould, the French panacea for all delicate or fastidious plants, has no effect on it; indoors or out-of-doors, in pot or in the open ground, it is all the same, and until I read the article in No. 73 of THE GARDEN (see p. 277) I had concluded that it was naturally a shy bloomer. I should, therefore, be glad to know exactly how the plants at Benthall Hall are managed. Terre de Bruyère, which is nothing more or less than the *detritus* of heath on a sandy bottom, and consequently mingled with sand, is mostly found in forests and sometimes on sandy commons. The *detritus* of heath growing on bogs, although strictly speaking heath mould, is not "terre de Bruyère" in

the French acceptance of the term, and could never answer the purposes to which the latter is applied. In *terre de Bruyère* it may be said that all plants will live, although all may not exactly thrive; and the number of those that will thrive (especially the hard-wooded ones) is legion, while many cannot be got to grow in pots without it. The term "sandy loam," so often used by English writers on gardening, is a difficult one for French horticulturists to understand; if, for instance, we look out the word "Loam" in one of the last and best of English Dictionaries (Chambers', 1872), we find the definition to be "a muddy soil of clay, sand, lime, animal and vegetable matter." Now, whatever effect such a soil may have on a delicate potted plant in England, it would be pretty nearly poison to it here. Then again, if we look for the word "Peat," in explanation of peaty loam, we find it described as "a vegetable substance like turf, found in boggy places, and used as fuel;" in other words, what the Irish call "turf," and the French "tourbe." Now we know that here, as in Ireland, it takes a great deal of sand carting and bog burning to get even a stunted Scotch Fir to grow in it. Hence the impossibility of even attempting to follow here any British mode of pot culture as usually described, and the difficulty is generally solved by placing the new introduction, which almost always arrives through British importation, into plain *terre de Bruyère*; and not only that, but the English compost attached to it has often to be cleared away and replaced by *terre de Bruyère*, or the plant will linger on for awhile and finally die off.

FREDK. PALMER.

Versailles.

## NEW, RARE, OR NEGLECTED ALPINE PLANTS.

(Continued from p. 316.)

**LITHOSPERMUM GASTONI** (Gaston's Lithospermum).—A rare and beautiful species from the Pyrenees, with erect herbaceous stems about a foot high, which from May to August bear terminal clusters of large bright sky-blue flowers, about twice the size of those of *L. prostratum* (commonly sold under the erroneous name of *L. faticosum*). Leaves obovate lance-shaped. Grows freely on rock-work or in any open border in rich well-drained loam.

**LINUM VISCOSUM** (Viscid Linum).—A fine herbaceous species from the Pyrenees, with slightly branching downy stems from 1 foot to 1½ foot high. Blooms from May to August. Flowers nearly an inch across, of a rich rosy lilac colour, in an erect corymb. Leaves alternate, lance-shaped, covered with feeble whitish hairs and viscid glands. A fine subject for the rock-garden or choice border, in well-drained, moist, sandy loam.

**LINUM SALSOLOIDES** (Heath-like Linum).—A hardy, dwarf, half-shrubby species, somewhat like a dwarf Heath or Leschenaultia, with the stem twisted at the base. It grows from 3 to 6 inches high, and blooms in June and July, producing an abundance of flowers which are each an inch across, and white with a purple centre or eye. The leaves are linear, smooth, and scattered; the lower ones shorter and almost imbricated. A native of the south of Europe, this plant is not only well adapted for rockwork, but is also a very pretty object on the common border, in well drained sandy soil.

**MERTENSIA DAHURICA** (Dahurian Gromwell).—This plant, which was formerly known under the name of *Pulmonaria dahurica*, although of a very slender habit, and liable to be broken by high winds, is perfectly hardy, and was formerly often to be met with in British gardens. It grows from 6 inches to a foot high, with erect branching stems, which are angular and furrowed, and clothed with decumbent white hairs. It blooms in June, producing handsome bright azure-blue drooping flowers in racemose panicles. The leaves are ovate, roughish, slightly glaucous, and clothed with small decumbent hairs. It is a very pretty plant, and suited either for the rock-garden or borders, where it should be planted in a sheltered nook in a mixture of peat and loam. It is easily propagated by division or from seed.

**MITCHELLIA REPENS** (Variegated Partridge Berry).—This is one of the most interesting of the pretty woodland plants that accompany the Ground Laurel (*Epigaea*), the tree Lycopodium, the Rattlesnake Plantain (*Goodyera*), &c., in the Pine woods of North America. It is a smooth and trailing little

evergreen herb, with roundish shining leaves, and minute stipules. The flowers are white, sometimes tinged with purple, and bear pretty scarlet berries in autumn. I saw it in Long Island, running about in the Moss, &c., at the bottom of Pine trees, and it occurred to me at the time that it would be a charming addition to shady parts of our rock-gardens, hardy ferneries, &c., in which it would thrive under the same conditions as the *Pyrolas*, the *Linnaea*, &c. It is named after Dr. John Mitchell, an old Virginian botanist and correspondent of Linnæus.

**MUSCARI ARMENIACUM** (Armenian Grape Hyacinth).—A strikingly beautiful and scarce species, growing about 6 inches high and flowering in May, when it produces a dense spike of flowers of a fine cobalt-blue colour with three small yellow dots near the mouth of the corolla. The spike is 2½ inches or more in length, and the flowers are most agreeably fragrant. The leaves are about 9 inches long, ribbon-like, concave, and pointed. An exquisite plant for level spots on rock-work, for the bulb-garden, or for borders in light soil.

**MUSCARI HELDREICHI** (Greek Grape Hyacinth).—A beautiful, and as yet rare, kind from Greece about 14½ inches high, with flowers of a fine deep sky-blue with white mouth, somewhat like those of *M. botryoides*, but nearly twice as large, and arranged in a longer spike. Leaves about 4 inches long, flat, like those of *M. commutatum*, but not open at the top, like those of that species. A fine subject for the rock-garden or the choice border, in deep sandy soil. Comes into bloom in the end of March.

**ORCHIS FOLIOSA** (Leafy Orchis).—A very handsome and showy Orchis, found on rocky banks in the island of Madeira, and growing from 1½ to 2½ feet high. It flowers in May, when it produces a very great number of purplish flowers in a large ovate or oblong-ovate spike about 9 inches long and 3 inches across. The leaves are oblong, unspotted, the lower ones obtuse. May be grown in sheltered nooks in the rock-garden, or in the mixed border in deep light soil.

**OXALIS LASIANDRA** (Woolly-stamened Oxalis).—A singular and handsome Mexican species, growing from 9 to 18 inches high, and producing umbels of large crimson flowers in summer—about twenty flowers in each umbel. The leaves are all radical and digitate; the leaflets (7 to 9 in number) being 3 inches long and 1 inch broad, of an oval spoon-shape, dark green above, paler underneath, and spotted with crimson. It is a fine plant either for the rock-garden or borders, and should have a warm position in well-drained sandy soil.

**OPUNTIA RAFINESQUII** (Hardy Opuntia).—A dwarf spreading Cactus, forming clusters of thick, ovate, very green joints, each 3 or 4 inches long and about 3 inches broad, studded with small tufts of minute, sharp-pointed, reddish, hair-like spines. Flowers in summer, of a bright sulphur yellow. The fruit is said to be edible and "like a Gooseberry." North America. This *Opuntia* is a very free bloomer, and its dwarf, branching habit makes it better suited for out-of-door vase or rock-work culture than for a border. For several years past, the hardiness of *O. Rafinesquii* in the climate of London and Paris has been a subject of remark, and various persons in England and northern France have testified to its hardiness. The fact, however, that it stands and grows well in a London back-garden, deprived to a great extent of the sun, is as much proof as we need in that respect. This hardy species resists much greater cold than we ever have in Britain, and it is probable we shall find that half a dozen or more species of Cactus are quite as hardy. Along the line of the Pacific Railway, Cacti are abundant in some places—in districts frosty and silvered with snow when I passed over them in November, 1870, and on the flanks of the Wassatch Mountain, near Salt Lake City, deeply covered with snow during the winter. It is desirable, in gathering the small mountain plants there, and in sitting down on the ground, to look well for a small, poignantly prickly Cactus, with round stems, which abounds there, and which communicates a peculiarly acrid sting to all soft, fleshy parts that touch it. I gathered this in company with *Astragaluses* and other plants, which are usually termed alpine. In the northern States of America, which are very cold in winter, as everybody knows, there are three species of hardy *Opuntias*—*O. calycaris* (the common Prickly Pear), which goes as far north as New England; *O.*

*Rafinesquii*, in Wisconsin and Kentucky; and *O. missouriensis*, in Wisconsin and towards the great plains. And from what one sees along the Pacific route, it is very likely a greater number of Cacti go north along the Rocky Mountains' dry plains and sierras than we find on the eastern side of the continent. It is very probable we shall some day have quite a group of dwarf hardy Cacti keeping company with the Houseleeks on our rock-gardens, and rivalling them in hardiness. They should be planted on the drier parts of the rock-garden, on dry sunny banks, on the edges of old walls, old bridges, ruins, &c. They will also thrive on borders, but are most appropriately placed in the positions above named. Mr. James Atkins, of Painswick, informs me that he has grown a variety of *Opuntia vulgaris*, which he found in Piedmont, for upwards of 18 years without the slightest protection on the part of his rock-work which has a S.W. aspect.

(To be continued.)

### CAMPANULA TURBINATA ELEGANS.

AMONG dwarf Campanulas suitable for beds this is the most ornamental in the large and beautiful family of bell-flowers, forming, as it does, a compact leaf growth, and yielding from seed a mass of comparatively large, rich, purplish-blue, white, and porcelain-white flowers during the summer months. To have it in bloom the first season, it should be sown in the earliest spring months, and thus treated it will flower in the summer and autumn, or, if the plants bedded one season are again divided for planting in May, these will bloom effectively in the

*Campanula turbinata elegans.*

summer months, and, if sown in May, vigorous plants will be secured for the following year. *Campanula turbinata elegans*, sent out by Messrs. E. G. Henderson, is a hybrid between *C. turbinata* and *C. carpatica*, and it is greatly superior to both its parents as a decorative summer flower.

### PRIMROSES.

THESE are finer here than usual this season. Each plant is crowned with flowers, to the hiding almost of the tufted crowns of fine clean leaves. The Five-fingers, as they are commonly called here, or Cowslip-stemmed Primroses, are equally fine. The two together by the thousand make such a display of Primroses as I hardly ever remember to have seen. These common Primroses are better, in many respects, than all the uncommon varieties. They remind one of woods and groves, and sunny hedge-banks. Even the white and the orange have a garden character about them, which increases with every tint of colour, until we land amid Polyanthus and Auriculas. But for skirting woods and for infusing into pleasure grounds the sweetest breath of spring, commend me to the common Primroses. Doubtless we have room enough in our spring gardens for all possible varieties of Primrose; but I have some fear that, with our rage for novelties, we may discard our common varieties. This would be an irreparable loss to our gardens, too dearly purchased by the establishment of the Abyssinian or Japan Primrose in its stead. The former is fragrant almost as a Violet, and the latter pretty enough in its way; but neither have about them the simple beauty of our common Primroses, which, in masses, as decorative plants, are unequalled. It seems, too, almost a pity to mar the effect which

they produce by mixing them with anything else. Yet have I seen, on many a bank, Primroses made more attractive by being intermixed with early blossoms of the Veronica Chamædrys. Acting on this hint, the Primroses here have been pincushioned in various directions with *Myosotis dissitiflora* thrown in here and there. I have also observed how, when overhung with plants of *Ribes sanguineum*, the yellow Primroses seemed to become more yellow and more lovely on account of the contrast. Again, Primroses evidently like a wet season. To the excessive moisture of the late summer, the mildness as well as wetness of the past winter, I attribute their unusual richness and abundance this year. Even the double lilac, white, and others are fuller of flower and more robust in health than usual. Who has got a stock of the double yellow, red, and crimson, or port-wine colours of these grand old plants now? On the mixed borders, beside Daisies or early Heartsease and Violets, how beautiful these are, and how rich in old memories and home associations! How many of us seem at times to forget that, in floriculture, it is by no means necessary to be off with the old loves before we are on with the new; and even if that were the case, how many of us would still elect to be true to the old favourites that first bound our hearts to the gentle art, and, among these, how potent is the Primrose!

D. T. FISH.

### FLOWERS FOR THE MARKET.

THERE are a certain few early-blooming hardy plants of easy cultivation and effective when in flower, that I am astonished have not been ere now made useful and profitable for market purposes, as I am sure they would sell freely and by thousands if brought into Covent Garden. If a man were about to embark in the growth of these hardy plants he would require about an acre of good holding soil, a few hundred feet length of cold pits and frames, a roomy potting shed, a large stock of 60-sized pots, and plenty of fairly good soil with which to fill them. Then it would be necessary to secure and to work up as speedily as possible a stock of the plants to be operated upon, and having once done that I think it would be possible for a full tide of prosperity to set in upon him. The first, and possibly most beautiful plant among those that I would recommend is the early dwarf *Myosotis dissitiflora*, to secure a good stock of which it would be necessary to sow about an ounce of the seed as soon as it can be obtained after ripening, say early in July, either in boxes or in pans or in frames. With care and good seed, probably from 5,000 to 6,000 seedling plants would be obtained, and these would merely require, when large enough, to be pricked out in nice friable soil, about 4 inches apart each way, and to be kept well watered until they were thoroughly established. Early in November, a thousand or so should be lifted with small balls, potted, and then placed in frames close to the glass, letting them have all the air possible on dry days, and a little covering during frosty weather. Two or three other batches should also be lifted during the winter, so that a succession might be maintained; and if the first batch could have the advantage of a little extra warmth, or be taken into a greenhouse, they would be in full flower fit for market by the end of February, and possibly earlier. Some plants should be left for seed, as in no case should old propagated plants be trusted; they are not worth twopence for any purpose. This Forget-me-not grows in such neat little bunches, and is so beautiful, that it would become a universal favourite if people could purchase it cheaply and in abundance. Another charming plant, with which Londoners are as yet comparatively unfamiliar, is the golden-blotched double red Daisy, which, even out of flower, in the depth of winter, is a veritable gem. This plant would, I believe, sell either in or out of pots literally by thousands all through the winter, from November onwards. Persons who see it for the first time are enchanted with it, and whether seen under heavy rains or in pleasant sunshine it is alike charming. It can be propagated just as easily and as freely as the common double kinds. One plant, if it does well through the summer, will make ten or a dozen in October, and these, again, will grow into strong material by Christmas. As some stock would have to be retained, the smaller plants could be kept for that purpose. Some potted up and placed

under glass would fetch a good price. Then what beautiful things for pot work, if properly managed, are the double white and mauve-coloured Primroses! These must be kept fresh, green, and growing all through the summer, and be lifted and pulled to pieces about Michaelmas, the strongest being potted into 60-sized pots, and the remainder planted thickly in beds, so that they may be lifted as required. Five hundred plants of each of these planted out now would, with good cultivation and plenty of water in hot weather, make 5,000 of each colour next autumn, so that a large stock could soon be obtained, and thus, with diligence and care, the foundation might soon be laid of a good business. Other plants could also be introduced of a like character, but all should be hardy, and easily and cheaply grown. A. D.

**Rose and Clematis Covered Screen.**—I have erected a screen, so as to part a newly made croquet-ground from a fruit-garden. I purpose planting two Roses, one light and dark alternately, then a Clematis, then two Roses, to twine together and form an archway on the top. The screen is composed of sixteen rough Fir poles, 8 or 9 feet high, and what I want is the most suitable Roses and Clematises with which to cover it.—A. SUBSCRIBER. [Use free-growing sorts of evergreen and Ayrshire Roses, say the following: White: Felicité Perpetuelle, Rampante, Thoresbyana, and the Garland. Red: Boursault Amadis, Flora, Princess Maria, and Russelliana. The Clematises may consist of *Lanuginosa nivea*, white; Jackmanni, purple; Lady Bovill, puce; and Miss Bateman, white; Sieboldii, white; Lord Londesborough, violet; and the small-flowered kinds, *Flammula* and *Cærulea odorata*.]

**Aretia Vitaliana.**—This is a very beautiful but a most capricious plant. After many attempts at its cultivation with uncertain results, I have at last grown it satisfactorily in the open air, on a border composed of broken stones intermixed with a compost of sharp sand and loam, with a little peat. It grows freely when once established, and has a tendency to straggle and get "leggy," which soon results in the ends of the growing shoots dying off. I find the great secret of success is to keep the plant constantly "soiled up" with a little sharp sand, into which the young shoots freely root and form a round hard cushion. A plant I brought from Dauphiné in 1870 is now 8 or 10 inches in diameter, and is showing numbers of little yellow flower-buds. I have also flowered the plant freely in a cold frame, but it turned brown and died soon afterwards.—G. MAW, *Bentall Hall*.

**Transportation of Heath.**—In the ice-house with the salmon ova from England, arriving at Hobart Town in May 1866, two bundles of Heath and a few shrubs were sent, as an experiment, to try this plan of sending trees. Upon the arrival of the Lincolnshire these were sent over to Mr. Mitchell, of the Experimental Farm, who reported upon them as follows:—"The six Apple trees, and also the two species of Heath (*vulgaris* and *ciliaris*), three plants of each, sent out on the surface of the ice-bin along with the salmon ova, arrived here in the most perfect condition possible. Indeed there is not even a decayed leaflet on the Heaths, and the whole of the plants are in as perfect health as if they had only been lifted out of the nursery on the day they were handed over to me."

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Primula nivalis and P. helvetica alba.**—Mr. Ellacombe wishes to state, with reference to a note recently published in THE GARDEN, that these two plants are quite distinct. *P. helvetica alba* is the white form of *P. viscosa*, so common in the mountains and high valleys of Switzerland.

**Large-flowered Single Larkspur.**—Allow me to inform your "Nameless" correspondent (see p. 297), that I have for years possessed this plant, and that I consider it to be one of the best plants I have. It grows double the height of its variety, the double Siberian Larkspur, and is of a most intense ultramarine blue, with a rich metallic lustre. The name "grandiflora" conveys an erroneous idea of the size of the flower, which is only of medium size.—T. OS. WILLIAMS, *Both Lodge, Ormskirk*.

**Dormant Rose Buds Injured by Frost.**—Briars budded last year commenced growing in January and February, and many of the buds which had started into premature growth, owing to the then unseasonable weather, have been killed by the severe frosts which prevailed on the nights of the 22nd, 23rd, and 24th of February, varying from 19°, 27°, and 30° below freezing. In Yorkshire at the time I am writing (12 a.m., 24th April), snow is falling heavily, which has continued at intervals from 7 a.m. this morning, and the thermometer stands at 30°. Wind N.E., and very cold.—H. TAYLOR, *Encote, near Bedale*.

**The Creeping Fig hardy.**—This is grown in a small cool house in Mr. Ellacombe's garden, at Bitton, and through an opening in the roof a long shoot has passed up the wall of the dwelling house. It has not suffered in the least from cold. I have seen the plant thriving perfectly on an open garden wall in Colonel Tighe's garden, at Woodstock, Kilkenny. Many will, therefore, find a new use for it for outdoor Ferneries, rock-gardens, walls, &c.—R.

## THE INDOOR GARDEN.

### CLIANTHUS MAGNIFICUS.

THIS variety of the Glory Pea is, as its specific name implies, a truly magnificent and really charming plant, resembling its well-known congener, *Clianthus puniceus*. It appears to have been introduced into this country about the year 1830. Its flowers are large, and of a deep, rich scarlet colour, but without the dark, or rather black, boss which renders the blooms of *Clianthus Dampieri* so attractive; but, in all other respects, *Clianthus magnificus* is greatly superior to that species, as well as to *Clianthus puniceus*. The flowers are produced in immense pendulous bunches, and continue long in perfection; and, even when not in flower, the bright, shining foliage of the plant is exceedingly ornamental, and it does not, like the two other species named, become an easy prey to red spider or insect pests of any kind. It is nearly, if not quite, hardy, of rapid growth and easy cultivation, requiring abundance of room, and by no means particular as to soil. It will, indeed, luxuriate in any moderately rich compost, such as may be successfully used for the cultivation of the Pelargonium or the Fuchsia. For the purpose of clothing the back wall of a lean-to greenhouse, or for training to pillars, &c., in the conservatory, there are few plants that equal or surpass this fine *Clianthus*. A plant of it covers a large portion of the back wall of a greenhouse here, and is at the present time (April 10), and has been for the last three weeks, densely covered with hundreds of bunches of its large, rich, and singular-looking flowers.

*Colford, Bury St. Edmunds.*

P. G.

### CONSERVATORY CLIMBERS.

WELL-KEPT conservatories are often spoiled by unhealthy, shabby-looking climbers; whereas, when the climbers are healthy and well-flowered, they add so much to the good effect of a house, that they often redeem many shortcomings in the way of general furnishings. Climbers in an unhealthy, starved state, besides being unsightly, belie their true character, and they are, moreover, peculiarly the prey of insect life, especially of red spider and thrips. This unsatisfactory condition is generally the rule where climbers occupy pots or boxes, or are otherwise confined as to root space. To obviate this, in the case of such as are in narrow borders, I would recommend planting them in the open air, and introducing them through the front wall, the same as is done with Vines, allowing the more tender ones the south side, and the hardier sorts the other aspects. Many climbers, which are usually supposed to be too tender to stand out of doors, will be found to do well under this kind of treatment. The roots, though outside, need not necessarily be exposed to frost, but even of that not a few will stand several degrees. Care must, however, be taken to have them planted in a thoroughly well-drained position, and if the subsoil is not naturally gravel, a site must be prepared for them, in which a bottom is made of brickbats, lime rubbish, or some open material, and the roots must be protected in winter in the same way as those of early Vines. *Tecoma jasminoides* has grown here against a west wall for two years, and this last winter without any protection, while in the previous winter a mat only was used. *Rhynchospermum jasminoides* we have proved to stand 5° or 6° of frost, also *Mandevilla suaveolens*; but there is no necessity for exposing the top of any conservatory climber to frost, and the roots can also be easily protected. When planted outside, care must be taken not to have the necks of the plants exposed before entering the house; but where the walls are set on arches, planting inside, and, if the border is narrow, allowing the roots to run through to the outside, is best. We have, however, some here planted without any inside border at all, there being simply a hole in the wall, through which the stem of the climber is introduced. Thus managed, even *Taesonina Van Volxemii*, almost the graudest of all conservatory climbers, and a native of New Granada, succeeds perfectly. It flowers profusely all through the winter, and produces seed-pods as large as Gherkin Cucumbers, hanging by a thread. *Tecoma jasminoides*, which, under ordinary circumstances, has a tendency to grow to wood, treated in this way becomes almost

perpetual flowering, its showy umbels of Petunia-like flowers being much admired. *Mandevilla suaveolens*, too, the finest white-flowered conservatory climber with which I am acquainted, and which has a perfume almost equal to that of *Stephanotis*, flowered here up to November, and became almost deciduous, when it was pruned like a Vine, and now, in the middle of April, it is showing bloom again, and will soon be a sheet of white, trumpet-shaped flowers. The Glory Pea of New Zealand, *Clianthus magnificus*, and also *C. puniceus*, are well known to be both very accommodating plants, but liable to spider when grown indoors. These, treated as described, are, however, free from that pest. *C. Dampieri* may be inarched or grafted on the *C. puniceus*, a plan by which that ticklish creeper may be grown to perfection. I need scarcely mention such plants as *Passiflora cerulea* and its varieties; *Taesoniamanicata*, or *ignea*, and *mollissima*; the *Bignonias capreolata*,

a very dark brown. Its beauty, both as regards colour and habit, renders this species a grand object for window decoration during the warmer months of the year, and also for the ornamentation of halls, corridors, and porticos. Associated amongst other plants in a stove, too, it has a pleasing appearance, especially when elevated on an inverted pot, so that its head may be above the surrounding vegetation. This, like most of the coloured-leaved kinds, thrives best in a stove temperature, and on account of its comparatively dwarf habit it must not be overpotted. For our illustration of it we are indebted to Messrs. Veitch. A.

#### SPRING FLOWERING CLEMATISES.

THESE are less robust in growth and less hardy in constitution than the summer-blooming race, and, blooming as they do quite early,

*Dracena Dennisonii.*

radicans, and grandiflora; but of the brilliant *Bignonia venusta* I hope to be able to give a good account, planted out in this way. We also have *Passiflora Buchananii* planted in the way I have described; also *Lapageria rosea*, and various others, as well as plants not exactly climbers, such as *Luculia gratissima*. It will thus be seen that this is but carrying out, under particular circumstances, the modern idea of sub-tropical gardening, which has yet to be still further developed in many other useful ways. W. DICK.

Conford.

#### DRACENA DENNISONII.

THIS is another of the many fine species of this genus recently introduced from the South Sea Islands. It is a dwarf, robust growing kind, thickly furnished with leaves, which are about 15 inches long and 4 or 5 inches in breadth, their colour being

require house protection either in a cool greenhouse or conservatory. Unlike the summer-blooming Clematises, which produce their flowers on the wood of the current year's growth, the spring-blooming race produce theirs on the ripened wood of the previous year, and therefore in pruning them during the winter only the decaying wood should be cut away. The plants should be grown in pots or tuos, or planted out in the borders of a conservatory, but so placed that they can have space to spread out their ample growth. They can be grown in pots in a small conservatory, and trained to stakes in the form of pillars, or round wire trellises of globular shape. Pots from ten to twelve inches in diameter will be found quite large enough for the first and second year's growth, but afterwards a larger size will be required. All the Clematises require rich soil, such as a good free loam mingled with leaf soil and decomposed manure, and the soil should be at least 3 inches below the rim of the pots, so as to admit of the plants being mulched with manure during the time of flowering, and a little weak manure water may be given at times with advantage. The plants should be placed

in their blooming pots the previous spring, or not later than September the previous autumn; but there is a certain risk in potting late, as it frequently destroys the chance of flowers. It is therefore best to have the plants placed in their pots a year before the time of blooming. Treated in the way just suggested, many of these beautiful Clematises can be had in flower in March and April, and almost up to the time when the summer-blooming races display their flowers. Let it be distinctly understood that it is quite in the power of those having only a small conservatory attached to a suburban residence to grow a few of these Clematises in pots as suggested.

Mr. Noble, of Sunningdale, has produced some beautiful hybrids belonging to this class. They comprise Albert Victor, deep lavender, with brown ribs along the centre of each petal; Harry Richmond, lavender-grey, each petal having a flame of deep violet; Lord Londesborough, rich mauve, the petals having the centre stripe of maroon; Lady Londesborough, silver-grey, with flame of white; Mrs. Villiers Lister, cream tinted with pink, and bars of maroon; Mrs. Howard Vyse, white, each petal edged with mauve; Miss Bateman, pure white, very fine stout flowers; Princess Mary, pink, suffused with puce, each petal having a pale stripe; and Queen Guinevere, creamy white. Mr. Noble has other varieties, but the foregoing have been repeatedly shown, and therefore a definite opinion can be formed as to their merits. Other good varieties of the spring-flowering kinds are Azarea grandiflora (C. patens), delicate mauve lilac, with pale centre; Sophia, deep lilac purple; Standishii, light mauve; and Victor Lemoine, blue tinged with violet. There is also a class of double-flowering kinds which find favour with many; they consist of Sophia plena, lilac purple; Florida plena, creamy white; Fortunai, creamy white, large rosette-like flowers; and John Gould Veitch, lavender-blue, full double flowers. The old C. Sieboldii, with its freely-produced creamy white flowers, is also well worth cultivation. R. D.

## THE FRUIT GARDEN.

### PEAR CULTURE.

BY JOHN SCOTT.

(Concluded from page 319.)

WHILE recommending root-pruning, it is necessary that I should say a few words to prevent its being over-done. 1st. When a tree has attained the height of 6 to 7 feet, and is in a free growing and healthy condition, making a considerable quantity of wood every year, and not much fruit, it is then time to check its over-luxuriance by root-pruning. Now, this first cutting of the roots is a most important operation for the tree's welfare afterwards, and requires to be done with caution, that is, never cut any tree more than half-way round the first time: take out a trench half round, making the stem the centre of a circle, with a radius of 15 inches; mark the half circle, then take a good sharp spade and remove the earth, about 15 inches wide, outside your half circle, to the depth of 18 to 24 inches, cutting all the horizontal roots you find, and then pass the spade well in under the tap roots, for they are the cause of unfruitfulness; and it is of primary importance that they be well cut through. Having done this fill in the hole with some good half rotted manure, mixing it well with the earth as you fill up, keeping the best of it nearest to the surface. If this first cutting throws the tree into bearing, you will not require to repeat the operation on the other half until the tree again shows symptoms of over-luxuriance and an inclination not to produce its fruit; then is the time to serve the other half circle just as you served the first. Let your tree then rest until it again gets too luxuriant, which may either be in two, three, to six years. I need only say that root-pruning should cease whenever the object for which it has been used is attained; there is no use in root-pruning a fertile tree; besides, overdoing the thing causes your trees to produce dry, sticky and gritty fruit, therefore be judicious in the use you make of root-pruning. In most cases no tree requires more than two or three root-prunings, and these only at intervals, according to circumstances, as I have just shown. My specimen pyramid Pears are planted at 6 feet apart; they are seventeen years old, and are now pictures of fruitfulness, being covered from the top to the lowest branch with well developed fruit buds; and from having been regularly and well root-pruned, they hardly require a knife to be put upon them.

I have now given directions for raising pyramids from the commencement, but nothing is gained by so doing; time

is lost, and no money is saved, as the maiden trees will probably cost from 1s. to 1s. 6d. each, and a finely-formed root-pruned tree may be purchased from my nursery, from 5 to 6 feet high, at from 2s. 6d. to 3s. 6d.; a tree that would, if the season was favourable, produce half a peck of good fruit the second year. To those who have wet, heavy, or cold soils, I would say, plant Pears upon the Quince stock; to those with light or too warm soils I would say, be careful what Pears you plant: the sorts that do upon such soils are few, and care should be used in selecting those kinds that will do well, such as Beurré Hardy and Williams' d'Hiver, which will grow on the Quince in almost any soil. Trees grown on Quince stocks require little or no root-pruning; yet to be lifted occasionally, with all their roots intact, keep them in a fruitful and healthy state. Trees on this stock are improved by periodical lifting, and by covering their roots well in winter with half decayed stable manure. If attention be paid to plant the trees deep enough, so as to cover the junction of the graft, and to annual or biennial mulching, it is amazing what fine fruit will be obtained. The Quince roots do not run very deep, and, therefore, should have food at the surface. A piece of ground, say 36 feet square, would hold 36 trees, upon the Quince stock, set six feet apart each way. These could easily be manured annually, and would amply repay the care bestowed upon them; they would require but little pruning, and if a close hedge of Arbor vitæ were put around them it would protect them from storms, and in spring it would be very inexpensive to cover them all over with a thin hutting and thus insure an annual crop. This is what I call an orchard house for the million, and it can be carried out either on a small or large scale, according to the fancy of the planter. In strong moist clayey soils, the trees will require to be lifted oftener than on light or loamy soils. Bushes on this stock require only to be kept lower, by not allowing the leading shoot to grow, but distributing the branches so that they may form regular bushy heads, which must be kept regulated and thin, to admit air to all parts of the tree.

The cordon system is another useful way of training and growing Pears: this can only be practised where some kind of support is given to the trees, such as a wall, paling, stakes, or wires. The trees may be planted from 1 to 2 feet apart, if against a wall or paling, and trained to a single shoot; this is to be attached to the wall, either horizontally, obliquely, or vertically, and trained in full length; the side shoots will require to be pinched back once in summer to about 3 inches long, and early in winter cut back to one or two eyes: these, in many instances, will have become fruit buds in autumn, unless the tree has got its roots without bounds, which must be prevented by a free use of the spade, to stop them from penetrating too deep into the earth—a thing that causes more unfruitfulness, and more falling off and shanking of fruit, than all the diseases to which trees are subject. Do not over-pinch the shoots of your trees, as disease will be sure to follow, but rather cut away all straggling roots, and especially such as take a perpendicular direction. This root-pruning is a thousand times to be preferred to having a faggot or two cut from your trees every year. Do not be afraid to use a good sharp spade to cut your roots: a knife is useless; a man with a spade will effectually root-prune a tree in ten minutes, which, if left to grow unchecked, and to send its roots deep into the cold soil below, would take the same man an hour or two to properly prune it, and every year would increase the useless labour of cutting and backing the branches; added to which, you would be looking for fruit, and your tree would only produce you the usual annual amount of faggot wood. But let a clean sharp spade stop the liquid flow from below, and then look out for fertility, and keep your knife shut in your pocket—at least nearly so, *i.e.*, only use it to thin, stop, or regulate the branches, now become ropes of fruit spurs. The Gilogilles is, perhaps, the strongest growing of Pears: I had some splendid trees of it, annually making shoots from 6 to 8 feet long, and some of them one inch in diameter; but they produced no fruit—the knife only made things worse, but a few strokes of the spade soon altered their appearance. Early in August I cut the fangs that drew the supplies too abundantly from below; the following spring the tree was a sheet of bloom, and did not make a shoot 6 inches long for the next four years, but, instead, produced

quantities of large, round, russety fruits, some of them from half to three-quarters of a pound each. The same treatment holds good with all over-luxuriant trees: cut the branches only, and you will have annually to repeat the operation; cut the roots, and you will gather fruit instead of faggots. Hardly any tree is too old to be operated upon. By doing this the quantity, flavour, and quality of the fruit will be improved. But be careful, as I have said above, not to overdo the matter.

*Merriott, Crewkerne.*

#### CURE FOR BARKED FRUIT TREES.

SINCE the winter of 1867 and 1868, there has been none more favourable for field mice than the one just ended. Over a wide range of country the ground was covered with a heavy body of snow in December. This was added to by frequent storms, and it remained during the entire season. In closely-planted orchards the snow was piled in places several feet in thickness for eight or nine weeks, and afforded just the conditions most propitious for these active little pests. Trees from which the bark has been gnawed all around, and from 6 to 12 inches in width, are sure to die within a year unless prompt measures are taken to restore connection between the bark above and below the wound. The prescriptions for effecting this, which have been published from time to time, are as numerous as flies in midsummer, and most of them as unsatisfactory. Where only a third or a half of the circle has been made, leaving a connecting strip, then by covering the bare part with a coating of cow-droppings and yellow clay, the young bark will grow over the wound much sooner than if left exposed. Where there is no such connection,

Mode of curing Barked Trunks.

however, the best and most simple method of forming one—and the method that never fails—is to insert scions (one, two, or three, as the case may require), bridging over the barked part, as in the accompanying illustration, which is an exact drawing of a Pear tree that four years ago was barked, and (with many others similarly treated) is now in fine condition. The method is simple and rapid, and any one can effect the operation without difficulty. Take the scions of last year's growth of wood, from young healthy trees, cut them the right length, bevel each on the same side at both ends. Then, with a budding-knife, make an incision in the bark of the tree above and below the injured part, and carefully press the scion into position. Cover over where the incision was made with grafting-wax, and then wind around the stem of the tree, at both ends of the scions, some narrow strips of bast matting, which will keep them firmly in their place. For trees from which the bark has only been gnawed half or two-thirds the way round, one or two scions will be sufficient; but when there is no connection left, it will be found advisable, particularly on a large-sized tree, to put in three scions. The work may be done at any time between the 1st and 10th of April.—*New York Tribune.*

#### STRAWBERRIES OUT-OF-DOORS.

IN nineteen out of every twenty of the gardens of England Strawberries are not grown out-of-doors to the best advantage. In the first place, the ground is not well prepared previously to planting; in the second, the runners are not selected sufficiently early to obtain a crop of fruit the following season; and, lastly, the plants are allowed to remain on the same ground year after year, until only the merest apology for a crop is

obtained from them. Under good cultivation, the Strawberry will succeed in almost any description of soil, although a deep loam of a clayey nature suits it best. To very light soils, it is advantageous to add clayey loam if it can be readily obtained. The ground intended for the reception of the plants should be prepared by being trenched at least 20 inches deep, applying at the same time a good dressing of farm-yard manure. As Strawberries are frequently planted, a season is lost before a crop can be gathered; this ought not to be. A crop of Peas, Potatoes, Cabbages, or anything that can be taken from the ground before the second week in July, may be grown, and as soon as they are cleared off, the space intended for the Strawberries should be trenched, as the plants will succeed all the better if the ground has been prepared a few weeks previously. The runners must be prepared for planting as soon as they can be obtained, and in most seasons this will be about the first week in July. They should be layered in small pots, in a compost consisting of three parts loam to one of well-rotted manure, and each runner should be kept in its place by means of a small peg; some place a small stone on the tendril to keep the runner in position, but this does not hold it so securely as a peg does. In about a fortnight the most forward runners will be ready to be removed from the parent plants, when they may be cut away and placed in some open space until the later ones are ready, which will be in about a week or ten days. The ground by this time should be ready for their reception, as the sooner they are planted the more abundant will be the crop the following season. The rows should be 2 feet apart, and the same distance should be allowed between the plants. The operation of planting should be performed in a careful manner, and a shallow depression ought to be left around each plant, in order that they may be watered effectually should continued dry weather set in. Strawberries, especially on light soils, are liable to be attacked by red spider about planting time; and should the young plants be infested with this pest, it will be necessary to dip their leaves in a pail of water, in which a quarter of a pound of tobacco has been steeped, and in which the same quantity of soft soap has been dissolved; as, unless red-spider can be dislodged from the leaves, the plants will not grow freely. After the plants are put in the ground they will require no other attention that season except running the hoe between the rows to destroy incipient weeds. By these means a good crop of fruit may be secured the season after planting, and I may add that after many years' experience I have found it to be most advantageous to destroy the plants as soon as the fruit is gathered and sufficient runners can be obtained to plant a fresh bed for the following year's crops. I have repeatedly left the plants to bear a second crop and have compared them with those which were planted the previous year, and the result has been that, both in wet and dry seasons, the largest crops and best fruit have been invariably obtained from the young plants. This system of cultivation is also, I believe, the most profitable, inasmuch as no time is lost as regards cropping; for the ground, it will be remembered, was just cleared of an important crop of vegetables previously to its being trenched and well manured for the Strawberries. As soon as the old Strawberry plants are cleared off, which can be done readily by cutting them just underneath the surface with a spade, they may either be wheeled out to the vegetable heap, or burned on the ground; the space should be hoed over deeply with a draw hoe, and may be planted at once with white Broccoli, no other preparation being required. The same system of cultivation may be pursued year after year with the most satisfactory results.

As to varieties, the earliest to ripen is Black Prince, which is an abundant bearer, and when cultivated on the annual system its fruit is of fair average size, while that from old beds is not larger than good sized Marrowfat Peas. Keens' Seedling still maintains its character as being an excellent second early dessert Strawberry, and it makes an excellent preserve, of a rich dark colour. President is a grand sort for dessert, and seldom fails to bear a good crop. Premier is a very large-fruited kind, of a rich dark colour, and bears abundantly; though a desirable sort, it is only second-rate as regards flavour. Sir Charles Napier is an excellent variety for preserving. Its fruit is very large, of a bright red colour, and of

a sub-acid flavour, which is liked by some. British Queen, a fine old sort, of large size, is still the richest flavoured of all Strawberries. Frogmore Late Pine is undoubtedly the best of the late Pine-flavoured sorts. Its fruit is of large size, cone-shaped, and borne in profusion. Besides these, there are many more excellent varieties, but the kinds just named are sufficient even for very large establishments. J. D.

### THE CASTLE KENNEDY FIG.

EVERYONE who has seen and tasted this Fig in its true character will acknowledge its merits as regard size, appearance, and flavour. As regards size it is, I believe, the largest Fig grown; it has the reputation, however, of being a shy bearer, which is no doubt the case under certain treatment. It will not force for two or more crops, like the Brown Turkey, nor bear pinching well, though it is a very early Fig. The best samples of it I have seen have invariably been borne on the points of the last year's shoots; and I think Mr. Fowler has on several occasions exhibited samples of such shoots with numbers of fine fruit on them. I have tried it in various ways here, and find that the best and most profitable returns are secured by treating it for one crop only in the season. With this end in view, the pruning of the tree is a matter of some importance. I have heard of the Castle Kennedy Fig doing remarkably well in an orchard house where it was planted out in the border, judiciously root pruned, and allowed plenty of head room—perhaps the very best way of growing Figs of any variety, and especially those kinds that do not force well. The only pruning required under such circumstances would be the thinning out of the shoots occasionally where too crowded; the shoots which are retained to be allowed to grow as much as they liked, and on no account to be pinched. If root pruning is attended to, or what is better, if the roots of each tree are confined by brickwork to a given space, the wood will not be gross, but short-jointed and hard, with a crowd of embryo fruit on the point of each shoot by the end of autumn, all or nearly all of which will come to maturity the following summer, if the trees are not neglected as to watering. Figs can hardly have too much water when growing, when their rooting space is restricted. When the trees are trained against a wall, the same rules must be observed in the pruning, only taking care to cover the wall space from top to bottom with bearing wood. The fan system of training is as simple a plan as any, but the shoots must not be tied too closely to the wall or trellis; on the contrary, they should be left projecting a little, to allow some freedom to the large leaves. J. S. W.

**Keeping Lady Downe's Grapes till Midsummer.**—Mr. Tillery's note on bottling Grapes (see p. 273) reminds me of the Irish gentleman, who, when offered Asparagus rather late in the season, remarked that he "never ate Grass after the Pays were in." It is a creditable feat to keep late Grapes till the middle of June, as Mr. Tillery does, but I have never known any one who preferred such for dessert when they could get early Hamburgs or others; nor, for that part of it, early Strawberries. We begin gathering Strawberries daily by the end of March, after which I find the demand for our Lady Downe's Grapes abates very considerably; even now we have some good samples of that variety, which look as if they would keep for a long while, though they have been bottled since the end of February; but our early Grapes, which are being pushed on for the London season, will set them aside. As regards the cost of fuel in the production of early Grapes, it just amounts to this—West-end families will have Grapes during the season, and if they cannot have them grown at their own establishment, they will have to buy them, and pay both the producer and the seller at perhaps the rate of twenty-five shillings per pound; while, if they grow their own fruit, it will cost them less than a fifth of that price. In our early viney here, 30 feet long and 16 feet wide, we have at present 200 bunches of fruit approaching maturity, and I am quite certain that £20 would cover the cost of fuel and the working expenses incurred in their production. The house is an item of one man's charge, and the mixed coke and slack which we burn costs about ten shillings per ton.—J. SIMPSON, *Wortley*.

**Gooseberry Trees.**—I have noticed the Gooseberry trees in many of the gardens in this neighbourhood, and there appears to be a poor prospect as regards fruit. January was unusually warm, and the buds would soon have been into leaf had not a hard frost set in in February. On Sunday morning February 23rd, my thermometer registered 19° of frost; on February 24th, 27°; and again on the 25th the thermometer stood at 2°, making 39° of frost. Snow fell also on these days; the effect has been to kill the premature buds, and many of the branches are quite bare of both leaves and fruit.—H. TAYLOR, *Fencote, near Bedale*.

## THE ARBORETUM.

### THE DECIDUOUS CYPRESS.

(*TAXODIUM DISTICHUM*.)

THE lofty trees which form the genus *Taxodium* are mostly found in the rich swampy soil of Florida, and other southern States of North America. In these swamps, on whose deep miry soil a new layer of vegetable mould is every year deposited, the deciduous Cypress attains its utmost development. In what is termed the "Dismal Swamp" in Norfolk, Virginia, immense numbers of these Cypresses flourish along with the white Cedars. Their largest trunks are 120 feet in height, and from 25 to 40 feet in circumference above the conical base, which, at the surface of the earth, is always three or four times as large as the continued diameter of the bole. In felling them, the negroes are obliged to raise themselves upon scaffolds five or six feet from the ground, as the base is usually hollow for three-quarters of its bulk. Its surface is longitudinally furrowed with deep channels, whose ridges serve as cramps to fix the tree more firmly in the loose soil. The roots of the largest specimens, particularly of such as are most exposed to inundation, are covered with conical protuberances, commonly from 18 inches to over 4 feet high, and sometimes 4 or 5 feet in thickness. They are always hollow, smooth on the surface, and covered with a reddish bark like the roots, which they resemble, also, in the softness of their wood. They exhibit no sign of vegetation, and M. Michaux states that he has never succeeded in obtaining shoots by wounding their surface and covering

"Knees" of the Deciduous Cypress at Syon.

them with earth. No cause can be assigned for their existence; they are peculiar to this Cypress, and begin to appear when it is 20 or 25 feet in height; they are not made use of except by the negroes for bee-hives. In the park of Fontainebleau a number of these Cypresses are planted along the margin of a stream. These have produced such an abundance of protuberances as to form a sort of natural wall along the river bank, and for a distance of 30 or 40 feet into the meadow they are so numerous that it is impossible to mow the Grass with a scythe. The summit of this Cypress is not usually pyramidal, like the Spruces; but widely spread, and even upon old trees depressed. The foliage is open, light, and of a fresh agreeable tint; each leaf is 4 or 5 inches long, and consists of two parallel rows of leaflets upon a common stem. The leaflets are small, fine, and somewhat arching, with the convex side outwards. In the autumn they change from a light green to a dull red, and are shed soon afterwards. The deciduous Cypress has occasionally produced cones in this country, but such an occurrence is not very common. One of the largest specimens of this tree in England is to be seen in the grounds at Syon House, of which the annexed is an illustration, drawn and engraved for THE GARDEN. It measures 84 feet in height, 14 feet in circumference at 3 feet from the ground, and the diameter of the branches is 43 feet. Around the base may be seen the protuberances or "knees," as they are sometimes termed, appearing above the surface of the ground. In our smaller illustration, above, we have figured some of these "knees" separately, in order to give some idea of the aspect which they present individually, on a closer inspection.

DECIDUOUS CYPRESS IN THE PLEASURE GROUNDS AT SYON.—(SKETCHED APRIL 1873.)

PYRUS (CYDONIA) JAPONICA.

PLANTS of this *Pyrus* rank amongst the most beautiful of all our early flowering shrubs. I have seen them glow with a beauty on the walls of dwelling-houses such as the most brilliant Rose could hardly match. The flower-cups seemed full of glorious light as one looked into them, fully expanded and exposed above their scant foliage, that hugged the wall as closely as if it feared to hide a single bloom. Here and there throughout the country one stumbles upon a glorious plant of this *Pyrus* that sets one a-craving. Henceforth one or more are ordered. They come so stiff and stunted that they either die or make no progress for years, and hence, I believe, to a great extent, the reason that this grand old plant is not more generally cultivated. It is not popular. The demand does not create a supply, and when a few are wanted, old ground keepers are sent out that refuse to grow. This is unfortunate, for this is, indeed, a noble plant, and also a free-growing one in some localities. But it seems to suffer somewhat from weakness of constitution. Most plants have one or more stunted branches, on which the leaves have a good many shades—too many—of yellow in them, and these yellow-leaved branches are only too apt to die altogether. The plant is generally propagated by means of layers, and grown on its own roots. I think a fortune might be made out of grafted plants worked on other and freer-growing kinds of *Pyrus* or *Cratægus*. This *Pyrus* is mostly grown as a wall plant; but it forms a nice plant for the back or front of a warm shrubbery, or the back of a herbaceous border; and would look extremely rich and drossy as a standard, or on stocks that would feed and stimulate it into free growth. In this way it might prove a valuable plant for forcing, as I have seen it frequently in flower in the open ground in the beginning of April, and occasionally, on a south wall, in March. The branchlets of bloom would be admirable additions for the dressing of vases, and the single flowers would look well in bouquets surmounting white or Primrose flowers. There are several varieties of this fine old plant—the common Japonica or scarlet, carnea or a flesh-coloured kind, the pure white, and a semi-double red. The great points are healthy plants to start with, and a free growth, which, I think, would be assisted by free stocks. As it is, the plants are mostly all flower, and, in a majority of cases, more or less unhealthy.

D. T. FISH.

**The Shakespeare Oak.**—On the tercentenary of Shakespeare's birthday, nine years ago, Mr. Phelps, the tragedian, planted an Oak, from the Royal forest of Windsor, on the side of Primrose-hill next the Regent's Park. The young tree has flourished, in spite of a want of proper protection; and it is now thought that, to prevent further reproach, an ornamental iron palisade should be erected round the Oak, and that a characteristic tablet should also adorn the spot. Mr. G. Victor Morgan, F.S.A., of New Broad-street, is the honorary treasurer of a fund which has been started for this purpose; and the co-operation of actors, authors, artists, and the general public is invited to raise, by small subscriptions, a sum of about £200.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Tulip Tree.**—The largest specimen of this perhaps in England is at Corney, close to the Duke of Devonshire's at Chiswick.—A.

**The Douglas Oak.**—The *Quercus Douglasii*, of which mention was made last week, forms a large deciduous tree in California, with downy and sinuately lobed leaves from 3 to 4 inches in length. It was sent home by Hartwig in 1847, and is quite hardy in this country.—G. G.

**Planting Hollies.**—Will you kindly tell me in your next impression what you consider the best time for transplanting Holly trees? Those I have to transplant are of many years' growth, the stems near the bottom being about 12 or 13 inches in circumference.—H. A. [The best time for transplanting Hollies is in showery weather in May.]

**Zones of Conifers from the Mediterranean to the Crest of the Maritime Alps.**—The following table shows the lowest and highest elevations in feet at which the different species are found:—

	Lwst.	Hghst.		Lwst.	Hghst.

The starting points from the coast embraced the line from Monaco to Ventimiglia.—M. MCGERRIGER.

***Prunus obovatifolia*.**—A seedling of *Prunus spinosa*, raised by M. Carrière, and differing from the parent in being entirely devoid of thorns, and having broadly oboval leaves and larger flowers. The tree is very vigorous, with a remarkably straight stem and spreading branches, covered with a red and very shining bark. It first bore fruit in 1872, seven years from the time of sowing. M. Carrière is of opinion that our garden varieties of the Plum must have sprung from a stock similar to this, although the received notion is that our thornless Plum trees are merely one of the results of cultivation.

THE LIBRARY.

A LITERAL TRANSLATION OF THE ELOGUES AND GEORGICS OF VIRGIL.\*

THIS is a fairly good translation, based, as the author states in his preface, on the annotations of the late Professor Conington, whom he nevertheless, somewhat inconsistently as it appears to us, labours hard to depreciate. The entire preface is, in fact, one long attack on the Professor's renderings of numerous passages, as being either deficient in accuracy or wanting in felicity of expression. We do not ourselves agree with Mr. Wilkins in many of his observations, and we do not think his translation gains anything from the severity of his remarks on the work of the late Professor, which he admits was left in a very unfinished state. There is no doubt that Mr. Wilkins has not unsuccessfully (to use his own words), "attempted in some degree to echo the Virgilian rhythm," as will appear from the subjoined extracts from the second and fourth books of the *Georgics*, in which the cultivation of the Vine and the management of bees are treated of; and there is therefore the less reason why he should have thought it necessary to add to his reputation by a self-instituted and, we must say, invidious comparison of his own version with that of Professor Conington.

VIRGIL'S DESCRIPTION OF SPRING.

LET no counsellor have such credit for foresight as to induce you to stir the stiffened soil while Boreas breathes; winter then seals the land with frost; and when the plant is set, forbids it to strike home to earth its frozen root. The best season for planting Vineyards is when, amid the blush of vernal flowers, the white bird, the trailing serpent's deadly foe, has come, or on the verge of autumn's earliest chills, ere the sultry sun has reached the realm of winter with his steeds, and when summer is just passing away. Spring ministers to the foliage of the groves, spring to the woods: in springtime earth swells with fruitfulness, and asks the seed that giveth life. 'Tis then that the almighty father Air descends in fertilising showers into the lap of his joyous spouse, and in his might, mingling with her mighty frame, nourishes all the embryos within. Then pathless brakes with tuneful birds resound, and herds on certain days renew their loves; bounteous earth teems with life, and the fields open their bosoms to the zephyr's balmy breezes; a delicate moisture abounds everywhere; the herbage safely dares to trust itself to meet the newborn suns; nor does the Vine-leaf dread the rising of the southern gales, or the shower driven from the sky by the north's impetuous blast, but puts forth its buds and all its leaves unfolds. Such days as these, I would fain believe, shone at the primal hour of the infant world, and held the tenor of their birth; that was the reign of spring; it was springtime that the vast globe was enjoying, and the east winds forbore their wintry blasts, what time the first cattle drank the light, and man's race reared its head—a race of iron from a land of stone—and wild beasts were sent to range among the woods, stars amid the sky. Nor could tender nature long endure her trials here, did not a prolonged repose intervene between wintry chills and summer heat, and heaven's more genial mood relieve the earth.

A POOR MAN'S GARDEN IN VIRGIL'S TIME.

FOR I well remember seeing, beneath Cælia's lofty towers, where dark Galæus bathes the golden meads, an old man from Corycus, the owner of a few acres of unapportioned land, of a soil of no fertility for ploughing, unpropitious for grazing, ungenial to the wine-god's juice. Yet he, while planting pot-herbs here and there on thorny ground, with a border of white Lilics, Vervain, too, and tiny Poppy seeds, matched in the pride of his heart the wealth of kings, and returning home in the late evening hours would load his table with a feast unbought. He was the first to pluck the Roses of spring, the fruits of autumn, and while sullen winter was still splitting the very rocks with his frost, and bridling the flow of waters with his icy curb, he was just gathering the delicate Hyacinth's flower, chiding summer's slow approach and the zephyr's long delay.

THE postal authorities urgently recommend the use of strong envelopes, which, in case of bulky or heavy letters, should be made of linen. This caution has become the more necessary since, owing to the late reduction in the rate of postage, many more bulky and heavy letters and packets are sent through the post than formerly.

\* A Literal Translation of the *Elogues* and *Georgics* of Virgil, by H. Musgrave Wilkins, M.A. London: Longmans, Green, and Co. 1873.

## THE KITCHEN GARDEN.

### ASPARAGUS.

(*ASPARAGUS OFFICINALIS*.)

THIS plant belongs to the Lily family, and is a member of a large genus of plants, mostly natives of Africa, distinguished by fine small leaves, which make some of the kinds very graceful and elegant. The common kind is a native of sandy shores all round the basin of the Mediterranean, and along those of western Europe, till it reaches the western and south-western shores of England. It also grows on sandy plains in South Europe and North Africa. The flowers, which are small, are greenish-white, borne in twos or threes, and are succeeded by small, round, red berries, and the plant has a very elegant and feathery habit.

SOIL, MANURE, &c.

Soils, subsoils, and situations differ, and so must practice also. The soil all round our sea-coast, if rich and within a taste of the briny, is eminently suitable for Asparagus; and once properly planted, it might go on for half a century without any more assistance than it gets from the flooding of each spring tide. Change the scene. Place the beds in Sherwood Forest, with 10 to 20 feet of drift sand underneath them, and, without the liberal use of the manure cart, in seven years you would not have a piece of Asparagus as thick as a pipe-stem. For good and lasting beds of Asparagus, considerable depth of soil is requisite. The best soil is a rich friable loam; but good crops may be obtained from any good sandy or mellow loam. Should the texture of the soil be too close, it should be sufficiently lightened and made porous by the application of large quantities of manure; sand or sandy mud is, however, more beneficial than manure in its opening qualities for heavy soils. The situation for this vegetable should be open to the sun, yet sheltered from strong winds. As Asparagus is one of the most permanent and lasting of all garden crops, and well-made beds continue in a good bearing condition for twenty years or more, it is advisable to decide, before forming the plantation, whether or not any alterations are likely to be made that would in any way disturb the beds. The ground should be trenched to the depth of 3 feet, at the same time turning in a heavy dressing of manure and seaweed (should the latter be easily obtained, otherwise it would not be advisable to go to the expense of procuring it, as very good Asparagus can be obtained without it); and should the ground be deficient in depth or quality, some good sweet loam from an old pasture may most advantageously be employed. These ought to be thoroughly incorporated with the soil at the time of trenching, and so worked that it may have an enriching and ameliorating influence on every particle of soil in the beds. This trenching should be performed in the beginning of winter, and laid up in the common way of ridging, thus to remain till spring; when, towards the end of March or first week of April, according to the state of the weather and condition of the ground, the ridges may be levelled, choosing for the operation a fine dry day. Fork and tumble over with a strong fork or pickaxe the ridges at all times when frozen hard, in order to pulverize, sweeten, and incorporate all well together. The principle of success with this vegetable lies within a small compass. All seem to acknowledge that, in order to obtain a good crop, there must be a good depth of rich soil. About forty years ago a good piece of ground was chosen to make a permanent plantation of Asparagus. It was trenched 3 feet deep in 3 feet wide trenches, and cast up into rough ridges, after a crop of summer Peas. All decaying vegetation in the rubbish-yards and corners was at the same time well salted and turned up. Early in autumn, also, were added some old Mushroom, Melon, and Cucumber-bed material, a lot of manure from piggeries, cow-houses, and stables, a quantity of road-grit and sand, a quantity of ditch and drain parings, turfy loam and sods, quite 3 feet thick—were all turned over four times and well incorporated together, between Michaelmas and Lady Day, as one would a dung-heap, the whole being left in large ridges exposed to the frost. By April this compost was in a kindly state; it was, therefore, laid down and planted with good, clean, one-year-old Asparagus plants, which certainly grew in a most extraordinary way, and the second year produced wonderful shoots as to size; and the same plantation

has continued to produce fine heads ever since. In order to give a fair idea of the quality of "grass" which this plantation is still producing, it may be mentioned that one hundred heads cut from it now average from 12 lbs. to 14 lbs. weight, the heads being 7 inches in length. Even after forty years' existence, this plantation is still improving, and it looks as if it would be as good sixty years hence as it is now.

Wherever ordinary farm-yard manure is not very abundant and labour plentiful, a good result may be obtained by collecting together all decomposing vegetable matter—old hotbeds, Mushroom beds, pig refuse, &c., with seaweed where convenient; and, when the position for the beds is determined upon, this should be spread upon the ground about a foot thick, and turned over with 2 or 3 feet of the earth two or three times in winter. This treatment will be attended with very excellent results.

The application of salt as a top dressing is of great benefit to Asparagus in inland districts, but is of little or no value in the vicinity of salt water. It should be applied in spring and very early summer by scattering some common coarse salt over the ground in showery weather. Old and well-established plantations are particularly benefited by this treatment; but in no case should it be applied to plants recently removed, for all such, however carefully transplanted, must have wounded roots, to which salt would prove very injurious; nor should it be applied at any time when the roots are in a dormant state. Besides its beneficial effects upon the plant as a manure, it is very destructive to the wire-worm and other insects so injurious to the roots of the Asparagus. Salt may safely be applied at the rate of 2 lbs. per square yard. It is, however, better to give this quantity in two doses. I have always found salt most beneficial. It should not be applied in dry or sunny weather.

SEED SOWING.

Asparagus is propagated by seed, which may either be sown when ripe in October, or in spring; but the latter time is certainly the best. It may either be sown on the ground prepared for the plantation, or in drills one foot apart in beds of light, rich, sandy soil, and transplanted to a permanent position when one year old, which is by far the most desirable method. To get strong clean plants at one year old, and to save a year's strength, sow thin, and hoe out quickly after the plants are up, with a sharp one-hand 3-inch hoe, or otherwise thin the plants to 3 or 4 inches apart, taking care to select all the strongest plants to stand; thus, very strong clean plants may be produced in one year. By keeping the seed beds carefully hoed and free from weeds, the plants will be in fine condition for planting out the following spring; whereas, should they be neglected, it will take two years before they are as large as well-attended one-year-old plants. It is in consequence of this very common neglect that many cultivators labour under the impression that the plants must be two or three years old before planting; which is undoubtedly a mistake, for all good growers invariably plant one-year-old plants, and count on reaping a crop the third spring from the time of sowing. One pound of seed will produce about 3,000 plants, and to plant an acre of Asparagus requires from 15,000 to 20,000 plants. Some of the finest shoots which push in the early part of the season from certain crowns should be allowed to run to seed. These should have the full benefit of exposure to light and air; and, as they advance in growth, they must be firmly staked, to prevent breakage by wind. When fully ripe, the largest and finest berries, of the deepest red colour, should be selected. They should then be carefully and gradually dried; or they may, after lying about ten days, be squeezed between the hands, and the pulp washed away; but by the former method they keep the longest.

PLANTING.

This should not be done till after the buds begin to push, as this plant, from its peculiar succulent roots, is less susceptible of injury from late planting than most other vegetables; yet it should not be delayed too long after the ground has become fit for its reception, in the end of April, as the sooner it is planted the better will be the result. Plant in rows 2 feet apart, 16 inches being left between the plants in the row. Planting in rows in preference to beds is to be commended, for by so doing the plants are allowed room enough to develop

their roots without interlacing each other, and consequently causing an impoverishment of the soil. After being planted two years, every alternate row is best taken up for forcing, thus leaving the permanent rows 4 feet from centre to centre. The direction of the rows for the main crops is immaterial, but for the earliest ones it would be advisable to run them east and west, so as to be more immediately under the direct action of the sun's rays when they are most powerful. As soon as the Asparagus has commenced to shoot an inch or two, level the ground down methodically, mark out the rows 2 feet apart, placing a stake at each end, where the rows are to be planted; stretch and place the line tight from end to end, draw a deep drill with the hoe on each side of the line, thus leaving a little ridge under the line, over which the planter should regulate the roots of the plants on each side, putting in the earth to cover them quickly as he proceeds. The hoe should be regularly used during the remaining summer and autumn months, care being taken to remove by the hand all weeds that come up about the crowns. When the stalks are completely withered in autumn, they should be cut down. Should the produce in spring be required in a green state, which is decidedly the best, an annual dressing of good manure slightly forked in should be given every autumn after the haulm has been cut, and thus left during the winter. In spring, before the buds begin to push, the ground should be again slightly forked over three or four times in dry weather, in order to lighten, pulverise, sweeten, and lay it down in an open healthy state, and not in too fine a condition, to get run together again immediately after the first heavy rains, but open, loose, and rather rough, in order to admit the sun's rays, atmospheric influence, and the rain kindly; such treatment not only forwards its progress, but also allows it to grow freely, clean, and straight without obstruction. I never use the rake for this purpose.

#### AGE OF PLANTS FOR TRANSPLANTING.

For planting, cleanly-grown and sound two-year-old plants are very generally preferred, although strong one-year-old plants are equally good. The balance of evidence is, indeed, in favour of well-grown one-year-old plants. The following curious experiment by a trustworthy French cultivator deserves consideration. (I have, however, repeatedly planted two and three-year-old plants, with perfect success, and even successfully moved a plantation nearly twenty years old.)

"I planted (No. 1) twelve roots of a year old; (No. 2), twelve of two years old; and (No. 3) twelve of three years old. The results were as follows:—

"First Year.—Of No. 1 all had made growth before May 1th, and the vegetation was fine; No. 2, ten plants started before May 4th, one on the 10th, and the other failed. The shoots were a little stronger than those of No. 1. No. 3, eight plants started before May 1th, one on May 12th, and the other three failed; and, although at first the shoots looked well, they afterwards declined, and on September 15th they were feebler than those of No. 2.

"Second Year.—No. 1, fine vegetation; shoots strong and regular on the 15th of September. No. 2, good growth; shoots irregular, and a little feebler than those of No. 1. No. 3, growth mediocre; shoots very irregular, some roots having eight or ten, but all feeble; another plant died after having produced two stems.

"Third Year.—No. 1, growth magnificent; stems measuring on the 10th of May from 2 inches to 3½ inches in circumference. No. 2, growth passable, but irregular; some tufts small and weak; the finest had shoots on the 10th of May, not more than 2½ inches in circumference. No. 3, growth very middling and irregular; some tufts gave off shoots no bigger than quills, and the best reached little beyond 1½ inch in circumference.

"Fourth Year.—No. 1, growth remarkable; the shoots appeared from the 3rd to the 10th of April, some as much as 4 inches in circumference; they afforded fifty shoots, which formed a bunch weighing more than 6½ lbs. No. 2, growth passable, but a little later than that of No. 1, and with plenty of small shoots; fifty made a half bunch, weighing little more than the half of that cut from No. 1. No. 3, vegetation poor, one plant not starting till the 22nd of April; fifty shoots formed only half a bunch, and did not weigh more than 2½ lbs.

"To resume, it will have been seen that the plantation formed with plants a year old gave at its fourth starting, or at

the end of three years of plantation, a bunch of Asparagus twice as large as that of either of the others. In other terms, the plantation made with plants a year old produced double that of the one where two-year-old plants were used, and nearly treble that made with plants of three years old."

JAS. BARNES.

## SOILS, MANURES, &c.

### SOILS FOR POT PLANTS.

LOAMS are of various kinds, and are strong or light as they may be taken from heavy or sandy soils. For plant cultivation, if the choice can be had, the best comes from the sandstone formation, strong loam being procured from the valleys, and light from upland situations. Loam, when it is possible, should always be procured from very old pastures, and is valuable or not as it contains much or little fibre. Some loams may be skimmed from the face of a rock not more than 3 inches deep, and so full of fibre as, when laid up for a few months, to form a most admirable compost. Loam should always be taken with the Grass on, and the shorter and closer the turf, as from an old sheep walk, the better the soil. Such loam should be cut to the depth of the close fibre—say 2, 3, or 4 inches, but not deeper. Loam which bears rough, coarse Grass is never good for the finer purposes of cultivation, though it may do for ordinary purposes, such as border making and the like. Indeed, it may be laid down as a rule that the more healthy the soil, the finer the plants that will be produced from it. The soil being selected, cut the turves as directed, and cart them home and stack them immediately. In doing this we should have three different stacks; one of strong loam, another of light loam, and a third of half-and-half, and the last double the size of the others, as it would be the most called upon. Loam should be collected when in a state of medium dryness; in fact, just in the state to promote slow decomposition when laid together, but nothing more. It is always best that the vegetative power of all perennial roots and weed seed also should be destroyed before the loam is used for plant potting; but this cannot be effected without subjecting it to considerable heat, more than can be commanded by simple decomposition. In such cases the process of burning may be resorted to, and it is thus effected:—A quantity of wood, such as Pea-sticks, prunings, and the like, being collected, it is built into a conical heap, the same as for burning charcoal, placing the kindling material in the centre, with a flue-hole at the bottom to get to it, and a thick stake to form a chimney through the centre of the cone. Then the turves are built up a foot or 18 inches thick, placing some small brushwood among them as the work proceeds. The stack being completed, light the fire, giving it vent by loosening if not withdrawing the stake altogether, and leading the fire to other parts by making vent-holes where it does not seem to burn freely. The fire fairly lighted, cover the heap a foot or more thick with litter or rubbish of any kind to keep the heat in, and by the time it has burnt out you have a mass of soil not at all charred, but the greater part of it heated to a sufficient temperature to destroy the roots of weeds or any seeds that may be contained in it, and the soil will also be considerably enriched by the process. Leaf-mould I never use, except for soft-wooded plants, and then I either collect it from accumulations in the woods, or prepare it especially. The latter is the best plan, when there is convenience for doing it. The plan is to litter well-fed horses in loose boxes with the leaves of Beech or Chestnut, avoiding those of the Oak as much as possible, because of the tannin they contain, and allow them to accumulate until they get too hot for the feet of the horses. In this way, and by throwing the sides into the middle occasionally, they get impregnated with urine and the more solid portions of the excrement, and when thoroughly decomposed, as the fermenting mass will be in a few months, form the finest manure imaginable for pot purposes, with the advantage that it will have been sufficiently heated to destroy every trace of weed seed, or insect ova—always a nuisance in natural leaf-soil. A portion of leaf-soil so prepared will be found admirable for admixture with loam, for soft-wooded plants of all kinds. Finally, soils, after they are procured, should either be placed in an open shed where the air can act freely upon them, or the stacks should be covered separately, so as to ensure the soil being protected from drenching rain. Nothing tends so much to the vigorous growth of plants as free healthy soils, and these can only be had by proper preparation at the proper time. Good soils are those of a soft unctuous quality, which work smoothly in the hand, as compared with harsh stubborn soils. Get soil of that quality at the proper time, and success is pretty certain to crown well-directed efforts at superior cultivation.

W. P. A.

## THE GARDEN IN THE HOUSE.

## COAT FLOWERS.

THESE I like associated with fronds of Maiden-hair Ferns, that is if the Fern is an indoor one; as what, for instance, looks so elegant with a Gardenia as a bit of Fern, the bright green spray of which sets off white blossoms of all kinds to much advantage. The coat flower to which was awarded the second prize at Birmingham last year consisted of a small spray of red Combretum, backed with a frond of Maiden-hair. There are numbers of flowers suitable for such an arrangement as this, but care should be taken that such as are selected are good specimens of their respective kinds, and be a little

Coat flower (small yellow Rose).

shrouded in the Fern, as many coat flowers I have seen were quite spoiled by having only one spray of Fern, against which was laid the flower; the latter, under such circumstances, looking hard and stiff. Now, had there been another small piece to fill up the space at the base, and a tiny bit drawn across the flower, the effect would have been much enhanced. This should always be done if the flower used is of a bright or glaring colour. The coat flower represented in the accompanying illustration is a bloom of a yellow Rose, arranged in this way. I always like to see a Rose with a leaf belonging to

Wired Rose-leaf (back view).

itself behind it, and a few sprays of the young brown coloured growth around it. Such an arrangement may seem easy to manage, but this is not the case, as the Rose leaf must be wired, and that is one of the most difficult of all things to do properly. Take a Rose-leaf, and lay it face downwards on a table. It will then represent a stem with two or three small leaflets on each side, and one at the top. Down the centre of each of these small leaves or leaflets is a comparatively thick midrib, with slighter ones branching off from it. Take a piece of fine wire and pass it through the leaf (always selecting the top

leaflet first), under one of these slight ribs, and bring it up on the opposite side of the ribs. Subject two or three of the ribs to this operation, always keeping close to the centre rib: in fact, work as if you were sewing through the leaf, having the long stitches, if I may so call them, on the wrong side, and it will be found to take great care and practice to keep them from being seen on the right side. The wire should be cut off at the top, so as not to let it appear above the point of the leaf. The other part should then be drawn down the long stem, and given a twist here and there; but take care to keep the wire from being visible. The little side leaves should be done in the same manner, the only difference being that the wire is cut off at each end, and not brought down the long stem like the top one. To do all this well takes some little time and trouble; but a Rose leaf, if not mounted as just described, is liable to get out of shape, and to hang down; if wired, however, it keeps stiff, and can be bent back and arranged according to fancy, just as one would adjust an artificial leaf. A. H.

## PUBLIC DINNER TABLE DECORATION.

THE most striking change noticeable in London for some time past has been the marked increase of the button-hole flower and bouquet trade. Half-a-dozen years ago such bouquets were to be had only in a few places; now shops full of them are seen in all our leading thoroughfares, and even hawkers in the streets sell tastefully arranged tiny bouquets. At the same time public taste has shown much improvement as regards table decorations and other indoor floral ornaments. Hitherto, so far as we have seen, the floral decorations of public dinner-tables have been poor and stiff in the extreme. At a dinner given the other night at the Inns of Court Hotel, more than the beauty of a dozen flower-gardens was tastefully arranged in the great hall of the hotel. Thousands of flowers and plants were employed, and these all in the freshest health. In addition to the best flowers and plants usually employed for table decoration, such novelties as superb pitchers of various kinds of Nepenthes depended from some of the vases, but the charm of the whole consisted in the tasteful artistic arrangement. No stiff, poor, flat, or round-headed compositions were these; but free and graceful as nature itself. All the principal varieties of Nepenthes were used, as well as the long trumpet-shaped Sarracenias judiciously arranged with Adiantum Farleyense, and here and there glowing spathe of Anthurium Scherzerianum, long and graceful fronds of various Ferns, large spikes of *Dielis spectabilis*, and the pretty curving fronds of Solomon's Seal. The glass vases were about 18 inches high, and the size of each group of flowers when arranged would be about 2 feet 6 inches across the widest part; these were set at intervals along the tables, and between them were placed "Dobson" dishes. These were filled in pairs to match with white, pink, and scarlet; the upper portion of the dish was scarlet Geranium, with crowning masses of Geranium Christine resting on *Lycopodium denticulatum*. The lower part or base of each stand had its bed of *Lycopodium*, with here and there magnificent blooms of *Maréchal Niel* and other grand Roses, interspersed with Lilies of the Valley. The whole of the dessert dishes were surrounded with glass circles filled with *Lycopodium* and fine trusses of scarlet Geranium Leonidas, one of the finest; the old favourite Dr. Ludley; Madame Vaucher, white, and the pretty Christine, pink. Mr. Wills considers these three colours the most effective for dinner-table decoration, and seldom uses any other colours. He pays upwards of £400 annually for the cut blooms of these three varieties, and upwards of £700 a year for *Lycopodium denticulatum*. His weekly consumption of this simple plant is over 300 dozen during the London season. The whole of the floral decorations were supplied by Mr. Wills.

**Azalea indica.**—This plant, with its many fine varieties, will bloom in winter, if cultivated in a double window, and even in a heated room. When grown in a room where the temperature is kept above freezing point, specimens with well-developed flower buds may be brought into bloom early by being removed into a warm room. The best kinds for this purpose are the white-flowered *A. indica alba* (or *A. ledifolia*) and *A. amena*, but many of the other kinds will also succeed treated in this way.

## WALL GARDENING.

It is not without considerable observation of the capabilities of walls, even walls in good repair, to grow numerous rare and pretty plants, and moreover keep them in perpetual health without trouble, that we call attention to the subject. Most of those who are blessed with gardens have usually a little wall surface at their disposal, and to all such we can name some plants that will grow thereon better than in the best soil. A mossy old wall, or an old ruin, would afford us a position for many dwarf rock plants, which no specially prepared situation could rival; but even on straight and well-preserved walls we can establish some little beauties, which year after year will abundantly repay the tasteful cultivator for the slight trouble of planting or sowing them. Those who have observed the way dwarf plants grow on the tops of mountains, or on elevated stony ground, must have seen in what arid positions many grow perfectly healthy—tufts springing from an almost imperceptible chink on an arid rock or boulder. They are often stunted and diminutive in such positions, but always more floriferous and long-lived than when grown fat and large upon the ground; in fact, their beauty is often intensified by starvation and aridity. Now, numbers of alpine plants perish if planted in the ordinary soil of our gardens, and many do so where much pains is taken to attend to their wants. This results from moisture at the root in winter, the plant being rendered more susceptible of injury by our moist green winters inducing it to make a lingering growth. But it is an interesting and useful fact that, by placing many of these delicate plants where their roots can secure a comparatively dry and well-drained medium, they remain in perfect health. Our attention was first called to the great adaptability of walls, ruins, &c., for growing many choice rock plants while visiting Dublin a few years ago. Near Lucan, we observed the upper portion of the old inclosing brick wall of a garden—indeed, all of it that was out of convenient reach—covered with a dwarf, green, mossy-like plant, and before coming close to it we asked the gardener what it was that made the wall so green. "It is," he replied, "a plant like a moss; but every spring it is covered with the most 'beauteiful' flowers." And, "sure enough," this is its character, for it proved to be the pretty little *Erinus alpinus*, which would have little or no chance of existing on the level ground in the same place, and which had, in the old days of cultivating rock plants, escaped by seed on to the wall, and there found a home as congenial as its native one. This will suggest at once that many plants from latitudes a little further south than our own, and from alpine regions, may find on walls, rocks, and ruins, that dwarf, ripe, sturdy growth, stony firmness of root medium, and dryness in winter, which go to form the very conditions that will grow them in a climate entirely different from their own. There are many alpine plants now usually seen cultivated in frames, even in places where there is a fine collection and much knowledge of alpine plants, that the most unpractised reader may grow in such positions as we indicate.

We proceed next to point out these plants, merely requesting the reader not to ask if what we advise is practised in gardens growing collections of alpine, but to put it to the test of experiment. The idea of growing such splendid alpine plants as the true *Saxifraga longifolia* of the Pyrenees on the straight surface of a wall, has never even entered into the heads of our botanists, who have in the public gardens the largest collections of these plants, and probably some of them would laugh at it; but we affirm that it is in the power of any person to succeed with them, and the trial can be made at a mere nominal cost. Generally, the best way to establish them is by seed. The Cheddar Pink, for example, grows on walls at Oxford, much better than we have ever known it do on rock-work or on the level ground, where indeed it soon goes off; a few seeds of this plant, sown in a mossy or earthy chink, or even covered with dust of any fine soil that be might be at hand, would soon take root and grow into neat little specimens, living, moreover, for years in that dwarf and perfectly healthy state so agreeable to the eye. So it is with most of these plants: the seedling roots vigorously into the chinks, and gets a hold which it rarely relaxes. Only the other day it was stated that *Myosotis dissitiflora* had taken possession of a wall in this manner. A few seeds of it had probably been dropped in some of the crevices by birds; there they grew and formed tufts of bloom that were the admiration of everybody. But of some things seeds are not to be had, and therefore it will be often necessary to use plants. In all cases young plants should be selected, and, as they will have been used to growing in fertile ground, or good soil in pots, and have all their little feeding roots compactly gathered up near the surface, they must be placed in a chink with a little moist soil, which will enable them to exist until they have struck root into the interstices of the wall. In this way we have seen several interesting species of Ferns established, and also the silvery *Saxifrages*; and we can assure the reader that the appearance of the starry rosettes of these little rock plants (we mean the kinds with the crustated leaves, like *longifolia*, *ligulata*, &c.) growing flat against the wall, will prove

strikingly beautiful. The most suitable kinds in the following list are marked with \*.

<i>Acerena Nova Zelandica</i> (mossy walls)	* <i>Dianthus cæsius</i> deltoides monspessulanus petrensis	<i>Saxifraga Hostii</i> *intacta ligulata *longifolia pectinata pulchella retusa Rhet *rosularis Rochelliana sarmatosa
<i>Achillea aurea</i> *tomentosa	* <i>Draba aizoides</i> * <i>Erinus alpinus</i>	<i>Schivereckia podolica</i>
<i>Adiantum Capillus Venæris</i> (on moist warm walls)	<i>Erodium romanum</i> (old walls) Richardii	<i>Sedum acre</i> * <i>acre variegatum</i> Aizoon *album *anglicum arenarium brevifolium *californicum cæruleum *dasyphyllum elegans Ewersii *farinosum globiferum Heuffeli *hirtum hispanicum *kamsclaticum montanum multiceps *piliferum pulchrum sempervivoides
<i>Alyssum montanum saxatile</i> (tops of old walls and ruins) spinosum	Gypsophila muralis (old walls and ruins) prostrata	* <i>Sempervivum araricoidem</i> sibiricum sparium *sexangulare scidum *tectorum
<i>Antennaria minima</i> (mossy chinks, with a little soil)	* <i>Helianthemum</i> (many of the varieties might be grown upon old ruins, stony banks, &c.)	<i>Silene acaulis</i> (moist walls, to be first carefully planted in a chink) *thestrus (old walls) rupestris Schefta (old walls and ruins)
<i>Antirrhinum rupestre</i> *majus Orontium	<i>Hutchinsia petraea</i> * <i>Iberis</i> (all the varieties, on old ruins, &c.) * <i>Ionopsidium acule</i>	<i>Symphandra pendula</i> <i>Thlaspi alpestre</i> (ruins, &c.)
* <i>Arenaria balearica cespitosa</i> ciliata graminifolia (old walls) montana (ruins) *verua	<i>Iris germanica</i> (some of the Irises of the germanica type we have seen growing freely on the top of earth walls, in thatch, &c.)	<i>Thymus citriodorus</i> (earthy chinks) * <i>Friehomanes</i> , and vars. viridis
* <i>Arabis albidia</i> (ruins and old walls) arenosa blepharophylla (old mossy walls) Incidia variegata petraea (old mossy wall)	<i>Koniga maritima</i> (ruins) * <i>Linaria Cymbalaria</i> Cymbalaria alba lusitanicus vulgaris	<i>Tunica Saxifraga Umbilicus chrysanthus Veronica fruticulosa</i> *saxatilis <i>Vesicaria urticulata</i> (ruins, &c.)
<i>Asperula Cynanchica</i>	<i>Linum alpinum</i> (old walls and ruins)	
* <i>Asplenium Adiantum nigrum</i> fontanum germanicum lanceolatum Rota muraria *septentrionale	* <i>Lycnis alpina</i> Flos Jovis (old walls and ruins) Iapponica Malva campanulata (ruins)	
<i>Astragalus monspessulanus</i> (ruins and old walls)	<i>Ononis alba</i> (old walls and ruins)	
<i>Bellum bellidioides</i> crassifolium *minutum	<i>Petrocallis pyrenaica</i> (mossy old walls, and rather moist position) hectica (north side of old walls)	
<i>Campanula Barrelieri</i> *rotundifolia *fragilis fragilis lanuginosa *gargauica pumila pumila alba	<i>Polypodium vulgare</i> and varieties	
<i>Centranthus ruber ruber albus ruber coccineus</i> Ceterach officinarum <i>Chiranthus alpinus</i> *Cherri Cherri pleno	* <i>Reseda odorata</i> (sown in chinks in walls, this sometimes becomes perennial, and looks very pretty drooping)	
* <i>Coronilla minima varia</i> (old walls and ruins)	<i>Sagina procumbens pleno</i> * <i>Santolina lanata</i> * <i>Saponaria corymboides</i> (old walls)	
* <i>Corydalis lutea</i> (a fine wall plant, even high on walls in warmer countries than this)	<i>Saxifraga bryoides</i> caryophyllata cæsia *crustata cænta-formis dipensioides	
* <i>Cotyledon Umbilicus</i>		

## THE GARDENER'S SONG.

The Gardener's is the oldest  
And the noblest craft as well;  
It was the only work thought fit  
For man before he fell.  
And though the first of brotherhoods  
Our own we masons call,  
That "grand old gardener," Adam, were  
The apron first of all.  
And so we'll sing the gardener's song,  
For that's the best of trades,  
And the King of Trumps in our esteem  
Shall be the King of Spades.

The Gardener is the richest man,  
For all he has he tills;  
His *stocks* are always rising,  
His banks he always fills.  
When other folks are saving,  
He may go it without stint;  
He never can be short of cash,  
For he always has the *Mint*.  
And so we will sing, &c.

The gardener's lot is freest  
From sorrow or disease,  
His *pitse* is always healthy,  
He never wants *Heart's-ease*.  
And beauty blushes where he goes,  
With smiles which never dim;  
And *Love-lies-bleeding* at his feet,  
And two-lips glow for him.  
And so we'll sing, &c.

## GARDEN DESTROYERS.

## CRIOCERIS MERDIGERA.

THE leaf represented in the accompanying woodcut is that of a Lily, which has been partially devoured by the larva of a small beetle, called *Crioceris merdigera*, which is pale red above and black below, and is very fond of the leaves of all kinds of Lilies, and more especially of the Crown Imperial. The beetle is figured on the leaf as twice its natural size. On the same leaf the reader will also see two darker masses—one in the middle, in front of the beetle, and the other a little behind it, towards the right hand edge of the leaf. These dark lumps are intended to represent, not the larva, but all that one sees of the larva. They are greenish, gluey-looking pellets, under which the larva is hidden, and consist of its excrement, which, by a curious provision of nature, is made to fall upon its back, and cover it as with a mantle. The reason is, that the larva has a transparent and very delicate skin, which cannot stand exposure to the sun and air. Such exposure would speedily destroy it, and to meet the emergency nature has given it a turned-up and slightly reversed tail, so that its droppings, instead of falling behind it, fall forwards on the back, and, by the contraction of its segments, each successive accretion shoves on the previous accumulation, until the whole back is covered, and when at last it falls, it is over the head instead of behind the tail. If this covering is removed from its back, the little creature begins eating with great avidity, as if it knew the best means of reclothing itself, and in a couple of hours it will be again covered. In other respects the larva is very lazy, moves very little, and only thinks of changing its place when the leaf has been a good deal injured.

The perfect insect passes the winter in the pupa state in the ground, from which it emerges in May. It then pairs, and little congregations of them may be seen at that time on the Lily leaves so engaged. The female then lays her eggs. These she deposits in little heaps, containing five or six eggs, on the underside of the leaf. It takes about a fortnight to hatch the eggs, and when the young larvæ come out they settle themselves to feed on the leaf in company. They may be seen arranged in little lines thus occupied until after the first change of skin. Then they separate, and each goes its own way, and they are then found scattered feeding both above and below the leaf. The larvæ do not take long to attain their full development. In about a fortnight they descend to the ground, and, burying themselves in it, they there pass into the pupa state, in which they remain for a similar period. In fact it is curious that each stage of its life seems to occupy about the same length of time—the eggs take a fortnight to hatch, the larva a fortnight to grow, the pupa a fortnight to rest; then the perfect insect comes out, unless it is in autumn. In that case the pupa remains in the ground all the winter, and the perfect insect only comes out next spring.

This insect is so conspicuous, whether in the perfect state or in its larval disguise, that it is not difficult to keep it within bounds. It is as easily caught as seen, and a little care in looking after them, seizing them, and destroying them, will suffice to do so. The garden must be badly kept where they are abundant, and although they may seldom do much actual harm to the bulbs, the gnawed leaves covered with dirt or dirt-bearing larvæ so disfigures the plants that they ought never to be allowed to establish themselves.

A. M.

Beetle-eaten Lily-leaf.

**The Bullfinch.**—Your correspondent, Mr. R. Gilbert, is in error as regards the bullfinch; it is not protected by law, but, though a notorious evil doer, I think it would be well to spare it at this time of the year, as the birds are nesting, and will soon have young; so by destroying the old birds those in the nest will be left to die a lingering death from starvation. There is no law in force at this season for the bullfinch but that of humanity, therefore, for humanity's sake, spare the old birds. I have nothing but this to urge in its favour for mitigation of punishment. I consider it does more injury to the garden and orchard than any bird with which I am acquainted. This year bullfinches are more than usually numerous and bold. In Keat, where my garden is, out of some hundreds of Plum, Gooseberry, and also flowering shrubs, I shall have no show, from the bloom-buds being eaten out by these bloom-bud eating birds, and in some instances my trees and bushes are utterly spoiled. To give some idea of the quantity of this garden pest I may mention that a neighbour of mine shot one hundred and seventy in one week, and still they were about our trees in packs of from forty to sixty. I see by the *Field* that in various parts of England they have been seen in equally large flocks. I protect the birds generally on my ground, especially starlings, thrushes, larks, linnets, and chaffinches; blackbirds I endeavour to keep down somewhat, but bullfinches I think have no good quality, and I do not wish to have one about, instead of which this year there are great numbers. Where have they come from?—HARRISON WEIR.

**Maggots in Oranges.**—Can you, or any of your correspondents inform me whether Oranges have been known to contain maggots? I opened an Orange a short time ago, apparently a good one to look at, and found a little nest of small live maggots. The rest of the fruit, where there were no maggots, tasted much like any other Orange, only rather flat.—RUSSELLITE. [The maggot to which our correspondent refers is too familiar in Orange-growing countries. The first notice we find of it is by Latreille, in Cuvier's "Règne Animal," vol. v., p. 534, who observes that the planters in the Isle of France cannot procure sound, ripe Oranges, on account of the excessive numbers of a small dipterous insect of the genus *Tephritis*, which lays its eggs on the fruit. M. Cattoire, then Paymaster of the Forces in the Mauritius, subsequently said that this little fly laid its eggs "in the ovary of the blossom"; but Mr. Mackay, who first described the fly, under the name of *Ceratitis citriperda*, in the *Zoological Journal* for 1829, agrees with Latreille that the egg is laid on the fruit itself. "As for St. Michael Oranges," he says, "towards the end of the season, namely, during the months of March, April, and May, whole chests are destroyed by this fly, specimens of which are easily procured, as they may be bred from the larvæ, which are to be found in almost every one of those damaged Oranges which our barrow-women display for sale in the month of May." It is a very curious and unexpected fact—we say unexpected because of the great difference of the two fruits concerned—that this fly has migrated in England from imported Oranges to indigenous Pears, and has done considerable injury to them. The life-history of the insect, with a very excellent figure of the fly, are given in No. 61 of the *Entomologist*, by Mr. Newman. We recommend our correspondent to procure this pamphlet. He will find the information on the subject full and interesting. It is published by Simpkin, Marshall, & Co., at 6d.—E. J. Field.]

A CORRESPONDENT of the *Gartenflora* calls attention to the mischief done by bees in flower gardens. Besides hybridising plants which it may be desired to keep true to name, he adds that, when certain tubular flowers (as those of *Salvias*, &c.), are so narrow that the bees cannot enter them, they gnaw a hole at the base of the flower in order to get at the nectary, and, in doing this, often injure the ovary so much, that the fructification is destroyed. *Salvia macrantha* (patens) in particular, he states, is hardly ever found to seed where bees have access to it.

## NOTES AND QUESTIONS ON GARDEN DESTROYERS.

**Ants.**—I have a house of Melons just setting, and being greatly troubled by ants eating the pollen, my foreman adopted the following plan of getting rid of them. He shot two or three birds, and merely running the knife down each side of their breasts, laid them on the soil as traps. In this way we catch them by the thousand, and being prepared with water to shake them into, speedily destroy them.—R. GILBERT, *Burghey*.

**Small Snails Found Among Tan.**—Will you kindly tell me the name of the enclosed, and also how to destroy them? They infest the tan in which our pot Vines are plunged.—E. H. W. [The pretty little snails sent herewith are *Zua lubrica*. They are very common under stems and among fallen leaves in both moist and dry places in all parts of the British Isles. They ascend to considerable elevation among mountains, and have a very wide range throughout Europe. We see no occasion for destroying such beautiful little objects, more especially as they are not recorded to have done any injury. The shell is figured in Forbes' and Hanley's, plate cxxv., fig. 8, and the animal, plate ggg., fig. 5, also in "Gray's Manual of Land and Fresh-water Shells," plate vi., fig. 65.—E. N.]

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**Conservatories.**—In these the finer kinds of Rhododendrons are now in great beauty, and none more so than the Sikkim, waxy, crimson-flowered *R. Thomsonii*. Some which have started into growth, and are planted out, must be well supplied with water; all decaying flowers and seed-pods should also be removed from them, unless it be desired to save seed, and even in that case only a few heads should be left on each plant. Azaleas done flowering remove from the conservatory, and repot; but if the plants are large, they may remain in pots of a given size for some years, without being disturbed. In that case, however, give a little manure-water during the growing season. Camellias, Acacias, Myrtles, Aracarias, Eugénias, and similar plants put out in beds and borders are now growing freely, and consequently require extra attention in the way of watering. Keep up a succession of blooming plants from other houses and pits; many stove plants and Orchids, indeed, may be transferred to the conservatory while in flower, and if they are placed in the warmest part of it, they will continue longer in beauty than if left in warm houses; after flowering, they should be replaced in their former quarters. Pot on plants of double *Petunia*, using light sandy loam and well-decayed manure for the purpose. *Mimulus* in conservatories are very ornamental, and used in that way a strong rich moist soil and cool position suits them best. Lemon-scented *Verbenas* also make good conservatory plants, as do likewise well grown and well-flowered *Heliotropes*.

**Greenhouse Plants.**—*Pelargoniums* now coming finely into bloom will be benefited by occasional applications of weak manure water. *Herbaceous Calceolarias* should now be finally and neatly staked, kept near the glass in a cool house, and also assisted with a little weak manure water. Stop, stake, and tie *Fuchsias*, keeping the winter-struck ones in rather warm and moist quarters, and permitting the old cut back stumps to come into flower in a cool house. Keep *Coleuses* in a warm house, placed here and there amongst dwarf plants on inverted pots, so as to raise them up to the light. Keep *Balsams* regularly shifted; as a rule, pots 6 or 8 inches in diameter are quite large enough for them. If from growing plants the flower-buds are pinched off, a late display of bloom will be the result. Pot on *Cockscombs* into 6-inch pots, and sow some seed for a successional supply of them. Of *Hydrangeas* introduce a few more plants in heat, and repot cuttings put in when the old plants were cut down. Sow annuals in succession, and pinch out the tops of such as *Rhodanthe Manglesii*. Pot Musk for conservatory use; and fill up wire baskets with *Isolepis gracilis*, *Asystasias*, *Tradescantias*, Musk, *Panicum variegatum*, *Achimenes*, Ferns, *Selaginellas*, &c. By keeping such baskets for a time in a warm, moist atmosphere, and afterwards gradually hardening them off, an effective display is soon attained.

**Frames.**—These will now be mostly occupied with bedding plants, which should be freely exposed whenever the weather is favourable. Keep the plants also as far apart as space will permit. *Hyacinths*, *Tulips*, *Crocuses*, *Narcissi*, &c., done blooming, should now be kept in frames, and gradually dried off as soon as their bulbs are ripe. *Cinerarias* that have flowered may be cut back and placed in frames. When they have pushed up suckers, select the best of them, and pot them singly in 60-sized pots, which may also be kept in a cold frame. *Antirrhinums*, stored in pots during the winter, may be planted out as soon as the weather has become warmer; let any required for flowering indoors be repotted and have their shoots pinched back. Strike cuttings of *Phloxes*, and transfer specimen plants of them to their flowering pots. Keep *Pansies* in frames having a north aspect, thin out their shoots, and use the thinnings as cuttings. *Anniculas* done blooming should be kept in a cool, airy frame, protected from rain.

**Hardy Fruit Garden.**—Pay particular attention to the protection of the blossoms of fruit trees on walls. Thin out *Apricot* fruits a little where they grow in clusters, but leave considerably more than an ordinary crop undisturbed until the stoning period has been passed. Disbudding of *Peach* and *Nectarine* trees must soon receive attention; strong growths on vigorous shoots must be well reduced, whereas the weaker ones should be sparingly dealt with, so as to preserve an equilibrium in the tree. Insects of all kinds must now be looked after, the curling of the leaves indicating their presence. Green fly will now be troublesome, but the use of the syringe or garden engine is very destructive to them; tobacco-water, in which a little soft-soap and sulphur has been mixed, is very efficacious in removing them. Pear trees are everywhere now in full bloom; but Apples, as a rule, are still comparatively dormant. The only exceptions are such early sorts as the *Oslin* and *Early Peach*, which are already opening their bloom-buds.

**Kitchen Garden.**—Make up deficiencies from seed beds, and hoe between lines of young plants in order to kill weeds and promote

growth. As soon as seedlings are fairly up, whether they are in beds or rows, they should be weeded and thinned. Thin out *Cabbage* plants, and transplant the strongest as soon as they are fit to handle and ground is prepared for them. Transplant *Canliflowers* sown in frames in February and sow seeds for early autumn use. Plant out *Brussels Sprouts* for early crops, and sow some *Savoy*s for late use. *Asparagus* may yet be safely transplanted; plantations made, indeed, in the first fortnight in May thrive quite as well as those put in earlier. Sow some *Borecole* to succeed the *Potato* crop. Sow a few *Cardoons* in rows where they are to remain; seedlings of them raised in frames should be gradually hardened off before they are consigned to the open garden. Thin *Carrots* a little, but not too much at first, as a second thinning should be the final one. Winter *Spinach*, when done with, should be destroyed, the ground manured and dug, and held in readiness for *Cabbages* or for *Cauliflowers*. Prepare trenches for early *Celery* 4 feet apart; market growers make theirs 5 feet apart. A good admixture of rotten cow or horse manure should be incorporated with the soil in the bottom of the trenches. Transplant *Basil* from frames to the open air in warm positions; *Bush Basil* being the hardier, though the smaller, of the two, is the kind most commonly used, yet common *Basil* is also frequently grown. Transplant knotted *Marjoram* from frames to a warm border or quarters. Of the small-rooted *Beets* (which are usually the best) make another sowing if necessary, and thin out those first sown. Keep plants of *New Zealand Spinach* still in cold frames, but gradually harden them off, so as to prepare them for transplantation at the end of the month. Of *Mesembryanthemum tricolor*, the leaves of which are so useful for garnishing, prick off those sown last month into boxes, and thence to well-sheltered positions in the open ground towards the end of the month. Earth up *Potatoes*, and keep the hoe at work amongst them. Sow successions of the white *Paris Cos* and *Neapolitan Cabbage Lettuces*. Transplant those from earlier sowings as they become fit to handle and ground becomes vacant for them, and with a piece of matting tie around the middle the most advanced plants of the early sowings, in order to cause them to heart properly. Sow *French Beans* in succession—the dwarfest sort 18 inches apart, the *Newington Wonder* and *Negro* 2 feet apart, and the red and white *Runner Beans* in rows 4 feet asunder. The intervening spaces may be cropped with *Spinach*, *Lettuces*, or any other quick-growing crop; and between the rows of late crops *Brussels Sprouts* may be planted. Transplant *Leeks* from frames and early sowings; and, if necessary, sow a few seeds for a late crop. Harden off *Tomatoes*, as they will be required to be planted out in a week or two if the weather continues mild. Top a row or two of the earliest *Peas* when they come into bloom, so as to induce them to form pods sooner than they otherwise would do. Plant out *Vegetable Marrows* under handlights. A barrowful of fermenting manure placed under each plant greatly assists their growth. Make successional sowings of *Spinach*, *Radishes*, *Mustard*, *Cress*, *Rape*, and a few other small crops.

## MARKET GARDENS.

Owing to the continuance of ungenial weather, *Cucumbers* planted out in frames must be well protected with litter, especially at night. Plant out *Vegetable Marrows* under handlights, in rows about 12 feet apart, and 6 feet plant from plant in the row; under each plant should be a barrowful of fermenting manure. Be careful to cover around the base of the handlights with stable litter, which must also be thrown over them at night. Between the rows half-a-dozen lines of *Cos Lettuces* may be planted, as they will be removed before the *Vegetable Marrows* grow sufficiently strong to encroach upon them. *Tomatoes* should be pricked off singly into 4 or 6-inch pots, which should be planted in cold frames, and kept rather close for a time; but afterwards gradually exposed, so as to thoroughly harden off the plants before planting-out time. Still protect *French Beans* grown in frames or under other sheltering material, such as hoops and mats, but admit plenty of fresh air, unless it be cold or frosty. Sow another crop for succession. Keep the hoe at work amongst crops of *Lettuces*, *Canliflowers*, *Cabbages*, young *Rhubarb* &c. When clearing the *Cabbage* plantations, insert a wooden peg or stake beside the finest plants, the tops or hearts of which may be removed for market, but the stamps retained for seed. A willow, or piece of matting, should be tied around the *Cabbages* and *Cos Lettuces* to cause them to heart well. Transplant slips of *Thyme* and *Sage* under fruit trees. Transplant *Parsley* into moderately open situations. Sow a few *Nasturtium* seeds, or a line of *Beet*, along both sides of *Asparagus* beds, or two rows of *French Beans* may be sown on the top of the ridges. Mark, 4 or 5 feet wide, spaces across the *Onion* fields, and set a man with a short narrow hoe in each space to clean and thin the crop. Early *Turnips* that were sown on hot-beds are now pretty large; make, therefore, successional sowings, according to the demand and the land that can be spared for that kind of crop.

## GARDEN STRUCTURES.

## HEATING HORTICULTURAL BUILDINGS WITHOUT COST.

I HAVE just witnessed, at Dromore Castle, County Kerry, Ireland, a method of heating horticultural buildings which, although not quite new, is here, I believe, now for the first time carried out in a thoroughly practical and economical manner by a mode of working in which the cost of fuel is entirely neutralised by a compensating process. I found the principle in full and successful operation, and learnt that it had been patented by Mr. Cowan, the manager of the gardens at Dromore, who is the inventor of the system as at present applied. The principle by which this has been effected is this, namely, that the coal producing the necessary supply of heat is made to perform a distinct operation at the same time, the product of which is sufficient to pay the entire cost of the coal, while the heat, being prevented from escaping, warms a boiler, which supplies the adjoining plant-houses or vineries with a steady heat, under strict control, upon the ordinary hot-water system, from which it differs only in the all-important respect, that it is worked without one farthing of direct cost. Mr. Cowan describes the principle of his invention as the "compensating principle," and tells us briefly in his short but pithy prospectus, "first, it saves the entire cost of fuel; secondly, it does the work with more regularity than the ordinary systems; thirdly, that it requires no night attendance." The system consists, as Mr. Cowan next tells us, of the combination of a lime-kiln with an ordinary hot-water apparatus, and the only wonder is, says Mr. Trench, the well known agent of the Marquis of Lansdowne, that the system, being so simple, has not been adopted long ago. Mr. Trench has seen the system in full operation, and is therefore a competent authority to pronounce an opinion as to its merits. The following statement will show how the entire cost of fuel is saved: Each cwt. of anthracite coal (or coke) produces 3 cwt. of lime, worth 1s. 9d.; cost of limestone, 5d.; cost of coal, 1s. 3d.=1s. 8d.; profit, 1d. In a kiln 8 feet deep, 6 cwt. of lime is produced in twenty-four hours, making a profit of 2d. per day. The labour required, one man two hours per day to an 8 feet kiln to break limestone, charge kiln, regulate boiler, &c., being certainly not more than would be required for an ordinary hot-water apparatus. An 8 feet kiln at Dromore is found sufficient to heat, to any required degree, a range of plant houses or vineries of 200 feet in length, the boiler being an ordinary saddle boiler; and it is calculated that if a boiler, designed like that in the annexed plan, were used, a range of 400 feet might be heated with the same sized kiln. The entire saving of the cost of fuel is of course most important, especially in a commercial point of view, and must necessarily work a complete revolution in the production of all table-fruit requiring heat in its culture, such as forced Grapes, and Grapes in ordinary season; forced Peaches, forced Plums, forced Strawberries, and other fruits; which may henceforth be produced in large quantities, with no outlay for fuel. I have already heard of a company being formed to work the principle largely in the chalk districts of Kent and Surrey,

and doubtless many enterprising horticulturists will only be too glad to adopt a system which promises to secure to them, in every respect, such an enormous saving, and which all may practise on paying to Mr. Cowan a small royalty, the amount of which is not, I believe, at present fixed.

I visited the kiln at ten in the evening, and on examining it, it was quite evident that the 8 feet deep of steady fire would require no stoking, and that it would do its duty through the night for twelve hours more, having been last charged about ten in the morning, so that recharging once in twenty-four hours seems to be amply sufficient. The thermometers in the three different houses stood respectively at 61°, 66°, and 70° Fahrenheit, the heat desired by Mr. Cowan, who assured me that there would be no diminution of heat in the morning, and that he could confidently leave the kiln and houses to take care of themselves, during the night. I visited the houses again at nine the following morning, and found no diminution whatever in the temperatures, though the fire had sunk down some 6 or 7 inches in the kiln.

Supposing the plant for the carrying out of the combined system of lime-making and heating to be put up together, the cost of the addition of the kiln and its appurtenances would only be, for an 8-feet deep kiln, about £10 to £15 more than a stack of fuel-consuming apparatus on the usual hot-water and coal stove principle. Mr. Cowan informs us that he was led to the experiments which have resulted in his now perfected system by the present high price of coals, as he felt that it could not be to the interest of his employer to continue the ruinously expensive heating of the plant and Grape-houses with coals at 35s. to 40s. the ton. The proverb says, "It is an ill wind that blows nobody good;" and the extravagant price of coals has led to what will evidently prove of most material advantage to those who may adopt this system.

DESCRIPTION OF THE DIAGRAM (which is a vertical section of the whole apparatus): A represents the boiler, placed over the cavity of an 8-feet lime-kiln; B, a casing of fire-bricks; C, a coating of sand, kept together by a layer of Portland cement, with an outside layer of concrete. The arrangement of the flow and return pipes will, of course, be easily understood.

H. N. HUMPHREYS.

**The Weather in Northamptonshire.**—Friday, the 25th ult., snowing here all day, succeeded by a sharp frost at night; Saturday, cold, with storms of sleet and snow at intervals during the day; Sunday, cold north winds, turning the osiers yellow. Pear trees in full bloom, so that we again know what to expect in the way of crops of fruit.—R. GILBERT, *Burghley Gardens*.

A WRITER in the *American Agriculturist* quaintly observes, "We are not, after all, up to our English brethren in devising names for horticultural fixtures and appliances. Does frost injure your Peach trees?—Then grow them under the 'Portable Fruit tree Crymbocthus.' If this is not sufficient protection, cover the glass with 'Frigi-domo,' and increase the temperature inside by means of a 'Calorigen.' Should the trees grow out of bounds, you can shorten them with an 'Averruncator,' and should scale, mealy-bug, and the like molest, you have only to apply some 'Phytosmegma.' Truly it must be lots of fun to 'horticult' in England."

Mr. Cowan's Lime-kiln Heating Apparatus.

## ASTERS.

I AM a great lover of the Aster family in its widest sense; in fact, I sometimes question whether I am not a Composite myself. At one season or other of the year you will always find a representative of this family in my garden. At the present moment I have the latest improvement from Paris of the *Leontodon* in all its glory, and in the autumn my "Last Rose of Summer" is the most recently introduced German Aster. Last year there was an unusual number of new names of Asters in the German catalogues, and my old favourites, the *Paeony*, the *Victoria*, *Boltze's Bonquet*, and a few others which had always done me good service, were completely lost in the grandiloquent descriptions and the classical names attached to the new comers. As a few shillings is not a matter of much consequence with me, I thought I would indulge myself in all these grand varieties so puffed up at home and abroad, and accordingly I invested in packets of them all. I can assure you, Mr. Editor, the quantity of seeds received was small compared with the amount of the coin paid for them. But one does not care much about that when a hobby has to be gratified. At the same time I took the precaution to have my usual supplies of my well-tried friends. Well! sir, I would not bother you with my grievance now, but many are at the present time sowing Asters, and I should like them to benefit by my experience. Most of the new varieties proved to be simply bad stocks of well-known kinds. In my note-book the first is *New Bismarck* (I suppose in compliment to the great statesman). I said when I saw his namesakes, "May he never be in such bad company!" They were the tag-rag and bobtail of the flat-petalled Asters, and I was almost going to say something stronger, but I won't. The *Ox-eye Daisy* was a queen to some of them. Next came the *Newest Shakespeare*. Wouldn't the venerable bard have wept had he seen such a desecration of his name? Then there was the *Quilp* of Asters, the *Tom Thumb*, an uncouth starveling, all legs and arms. Oh! dear, I said, is that what I have got for half-a-crown? Next came *Newest Humboldt*—but I shall not further occupy your space. My object in saying so much on the subject is simply to prevent your Aster-loving readers from being taken in as I have been.

LEONTODON.

## JOINTING HOT-WATER PIPES.

Your correspondent's inquiry (see p. 302) respecting the fitness of india-rubber rings for jointing hot-water pipes merits more than a passing remark. My own experience, though small, has satisfied me that these rings make entirely water-tight joints, and are easily fixed, effecting a great saving of time, compared with the old-fashioned mode of packing with hemp and lead. The ring being drawn over the end of the pipe to be jointed, one man holds it steady while another pushes it into the socket, the ring rolling round and becoming flattened and perfectly water-tight as the pipe "goes home." When all the piping is fixed, a little wet Portland cement is run in round the joint with the fingers, and then the whole is complete. Some hot-water pipes fixed here were jointed with these rings, and the men who used them stated that they were greatly superior to the old packing method, which causes delay, and is not infrequently productive of leaks and annoyance. It is, however, desirable to pack such joints as are within a few feet of the boiler, as the heat there is sometimes detrimental to the india-rubber rings.

ALEX. DEAN.

Bedford.

I CAN confidently recommend your correspondent "W." (see p. 302) to use vulcanised india-rubber rings for this purpose, having at the present time several hundred feet of piping, both for top and bottom heat, connected in that way under my own supervision, the greater portion of which was put up about eight years ago, and the remainder at intervals up to as late a period as the end of last year, all of which, I am happy to report, act most efficiently, without a single leakage; and, apparently, the joints will continue sound for an indefinite period. I may add that the system possesses many advantages over iron joints, not the least of which is its non-liability to burst the sockets, as iron-filing joints are apt to do if not judiciously made. Of this a conclusive proof occurred in two greenhouses here, in the shape of nearly every pipe-collar cracking, owing to the use of iron cement, which, doubtless, had been rammed in too hard, or had contained too much sal ammoniac, the result of which was excessive rusting and consequent bursting of the collars. This mishap, however, did not take place all through the work simultaneously, but was prolonged through a series of years, until thorough repairing became necessary. This I did by having the whole of the sockets cut off with a "cold" chisel, and double sockets affixed to the same pipes by means of india-rubber rings. I, therefore, saved the expense of having new pipes. I may add that, should a ring-joint prove defective, either at the time of fixing or afterwards, the evil can easily be remedied, with-

out the necessity of emptying the apparatus of water, by simply ramming in against the ring a packing of yarn, or similar material, until it becomes water-tight, and then filling the remaining space with Portland or other cement. I have, however, found it rarely necessary to adopt such a course, and that only at the time of fixing, owing to a ring fitting improperly on account of its being too small or too large for the socket. It is desirable that the rings should possess substance sufficient only to allow them to enter the sockets with a moderate thrust; but, of the two evils, it is better to have them fit too easy than too tight. Should your correspondent decline to adopt the mode in question, I would then advise him to try Portland cement, which, on the score of economy, he would find preferable even to india-rubber rings, but not comparable to them as regards celerity in the operation of fixing. In durability and efficiency I have proved this cement to be equal to the rings; but my experience does not allow me to advocate either of the systems for making joints in close proximity to the fire heat.

W. G.

It has been discovered by Minnesota farmers that 2 acres of Sunflowers will supply a family with fuel through a long winter. The wood of the stalks and the oil of the seed, it is said, make roaring and cheerful fires.

## COVENT GARDEN MARKET.

MAY 2ND.

**Flowers.**—The supply of these increases as the season advances. Even *Lilium auratum*, both in the shape of flowering plants in pots and cut blooms, has made its appearance; also zonal and show *Pelargoniums*, *Fuchsias*, herbaceous *Calceolarias*, *Cinerarias*, *Heaths*, *Cypripis*, *Mignonette*, *Azaleas*, *Lily of the Valley*, *Callas*, *Ferns*, *Selaginellas*, small *Palms*, *Dracaenas*, and fine-foliated and flowering *Begonias*, now constitute the bulk of plants in pots. Amongst cut flowers are Roses of different sorts, particularly *Maréchal Niel*, *Pelargoniums*, *Cantellias*, *Azaleas*, *Gardenias*, *Stephanotis*, *Pinks*, *Lily of the Valley*, *Orchids* of different kinds, *Forget-me-Nots*, *Nemophilas*, and others. Hardy plants likewise occupy a prominent position: they consist of *Pausies*, *Ranunculuses*, *Anemones*, *Polyanthuses*, *Cowslips*, *Oxlips*, *Primroses*, *Daisies*, *Aubrietias*, *Arabis*, *Wallflowers* (single and double), and a few other things in flower, lifted with roots, and kept moist in boxes until sold. Sweet *Williams*, *Canterbury Bells*, *Lupins*, *Southern-wood*, *Periwinkles*, &c., although not in flower, are brought to market, and meet with a ready sale. Climbing plants, such as *Virginian Creepers*, *Jasmines*, *Ivies*, *Cobaeas*, *Lophospermums*, *Passifloras*, &c., in pots, are also plentiful, and seem to be much sought after. *Nasturtiums*, *Sweet Peas*, and *Tropeolum canariense* are offered in their seedling pots, perhaps from two to four dozen plants being in each pot. In Fern roots, too, there is a large trade just now.

**Fruit and Vegetables.**—Large supplies of American Apples, consisting chiefly of *Newtown Pippins*, have just arrived, and meet with a ready sale. *New Grapes* and *Strawberries* are good and becoming more abundant, excellent supplies of them having arrived from Jersey. *Pine-apples* are in good demand and are rising in price. English grown *Peaches* are of fair quality, but as yet scarce. *Cucumbers* are plentiful and good. *Green Gooseberries*, fresh *Capsicums*, *Green Peas*, *Beans*, *Kidney Beans*, and salad are furnished in moderate quantities, and of other vegetables and Potatoes there are good samples and ample supplies.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Cobs, per lb., 2s. to 2s. 6d.; Grapes, both house, per lb., 10s. to 18s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 6s. to 12s.; Peaches, per doz., 1s. to 3s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 8s. to 12s.; Strawberries, per oz., 9d. to 1s. 6d.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100 5s. to 10s.; French, 4s. to 10s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, young, 1s. 6d., old do., 8d.; Cauliflower, per doz., 3s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 6d. to 2s.; Endive, per doz., 2s.; Fennel, per bunch, 3d. to 4s.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz. 1s. to 2s.; Mushrooms, per pot, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 5s. to 8s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 6s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 5s. to 8s.; Potatoes, per bushel, 5s. to 10s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsafly, do., 1s. to 1s. 6d.; Savoy, per doz., 2s. to 3s.; Scorzoneria, per bundle, 1s.; Skate, per basket, 1s. to 2s.; Shallots, per lb., 3d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, old, per bunch, 3d. to 6d., young do., 2s.

## ANSWERS TO CORRESPONDENTS.

**COMMON LAURELS (M. T. W.)**.—They strike readily from cuttings taken off, and put in in autumn.---**GROUND VINERIES (A Subscriber)**.—We know of none better than those made by the firm you name.---**PRIMROSES (Ambleside)**.—An abnormal variety of the ordinary yellow *Primrose*, and when seen in perfection no doubt very pretty.---**CONSERVATORIES (A. K.)**.—We know of no book on the subject worth consulting.---**NAMES OF PLANTS (Rocks) next week**.---(G. B.)—1. *Pulmonaria maculata*; 2. *Berberis Darwinii*; 3. *Prunus triloba*; 4. *Berberis dulcis*; 5. *Retinospora pisifera*; 6. *Pteris scaberula*.---(Royston).---*Opuntia microdasys*, and *Amelanchier Botryanthum*.---(E. S.) 1. *Oxalis*, sp. indeterminate; 2. *Scilla amona*; 3. *Ornithogalum umbellatum*; 4. *Anemone Pulsatilla*; 5. *Fritillaria Melegris* var.; 6. *Leucojum aestivum*; 7. *Omphalodes verna*; 8. *Orobanchium*; 9. *Muscari botryoides*.---(Gardener).---1. *Aspidium cornaceum*; 2. *Cyrtomium falcatum*; 3. *Lastrea elabella*; 4. *Athyrium Filix-Fem. Smithii*; 5. *Pteris serrulata*; 6. *Pteris serrulata* var. *corymbosa*.---**BOOK ON GREENHOUSE PLANTS (S. E.)**.—Williams on Stove and Greenhouse Plants, published by the Author.---**THE SNOWFLAKES (P. R. S.)**.—All are hardy and worthy of a place in every garden.

# THE GARDEN.

—o—o—o—  
 "This is an art

Which does mend nature: change it rather: but  
 THE ART ITSELF IS NATURE."—*Shakespeare.*

## FLOWERS AND HEALTH.

It suited a poet once to pen the well-known line—"Die of a Rose in aromatic pain," and there have not been wanting plenty of alarmists as to the perils of sleeping in rooms where large quantities of particular kinds of flowers have been temporarily deposited; sometimes, no doubt, with good reason, for it has been proved by experience that certain individuals are affected seriously by certain odours, the odoriferous matter being not a mere invisible aura, but a substantial exhalation, capable of being taken up after the same manner as the gases produced by sundry chemical experiments. The Narcissus, the Wallflower, and several others, appear to have furnished definite cases of this nature. Similar charges have been brought, more or less justly, against certain trees, shrubs, and even herbaceous plants, invisible emanations from which are reputed to cause nausea, insensibility, and even death, the famous fable of the Upas having a fractional amount of truthful realisation. The Manchinel tree of the West Indies, and certain American species of Rhus are generally understood to be capable of thus vitiating and even poisoning the atmosphere that immediately envelopes them, though the effects are manifested only in persons who are predisposed to suffer from malaria. These statements rest, no doubt, upon a certain basis of fact, but more numerous observations, and greater precision in determining how much is *bonâ fide* cause, and how much is veritable effect, are still needed in order to a right apprehension of the degree to which plants can injure man seriously through his nostrils. Simple unpleasantness of odour is of course quite another thing, often a matter merely of fancy or education, and cannot be in any degree associated with deleterious qualities in the plant affording it, since we have noisome scents in some of the harmless Labiate, such as the *Stachys sylvatica* and the *Ballota nigra*, the very name of which last, facetiously derived from *ballein*, to "cast away," is intended to imply its unanimous rejection by respectable noses, or at all events by the average nose of civilised Europe, while, *per contra*, there are plants of vicious properties that afford scent truly delicious, as for example, the common *Mezereon*. With modern science to give us lessons, we find however, that the ill effects produced by the odours of one set of plants and flowers are balanced, perhaps quite overmatched, by the good effects of other sets. Most of us have heard of "ozone." It is one of those capital ingredients of the world that have existed from the beginning, but which have only of late years been actually recognised, and consists, in plain English, of highly electrified oxygen, the gas when so electrified acquiring specially good qualities in regard to the general health of mankind. Professor Montegazza, of Padua, states that certain plants and flowers, upon exposure to the rays of the sun, cause so large an increase in the quantity of ozone round about, as to be eminently conducive to a better condition of the atmosphere, of course with the understanding that there is proper ventilation, such as will carry off the excess of purely odorous matter that may arise from them. Among these ozone manufacturers of the botanical world are the Cherry Laurel (poisonous in its leaves and kernels); the Clove, Lavender, Mint, Fennel, the Lemon tree, and others; also the Narcissus, the Heliotrope, the Hyacinth, and Mignonette. Certain prepared perfumes, similarly exposed to the sunshine, add further to the atmospheric stock of ozone, the well-known Eau-de-Cologne for instance, oil of bergamot, extract of millefleurs, essence of Lavender, and some of the aromatic tinctures. The oxidation of certain essential oils obtained from plants and flowers, such as the oils of nutmeg, aniseed, Thyme, and peppermint, is likewise indicated by the professor as a source of ozone, though the supply of this pleasant aerial condiment is in the case of these less considerable. Dr. Mantegazza recommends accordingly the large and sedulous cultivation of ozone-

producing plants in all districts and localities where the atmosphere is liable to be corrupted, marshy places in particular, in which last, according to Dr. Cornelius Fox, in his recent comprehensive work upon ozone, it is impossible for any better sanitary agent to be introduced than the common Sunflower. This plant, happily able to make itself quite at home in the poorest cottage backyard, has been shown not only to purify the atmosphere of marshy places, removing a very decided amount of the miasmata ordinarily there engendered, but to confer the positive benefit of augmenting the quantity of ozone. People are recommended often to the seaside, or to special marine watering-places, for the sake of their reputed wealth in ozone. Should we not move a vote of thanks to the man who has shown us how to arrange for supplies upon our own premises?

In past ages there appear to have been instances of a sort of instinctive resort to certain plants as disinfectants. Herodian relates that during a plague in Italy, in the second century, strangers crowding to Rome were directed by the physicians to retreat to Laurentum (now San Lorenzo), a place so called from the abundance of *Laurus nobilis*, or Sweet Bay Tree, which then grew there, and by inhaling the odour of which they would in a certain measure be guarded from infection. And long before the time alluded to, the disciples of Empedocles had been accustomed to plant aromatic and balsamic herbs in the neighbourhood of their dwellings, in the confident belief that by so doing they were providing means of defence against fevers, &c. To this day we have the name of "Feverfew" as the appellation of one of the strongest-scented Compositæ, with traditions of its abounding febrifugal powers.

So that if we are wise we shall imitate the citizens of Laurentum, and promote the growth of Bay trees wherever the soil and climate will allow them to flourish. If the experiment should fail as regards miasmata, we shall at all events be so much the richer as to a fragrant evergreen; and if we are wise, we shall further encourage and help forward the diffusion of odour-yielding flowers, such as yield this excellent ozone, in the gardens, &c., of towns and their suburbs, promoting the healthy qualities of the atmosphere after the most beautiful and picturesque of methods. Mignonette, Thyme, Lavender, Sunflowers, will grow almost anywhere, operating their quiet but solid usefulness in a way that is least of all expected. The purification of the atmosphere from a portion of its carbonic acid gas goes on all the same, and uninterruptedly; the ozone manufacture is a distinct and independent performance, and belongs to the flowers alone, just as the former pertains to the green foliage only. The more that chemistry discovers in relation to the ozoniparous properties of flowers, the more valuable will flowers become to reflective minds, and to all who are satisfied, like ourselves, that simple beauty is invariably the index to some large and admirable fact of the practical kind; and thus it will appear in the end that the florists and others who devote themselves to the teaching of aesthetics combine therewith, unconsciously, the benevolent functions of the sanitarian.

LEO GRINDON.

THE value of *Laportea pustulata* as a textile plant is now occupying much attention in Germany. This plant, which is known in N. America as the Wood Nettle, was discovered some years since by M. Roezl on the Alleghany Mountains at an altitude of more than 5,000 feet above the sea level. Some living specimens which he brought home were disposed of to the Prussian Minister of Agriculture, who was desirous of ascertaining the value of the plant under cultivation. The results, so far, appear to be favourable. Being a perennial, the *Laportea* does not require to be sown every year, and, in this respect, has some advantage over Hemp and Flax; besides which, it is far less troublesome and less expensive than Hemp in the preparation of its fibres. In the wild state it grows from 2 to 3 feet high; but, as grown at Berlin, it has already reached a higher stature, which it is probable will be still more extended by careful cultivation in suitable soil. The experiments which—as yet to a limited extent only—have been made as to the quality of the fibre, tend to the conclusion that it will form a valuable addition to our textile materials. We may add that the plant grows rapidly, and is easily multiplied by division of the stools, or by root-cuttings.

## NOTES OF THE WEEK.

— THE thirtieth Anniversary Dinner in aid of the funds of the Gardeners' Royal Benevolent Institution is announced to take place on Wednesday, the 2nd July, when the Right Hon. Lord Henry Gordon Lennox, M.P., will preside.

— A FINE late white Broccoli, named Northampton Hero, sent to us by Messrs. Watts & Son, of Northampton, promises to be an acquisition. Its heads are large, white, and compact, and their flavour excellent.

— ON Tuesday afternoon their Majesties the King and Queen of the Belgians honoured the establishment of the Messrs. Veitch at Chelsea with a visit. They were conducted through the various departments by Mr. H. J. Veitch, and were pleased to express themselves much delighted with the many attractions of this nursery, more particularly with the specimen Azaleas, pot Roses, and Orchids, now in great beauty.

— To the wonderful excellence of imported Newtown Pippin Apples, and to their abundance in our markets this year, we have several times alluded. Earlier in the season they could only be had at our best fruit shops at from threepence to fourpence apiece; but now London hawkers are selling them in the streets at a penny apiece. Though a little deteriorated in flavour, through long keeping, everybody has therefore now an opportunity of tasting this fine American Apple.

— AT the meeting of the Royal Horticultural Society on Wednesday last, Mr. C. Turner, of Slough, showed some of the finest specimens of pot-grown Roses ever yet exhibited. As a rule they measured about 6 feet in diameter and as much in height, each plant being furnished on an average with at least a hundred expanded flowers. The blooms, too, were large, excellent in form, and bright in colour; the foliage abundant, and fully as fine as ever we have seen it on Roses grown in pots.

— WE have received from Mr. Horley, Toddington, Beds, a portable frame, which seems well adapted for the growth of salads, or for protecting Scarlet Runners and things of a similar character, from frost. It is made in lengths of 4 and 6 feet. It is span-roofed; the glass, which is moveable, can be slipped readily in and out at pleasure, and altogether it looks as if it would prove extremely useful as a protector and promoter of growth in early crops.

— A NICE plant of the comparatively new *Veronica Hulkeana* was shown at South Kensington on Wednesday last by Mr. Macintosh, of Hammersmith. It is a New Zealand species, which, growing as it does on mountains at considerable elevations, may possibly prove hardy in some of the warmest parts of England. It forms a little small-leaved bush, from 2 to 3 feet in height, and produces spikes of pretty light mauve-coloured flowers from the middle of April to the end of June. A plant of it stood out of doors uninjured during the last two winters at Hammersmith.

— A PAPER by Mr. Howard, read to the Linnean Society the other night on the Cinchonas, though dealing with questions of variation and "sport," interesting principally to botanists, contained this interesting fact: Plants raised from seed from the same pod have been known to produce very different kinds of bark, some yielding excellent quinine in large quantity, others giving bark absolutely worthless for medicinal purposes. No explanation can be offered, but the cultivators of Cinchona can avoid the chance of this failure by always propagating by cuttings, and not trusting to seed. With the possibility of this valuable medicine becoming scarce this is important.

— COL. WILDER stated, in a letter to the Massachusetts Horticultural Society, that the *Rhododendron* and *Azalea*, distinct genera, had been hybridised, but that no one had ever succeeded in making a hybrid between the Apple and the Pear, or between the Raspberry and the Blackberry, which belong respectively to the same genera. It was doubted for a time that hybrids could be obtained between the *Vitis vinifera* and *V. labrusca*, but several cultivators have settled the question and produced them. Col. Wilder said that his earliest experience in hybridising was in the floral kingdom, in crossing species and varieties of the *Camellia*. He discovered that, to produce double flowers, it was important that the pollen be taken from a *petaloid anther*, that is, an anther borne on a small petal (the filament being flattened out in its first remove from its original form), and that this was still better if from a double flower. He also performed interesting experiments with the Lily; the first was with the red Japan and the Tiger Lily. Seedlings were produced with different shades, from delicate rose to dark crimson. He also found that pollen preserved its fertilising power a long time. In one instance, a camel's hair pencil, which had not been used for several days, was found with pollen on it. This was applied to the stigma of a Lily, and produced fertilisation. In another instance, he fertilised with pollen carried a long time in his pocket. The science of hybridisa-

tion, says Col. Wilder, is yet in its infancy. To use the language of Dr. Lindley, "We have but stepped over the borders, and the whole field of hybridising lies widely spread before us; its boundaries are lost in the horizon, and we shall find them still receding as we advance."

— THE Fairfield Orchids are, we understand, to be sold by auction; the sale is to commence on the 12th inst., and it is expected to last some seven or eight days.

— DR. KELLOGG, the discoverer of *Lilium Bloomerianum*, states that it is the most magnificent Lily of the Pacific coast. Its flowers are large, nodding, of a beautiful orange hue, and studded with rich dark spots. It grows from 6 to 10 feet high, and under high culture four to six stems are produced from a single bulb.

— THE Kibble Art Palace and Conservatory, erected by Messrs. Boyd in the Botanic Garden, Glasgow, was opened the other evening for private view, prior to its public opening, which is expected to take place soon. Fifteen hundred visitors availed themselves of the opportunity to inspect this really beautiful winter garden.

— SOME fine new Grapes were shown at South Kensington the other day, from the Royal Gardens at Frogmore. They consisted of several clusters of Black Hamburg and of Buckland Sweetwater, the berries of both of which were large, plump, finely ripened, and covered with a beautiful bloom. They were the produce of one-year-old pot Vines.

— FEW succulents are handsomer, when seen *en masse*, than the two orange-flowered *Mesembryanthemums aurantiacum* and *auroam*, specimens of both of which have been brought under our notice by Mr. Thomson, of Penge. Mr. Thomson, we understand, has some thousands of these plants now in full bloom, and when seen on a sunny day, the effect produced by them is striking in the extreme. They require only the protection of a frame in winter, and, coming into bloom as they do early in the season, they make suitable plants for window decoration.

— WE are glad to observe that the skill in spring gardening shown by Mr. Roger when gardener at Berry Hill is now beginning to be used with good effect in the adornment of Battersea Park. A beginning has been made near the west lodge, and that part of the park now presents an aspect much superior to what it used to have when the beds were left empty except in summer. We are glad of this beginning, as we see no reason why a fine display of spring flowers might not be made in the light soil of Battersea Park as well as anywhere else. Spring flowers, with the exception of the commoner kinds of bulbs, have hitherto been much neglected in our London parks.

— FROM some experiments made in Berlin, with the view of determining what damage is really done to the roots of trees and shrubs by coal-gas escaping from pipes and permeating the soil, it has been found that even so small a quantity of gas as 25 cubic feet per day, distributed through 576 cubic feet of earth, rapidly killed the rootlets of all trees with which it came in contact.

— AS an instance of the rapidity of the growth of trees in tropical regions, the *Panama Star and Herald* states that two years ago the Aspinwall Hotel at Panama was burnt down, and that the ground for some distance round the building was completely cleared of vegetation by the fire. On this space there has already sprang up a luxuriant growth of trees, some of which are no less than 32 feet high. These are *Cecropias* or Trumpet trees, whose branches, growing at right angles with the trunk, have reached the ruined walls of the hotel, and are now crowding through the doorways and the higher windows in such numbers and with such force of growth that it is expected the walls will soon be completely levelled by the pressure.

— GEORGE SAND's eloquent protest against the mutilation of Fontainebleau Forest seems to have borne some fruit, for we learn that a committee has been formed in Paris for the purpose of protecting it, not only from the woodman, but from the manufactories which are beginning to encroach upon its borders. It appears that the timber which is marked for felling will yield but an insignificant price; still, though the value of certain Beeches and Pine trees may be small from a commercial point of view, they are at least deserving of respect as artistic studies, and because they have been illustrated by Diaz and Théodore Rousseau. It is asserted that some of the Oaks are more than 400 years old, and their age should protect them from destruction, if only because, when felled, they would be comparatively worthless. The Forest of Fontainebleau was, until the Revolution, known as the *Forêt de la Bière*; but it was converted into a Royal domain by a decree of Henri II. in 1566. It is to be regretted that the measures which he took to preserve it from desecration have not been adhered to in these latter days; and it may be hoped that the committee will succeed in getting the Administration of the Fine Arts, within whose province the woods and forests lie, to preserve it from further injury.

## THE ARBORETUM.

### HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

#### THE STRIPED-BARKED MAPLE (*ACER STRIATUM*).

This forms a somewhat erect-growing deciduous tree, which attains a height of from 15 to 20 feet, and has a somewhat open head, irregular in outline, and the stem and branches covered with smooth green bark, elegantly marked longitudinally with white stripes. It is a native of North America, where it may be found anywhere between Canada and Georgia, and thrives best in a rather moist situation. It was first introduced in 1755. Its shoots are long and stout, and the buds

sure ground. The synonymes are *Acer canadense* and *Pennsylvanicum*, and the local names, Moose Wood and Snake-barked Maple. The length of a full-sized leaf is 10 inches, including the footstalk, which is from  $2\frac{1}{2}$  to 3 inches long, and the breadth from  $5\frac{1}{2}$  to 6 inches.

#### EFFECTIVE GROUPING OF TREES IN SPRING.

A BACKGROUND of Scotch Firs, dark, dense, and impenetrable, pin-cushioned here and there with tall wild Cherries, Geans, and Service trees, the white buds and white downy leaves of the latter looking like bunches of flowers. In front, groups of Crabs, Apples, and Pears, with flowers ranging from the

*Acer striatum.*

Fruit or Keys of *Acer striatum*.

and leaves when they first begin to expand, which is very early in the season, are of a rose colour. The leaves are large, thick in texture, three-lobed, cordate at the base, finely and acutely toothed on the edges, quite smooth on both surfaces, and set on rather long footstalks; they are deep glossy green above, and, just before they fall in the autumn, turn to a light chestnut, or yellowish-brown. The lobes are rather angular, not very deep, and very acutely pointed; the flowers are of a greenish-yellow, and are produced in long, pendulous, simple, terminal racemes; the keys or fruit are smooth, bright green when young, and brown when ripe, with the wing rather diverging, and the carpels remarkable for having a hollow depression on one side. Owing to the beauty of its bark, and its fine large leaves, this Maple deserves a place in every plea-

most brilliant pink to the purest white. Groups of Almonds and Peaches are fitted in between or carried in lines of beauty through the pinks and whites. A little further on the Laburnum is found bursting its hanging racemes of gold, while rising up to meet these are lilacs showing their bunches of blossoms and tender leaves. These again rest on a cushion of fine-foliaged Aucubas, and the ground-line is reached through a floral band of early Rhododendrons and Heaths. Surely a spring scene such as this might be enjoyed in every garden, were foresight and judgment allowed to preside at the planting of the grounds. But the object of planting is mostly to shut out something as rapidly as possible—an ugly object, the wind, the view of some one else's property—and hence planting is too often done hurriedly and with the one object of forming a

blind or screen. But if blinds or screens must be had, why not, at least, try to render them beautiful? In olden times no labour was thought too great by the daughters of the wealthy to render fire-screens, curtains, tapestries, &c., exquisitely beautiful. We might with much advantage copy the example of the ladies of the olden times in rendering our garden screens, that is, plantations and shrubbery belts, as beautiful as possible. Every year adds to our materials, and we only lack taste and skill to make the most and best of them. Almost every tree and shrub may have its beauty increased by its accompaniments in shape, colour, size, style, and season. It is, therefore, high time that at least as much (if not more) care were exercised in the arrangement of shrubs and trees for effect as is expended in the arrangement of flowers.

D. T. FISK.

**The Deciduous Cypress.**—I was very much pleased to see your capital illustration of the fine specimen of this at Syon, and trust it may serve to remind many of the high value of the tree. Apart from those remarkable root-knobs which, as shown in your engraving, give the tree quite a distinct character, and impart much interest to it, its value in the garden-landscape is priceless. Nothing equals the soft tender green of its summer dress, and in winter, it is when matured, one of the most distinct and striking of deciduous trees. In days when people are busy planting scores of expensive Conifers, the value of which for this country is as yet unproven, your picture of one of the noble deciduous Cypresses at Syon can hardly fail to do good, by calling attention to a tree of tried excellence and great beauty.—*APPEAL.*

**The Birch as a Pleasure Ground Tree.**—It seems surprising that the Birch, which is sometimes called "The Lady of the Wood," is so seldom admitted into the garden and pleasure ground. In habit, general style, beauty of stem, colour, and form of leaf, what tree is more beautiful or pleasant than the Birch? It looks well singly, or in groups, or associated with almost any other trees. Against purple-headed Limes the green foliage of the Birch looks soft and rich. Standing up among Arbutus, what a contrast of habit and of colour is produced! Birch trees also look grand towering up with clear stems far above the heads of glossy Laurels or Hollies, or glowing Rhododendrons. Indeed, everywhere they have a graceful, dressy appearance; and, unlike so many other trees, their roots prey but little upon those of their neighbours. And yet, somehow, Birches are comparatively little used for ornamental purposes. There are a good many varieties of the white, paper, and other Birches; but perhaps the common white, the cut-leaved, the variegated, the weeping or pendulous, the broad-leave and hairy-twigged paper, and the Poplar-leaved are as interesting as any. All the Birches are, however, useful, and almost all shrubberies and plantations would be improved by their presence.—*T.*

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Edwardia grandiflora.**—What a noble wall shrub this forms, with its large golden pendulous flowers! It is in full beauty in May, and on sunny walls in southern England it grows and blossoms freely.—*W.*

**The Dwarf Almond.**—I cannot help recommending this to your readers, it is so dwarf and bright in early May, looking in my border like a slender-stemmed and elegant herbaceous plant, and full of gay flowers.—*W.*

**Piptanthus nepalensis.**—This well-known plant is a capital subject with which to cover walls, as has been proved often in mid part of the country. It is, however, harder than is generally supposed, as a portion of wall at the Heatherside Nurseries is now covered with its yellow blossoms.—*G.*

**Exochorda grandiflora.**—What a lovely wall shrub this makes! A specimen on the terrace wall at Linton Park, is now (May 2) adorned with strings of white pearl-like buds and beautiful pure white flowers. It is one of the finest flowers of early summer, and ought to be planted extensively against houses and on walls.—*R.*

**Leptospermum lanigerum.**—At Heatherside the other day we were pleased to see the lovely white flowers of this New Holland shrub opening as bravely as those of our hardy spring-flowering trees. In early summer it becomes quite white with blossom, and it continues to bloom all the year round. It is quite hardy, and deserves a place in every collection of shrubs.

**Wistaria (Glycine) sinensis.**—This looks well on the roof of a greenhouse, or on an ornamental trellis in a temperate conservatory. In such positions it is now producing beautiful racemes of lilac flowers in abundance, accompanied by foliage of the freshest green. The blossoms, too, are deliciously fragrant. There used to be a noble specimen of this best of wall plants in the arboretum at Chiswick. Is it destroyed? or has it escaped destruction, though banished from the garden which it graced so long?—*R.*

**Diseased Wellingtonias.**—I have several Wellingtonias in my garden, which were planted some seven or eight years ago. This last year they have all turned a rusty brown, and have got to look thin, dried-up, and withered, as if scorched—the soil is a stiff sandy clay. Can any one furnish me with a remedy? Does smoke, for I live in the heart of a manufacturing district in Yorkshire, have any effect on them. All other shrubs in the garden have thriven well.—*G. R. G.*—[All kinds of Conifers dislike smoke, from the ill effects of which your Wellingtonias are doubtless suffering].

## THE FRUIT GARDEN.

### PEARS THAT SUCCEED ON THE QUINCE.

BY JOHN SCOTT.

THE following is a list of most of the first-class Pears that grow very freely upon the Quince stock, and that will continue for many years to thrive and bear good crops of fine fruit when grown in that way. I have scrupulously given those only that are of first-rate quality, and which luxuriate upon the Quince; at least they do so in my soil, which is a sandy loam, intermixed with a portion of gravel, and resting upon a subsoil of sand, or rather sandy loam, and which becomes light sand as we descend, interspersed or rather traversed by horizontal layers of rock to a great depth. Our water-springs are from 10 to 15 feet below the surface, and are generally found when the first layer or bed of rock is perforated. In fact we never know what it is to be too wet or too dry. In such a soil as this, most fruit trees grow healthily and freely, although the fruit produced is not of the largest size. To get size we should require more clay. A peculiarity of this locality is the absence of scale and other tree insects, especially American blight or mealy bug. This last will not live upon our orchard trees, and although it is often imported into my collection, it never remains with us, and when we receive trees affected with it we take no notice of it, but plant them amongst the rest, being certain that it will not make any progress, but die off; however in very warm seasons it will put in an appearance upon old gnarled trees, but in ordinary seasons it entirely disappears. Lichen and Moss, too, make no head here, unless a tree is unhealthy, or planted near a stream, or shaded from the free action of the air. I have long tried to divine the cause of our exemption from mealy bug and lichen, and have formed the opinion that we are favoured by the south-western gales, that carry the saline vapour from the sea up to us. We are only 14 miles in a direct line from it, and after a storm the saline deposit is distinctly visible upon our windows. Two or three weeks ago I gave you a list of those sorts of good Pears that require to be double-grafted, and I now furnish the names of those that grow most freely. Between these two classes there is a numerous class that grow well, and bear well, and many of which are as fine as those enumerated below, so it may be taken for granted that all the first-class sorts, not named in either of the two lists given, belong to the section of medium growers. Oberdieck, the celebrated German pomologist, says that Pears, or at least most of the varieties, do best upon moist soil. This is perfectly true so far as Pears worked upon the Quince are concerned, but it must be taken with a qualification as regards Pears worked upon Pear-stocks, for if the soil is too moist, the trees will make too much strong watery wood, and become consequently barren, and subject to be frost-bitten, which produces canker and decay. Therefore all naturally moist soils should at least be well drained before trees on the Pear-stock are planted, and whenever they show symptoms of over-growth, root-pruning should be resorted to; for, unless we can get well-ripened wood, we need hardly look for fruit. This is well borne out by Pears worked upon the Quince. On it they make short, well-ripened wood, and, as a matter of course, are annually loaded with flowers, and would also be so with fruit, if it were not for our untoward months of April and May, which, for several years past, have almost destroyed all our Pear crops, and many trees likewise. I am now writing (April 21th) within ten yards of a good registering thermometer, which is falling fast towards the freezing point. It is now ten o'clock p.m., and I expect, from the rapidly-falling glass and a bitter north-east wind, that we shall have 6° or 8° of frost by seven o'clock to-morrow; then there will be lamentation and mourning in the gardens, which are to-day, where Pears are much grown, in gorgeous floral beauty. I have added to the most luxuriant growers in the list an\*, to enable any one to choose the strongest sorts, when their soils are too light to grow the more shy kinds; and I would advise all who wish to have fine Pears to grow them upon the Quince stock, selecting the sorts that are suitable for their soils, and where the soil will not grow them well upon the Quince, then grow them double-grafted, and plant them 4 feet apart, either along the edges of the walks or in a square by themselves; 100 trees would form a square 40 feet by 40 feet, and might

easily be covered in April and May with thin bunting, and thus ensure a good crop :—

STRAWBERRIES IN POTS.

I MAY not be able to say much that is new on this subject, but the following remarks are the results of my own practice, which has been very successful. In order to obtain fruit very early in the season, arrangements must be made to secure the earliest runners that are produced, so that the crowns may be ripened early in autumn. Runners that are taken late will, if forced early, produce a large percentage of "blind" plants. One gardener, who forces a large number early in the season, told me that eighty per cent. of his plants failed to throw up flowers this year, a circumstance no doubt attributable to the above cause and to the unfavourable season last year. My plants of Black Prince, which had ripe fruit in March, did not fail to the extent of five per cent.; and Keens' Seedling, which succeeded them early in April, was even more satisfactory. As soon as the runners are ready for layering, a number of 60-sized pots should be filled with soil which has been previously prepared. The best compost for them is four parts of turfy loam and one part of short stable-manure, such as is usually prepared for Mushroom beds. In preparing the pots, no drainage is required; a little of the fibry portion of the loam is placed in the bottom, and over it a pinch of soot, to prevent the ingress of worms; the compost is then pressed in firmly. One matter, though a small one, is worthy of note, and that is, not to place the pots singly on the beds, but in rows closely together, for the convenience of watering them. The runners should be kept in their place by a small peg. In two weeks the plants will be established, when they may be removed from the parent plant. The pots should be placed on a bed of ashes, or some hard bottom, and an airy position, where they are fully exposed to the sun, should be selected. In two or three weeks the small pots will be well filled with roots, and the plants should be potted into the fruiting pots; 5-inch will be large enough for the earliest, and 6-inch for the late-fruiting plants. In potting, the compost should be well rammed in with a wooden rammer, as firm potting is essential to successful culture. The depth of planting is also very important. The plants should not be placed deeper in the fruiting pots than they were in the small ones. It is also very necessary to choose a suitable position for the plants after they are potted. The plants should not be crowded together, and they should have an open position, fully exposed to the sun, with a little shelter, if possible, from the north and east. I generally place them on one of the kitchen garden quarters which has been cleared of a crop of early vegetables; the space is made level, and as it is not convenient in this case to cover the ground with ashes or some similar material, to prevent the worms from coming up, I place bricks flat on the ground, and on these the pots stand. Not only does this effectually prevent the worms from getting into the pots, but the air circulates more freely underneath than when the pots are placed on the level ground. When worms get into the pots, they do much damage by loosening the mould, and also by stopping the drainage. They may be destroyed by watering the plants with clear lime-water, or the plants may be turned out of the pots, and the worms picked from the ball, returning it back intact into the pot again. During the summer and early autumn months, the plants will grow very rapidly. All the attention they require is to pinch off the runners they produce, and supply them plentifully with water. The leaves are sometimes attacked by a small green maggot, which must be destroyed by hand-picking. Red spider is the most troublesome pest to the Strawberry grower. In hot, dry seasons, the plants are oftentimes attacked before they are potted; if so, an opportunity will be afforded to dip the plants in some solution destructive to this pest while they are being potted. Should it appear afterwards, syringe the plants well with clear water until the insects are dislodged. The plants must not be left out of doors too late in the autumn, as, should the pots get saturated with wet, the roots will be injured. There are various ways of disposing of them at this season of the year; but nothing answers better than to stand the plants on shelves near the glass, in pits or houses, which can be heated in the event of severe frosts setting in. Cold frames answer very well, but the pots must be plunged, to prevent the frosts from getting to the roots. Another way is to lay the pots on

the ground out of doors; they are laid down in a double row, close to each other, bottom to bottom; all the interstices are filled with ashes, another double row is then placed above them in a similar position, and so on with other pots until a stack six pots deep is formed. They do very well in this way, and do not require watering, as the pots absorb moisture from the rain that falls on the ashes. The plants, after being stored for the winter, will require but little attention until they are introduced into the forcing house. The time when they are brought in must be regulated by the time the fruit is required. I have picked Black Prince in February, and to obtain them so early as this, they must be started in a gentle heat about the middle of November—45° at night will be a sufficiently high temperature to begin with, raising it to 50° after the first fortnight. Whether the plants are started at that time in a house specially provided for them or in an early vinery they must be kept close to the glass and fully exposed to the sun. By the time the plants are in bloom the night temperature of the house should be maintained not lower than 55°. A moderately dry atmosphere, with a constant circulation of air, will cause them to set freely. A camel-hair brush should also be passed over the blooms; it can be done very quickly, and is necessary so early in the season, when the sun, if it should appear at all, has but little effect. The fruit, as soon as it is set, must also be thinned, only those that have set well being allowed to remain. I may say that the only Strawberry I have found to succeed with very early forcing is Black Prince. Many others have been tried, but none are so sure to throw up trusses or to set the fruit freely afterwards. Keens' Seedling is the best second early, followed by President and British Queen, to come in before the early sorts from the open ground. In many soils British Queen is uncertain, but with the method of cultivation which will be explained in a future paper it seldom fails to bear a good crop of fruit. The essentials to obtain good fruit from early forced Strawberries are a moderately dry atmosphere and a free circulation of air over the plants. A night temperature of 60° suits them well, and the fruit should be supported above the leaves with short sticks. Nothing answers better for this purpose than sprays taken from old birch-brooms, cut to the proper length, with the small side branches cut back, leaving clefts, over which the fruit hangs. Three or four of these placed in a pot will be sufficient.

J. D.

#### FRUIT PROSPECTS ON WALLS.

THESE are, upon the whole, good. Cherries and Plums promise a profusion of fruit; and, unless the snow-storms of April 23 and 24 bring too much frost after them, it is to be hoped that these most useful fruits will be abundant this season. It is almost too early to write definitely of the other three great wall crops—Peaches, Nectarines, and Apricots; but not too soon to note peculiarities and imperfections of their blooming. The chief of these are piecemeal opening and a deficiency in the size, colour, and number of the blossoms—Apricots especially have bloomed more scantily than I ever remember to have seen them, and this has been rendered more conspicuous by the flowers opening only by a few scores at a time. It is difficult to account for this mode of blossoming. The wet season of last year may readily explain their scanty crop of bloom; but it throws but little light on this intermittent mode of opening. I observe, however, that most of the flowers have set well, and also that the flowers have been shot off the embryo fruit sooner than usual. The flowers seem thinner in texture, and altogether more flimsy than they are wont to be. This want of substance may explain their early fading and falling, which is a misfortune, as the dead blossoms ordinarily form most useful shields to the embryo fruit. Peaches and Nectarines have expanded more regularly and set with wonderful rapidity. I observe in them the same early shooting of the dead blossoms, probably from the same cause—lack of vigour and substance. I have seldom seen such small fruit already naked. Under glass I consider this early shooting of the bloom an advantage. When it hangs too long, it injuriously compresses—occasionally strangles—the fruit, and almost cuts it in two. But out-of-doors the longer the blossoms adhere

to the fruit the safer it is. Almost everything depends on the next three or four weeks. With genial weather the walls may yet be furnished with their full complement of Peaches, Nectarines, Apricots, Plums, and Cherries. The latter like a wet season. I have never seen the blossoms more numerous and vigorous than they are this spring. To say the walls are whitened over with their pure white bloom conveys an inadequate idea of the profusion. There is in fact no wall visible, it is all Cherry blossom, and this more especially when the most profitable of all modes of Cherry training is adopted—that of fixing the leaders to the wall, and allowing the out-growth to jut out a foot or more from it. This half-standard style ought to be called the fill-basket mode of training; it also suits the trees well. No gum or canker appears on those trees, which are allowed to keep up their stamina by freedom of growth. Morellos also do well trained in the same way. The shoots should be merely thinned and shortened at the winter pruning. Protection must be afforded for at least another month, and every leaf and shoot should be left on Peach and all other wall trees till the middle of May. These will cover and shelter the young fruit better than any artificial substitute, because they are nature's own provision for this especial purpose. Alone they will often bring the crop safely through the night frosts and cutting winds of our ungenial springs. They also powerfully aid all other means of protection, such as glass and wooden copings, glass frames, bunting, woollen nets, &c. One of the greatest follies we can commit is to go to the trouble and expense of artificial protectors of all sorts and sizes, and then recklessly cut off the shoots and leaves provided for this express purpose by the plant itself. Besides, surely it is a practice as unnecessary as it is injudicious. The young shoots at first neither rob each other nor the roots. They only use the supply of sap laid up for them in the autumn, and, when that is exhausted, they wake up the roots to furnish more. It is rather a nice point in vegetable physiology to determine exactly at what period of their growth this awakening occurs. But it may be safely affirmed that long before there is any serious loss of root force, from the feeding of superfluous shoots, it will be quite time for the latter to be removed, the fruit having become sufficiently strong to thrive with less shelter in the more genial weather which will doubtless then prevail.

Bury St. Edmunds, April 24th.

D. T. FISHER.

**Vine Leaf Excrecences.**—The under-sides of my Vine leaves seem to get gradually covered over with very fine blisters, which after a little time turn black, giving the leaf a speckled appearance. The black spots enlarge and unite, and the leaf turns yellowish. The disease is spreading over the whole vinery, consisting of Muscats and Hamburgs. The fruit is setting, and I am beginning to entertain fears as regards its maturity. The Vines are planted in an outside border.—J., *Guernsey*. [When the leaves in question reached us, they were so dried up that it was difficult to make out whether insects or some chill as regards the roots was the cause of the blistering. Sometimes leaves of strong healthy Vines show such spots; but they do not spread or join together like those on the leaves sent, nor do they affect the fruit. If the cause is thrips, which often get a lodgment on Vine leaves through Indian Azaleas or other plants being kept in vineries, fumigation and frequent syringings must be resorted to as soon as the young berries get about the size of small Peas. If the Vine mildew or oidium is the cause of the mischief, it will be easily recognised by its flowery dust and peculiar smell, and in that case the foliage and bunches must be dusted over with flowers of sulphur till the evil is conquered. As, however, the Vines are planted outside, some chill or check may have affected the leaves, and as the season is now setting in warm, if that is the cause, healthy young leaves will soon appear on the young shoots and laterals, which will mature the crop properly.—WILLIAM TILLERY, *Wellesbeck*.]

**Adopted Fruits.**—The following fruits have, after trial, been adopted by the Pomological Congress of France:—Apricots: Liliand and Mexico. Cherries: May Duke, Short-stalked Guigne d'Oullins, Guigne luisant, Large Black Heart, Black Tartarian. Figs: Moussonne, White Marseilles, Peau dure, Verdale. Peaches: Gabonais tardive, Précoce de Halls, Early Anne, Royale de Picmont, Early York. Pears: Beurré Delanoy, Clapp's Favourite, Senateur Vaisse, Souvenir d'Hortolés père. Apples: Baldwin, Champ Gaillard, Caroly, La-grange. Plum: Prune de Montbriand. Grapes (table): Chairet Blanche, Clairette rose, Muscat camina-la, Early White Frontignan, Muscat Salomon, Sultanich, Trebbiano. Grapes (wine): Black Cluster, Etraire de la Duy, Pelsau or Petite Etraire, Trebbiano.

## THE LIBRARY.

### LES PLANTES BULBEUSES.\*

In these two volumes of M. Bossin we recognise one of those excellent practical works in which French horticultural literature abounds. Written, not for the botanist, but for the gardener, it makes no pretensions to scientific arrangement, but simply presents, in alphabetical order, the various subjects of which it treats. It comprises the bulbous plants of the Amaryllidaceæ and Liliaceæ only, the author having, for some reason or other, thought fit to exclude the family of Iridaceæ, in which the Gladioli, Ixias, &c., have certainly as much claim to be considered bulbous plants as the Tritomas, which he admits among the Liliaceæ. We, consequently, find no account of many lovely plants usually termed bulbous, such as Anomatheca, Tritonia, Schizostylis, Tigridia, Trichonema, &c., not to mention the Crocuses and Colchicums. We trust, however, that it is the author's intention to treat of these in a succeeding volume. In the present work, the manner in which the Hyacinths, Lilies, and Tulips are dealt with is particularly deserving of notice. Each article is complete in its enumeration of species, its descriptions, and, above all, in its

which may catch the drained-off water, and convey it into a vessel prepared for its reception. This is important, as both carpet and furniture would inevitably be spoiled without it, since it is frequently difficult or impossible to remove the plants for watering without injury. To fit a zinc tray to a trough or box of this description is a very simple and easy matter. We will suppose the box to be 8 inches wide, and 1 feet in length. A piece of zinc (that known as No. 13 thickness will answer perfectly) should be provided, 4 feet 4 inches in length, and 12 inches wide. This will allow of the edges being turned up 2 inches on each side. The size of the bottom of the box should be marked out on this, and these lines should be scratched in (not too deeply) with a knife or blunt chisel; these lines will leave four squares at the angles, which must be cut out. The edges must then be turned up so as to form a tray, which should be fitted into the box before soldering. After this the angles should be soldered up, which may be effected by first damping, by means of a feather, each angle for about half an inch on each side with muriatic acid or spirits of salt. The solder being melted with the soldering-iron, or copper-bit, as it is technically termed, the edges will speedily become united, and a watertight tray will be formed. In this, near one end, should in like manner be soldered a short piece of lead or zinc pipe,

Rustic Fern Case.

cultural instructions, to which M. Bossin's long experience gives an especial value. But, while these three genera are treated of at very great length, sufficient attention has also been given to all the other subjects, and we are much pleased to add to our shelves what we consider an exceedingly valuable book of reference.

### THE POPULAR RECREATOR.†

THE second part of this publication well sustains the interest created by the appearance of the first, and contains, in addition to general matters of recreation, an essay on "Window Gardening." In this we find the following instructions respecting the fitting-up of window boxes with zinc trays:

The only modification of flower-boxes necessary, when they are to be employed indoors, consists in placing a tin or zinc tray at the bottom,

which should be passed through the wooden bottom of the box, and which will serve for the escape of the water. It is an improvement if a small tap, such as those used for gas fittings, be applied to the end of this pipe, but it is not essential. Slips of wood, upon which the pots should stand, should be laid upon the bottom of the zinc tray. Of course, in order to facilitate the outflow of the water, the boxes should be fixed slightly lower at the end where the pipe is placed; and before the plants are watered, a pail or other suitable vessel should be so arranged under the pipe as to catch the waste. This is a very cleanly method of procedure, and should always be adopted.

In this chapter the formation of Fern-cases is described at some length, with appropriate illustrations, of which we give the accompanying as a specimen.

\* Les Plantes Bulbeuses: Espèces, Races, et Variétés Cultivées dans les Jardins de l'Europe: avec l'Indication des Procédés de Culture. Par M. BOSSIN. PARIS: Librairie Agricole de la Maison Rustique, 26, Rue Jacob, 1872.

† "The Popular Recreator." Cassell, Petter, & Galpin.

THE grandest forest, says an American paper, of Pine lumber in California, containing white, yellow, and sugar Pine, Cypress, Arbor vitae, and other trees valuable for timber, lies between Susan Valley and Pitt River.

## THE INDOOR GARDEN.

### THE BEST FUCHSIAS CLASSIFIED.

THE following notes on Fuchsias were made on a collection of young plants, flowered in the gardens of the Royal Horticultural Society at Chiswick in comparatively small pots, and fairly showing the natural habit and peculiarities of the several varieties. At the time they were examined by the Floral Committee they were in a free healthy condition of growth and abundantly flowered, so that it may be presumed a fair estimate of their respective merits was arrived at. In the subjoined Report an attempt has been made to group them in such a manner as to convey a tolerably accurate notion of their colours. The three asterisks (\*\*\*) indicate the highest degree of excellence, two (\*\*) the second, and one (\*) the third, all other kinds being omitted.

#### WHITE CALYX, ROSY-PURPLE COROLLA.

\*\*\*FAIREST OF THE FAIR.—Habit free, dwarf, and drooping. Flowers medium size; tube  $\frac{3}{4}$  inch long, bulged; sepals  $\frac{1}{2}$  inch long, recurved, green at the tip; corolla  $\frac{1}{2}$  inch long, clear rosy purple, paler at the base.

\*\*ROSE OF CASTILE.—Habit stiff, compact, profuse-flowering. Flowers medium size; tube  $\frac{1}{2}$  inch long, bulged; sepals  $\frac{1}{2}$  inch long, spreading, green at the tip; corolla  $\frac{1}{2}$  inch long, clear rosy purple, with white feather at base. Still a useful decorative variety.

#### WHITE CALYX, LAKE COROLLA.

\*\*\*DELIGHT.—Habit drooping, free. Flowers medium size; tube scarcely  $\frac{1}{2}$  inch, bulged; sepals  $1\frac{1}{2}$  inch, spreading; corolla  $\frac{1}{2}$  inch, conical, deep lake, with whitish base. An improvement on Duchess of Lancaster.

\*\*LADY HEYTESBURY.—Habit free and good. Flowers medium size; tube  $\frac{3}{4}$  inch, slender, tapered downwards; sepals 1 inch, somewhat reflexed; corolla  $\frac{1}{2}$  inch, deep lake, with white feather at base.

\*\*\*STARLIGHT.—Habit good, free-blooming. Flowers medium size; tube  $\frac{3}{4}$  inch, thickest upwards; sepals  $\frac{1}{2}$  inch, spreading, faintly blushed, green at the tip; corolla  $\frac{1}{2}$  inch, very clear and pure lake. An excellent sort.

#### WHITE CALYX, ROSY CARMINE COROLLA.

\*\*\*ANNE BOLEYN.—Habit dwarf, free, drooping. Flowers medium size; tube  $\frac{1}{2}$  inch, very thick, and bulged at the base; sepals somewhat spreading, bluish, green at the tip; corolla  $\frac{1}{2}$  inch, full, deep rosy carmine, with paler flame at the base. A very elegant variety.

\*\*ARABELLA (ATTRACTION, MRS. MARSHALL).—Habit free. Flowers medium size; tube 1 inch; sepals  $1\frac{1}{2}$  inch, spreading; corolla  $\frac{3}{4}$  inch, compact, deep rosy carmine. The varieties grown under the names given as synonyms were considered to be identical with this, which is superior to Arabella Improved, the latter being coarser in habit. A good market flower.

#### WHITE CALYX, BRIGHT RED COROLLA.

\*\*CHERUB.—Habit good, free-blooming. Flowers medium size; tube  $\frac{3}{4}$  inch; sepals 1 inch, pale bluish, spreading; corolla  $\frac{1}{2}$  inch, compact, bright red. A useful variety.

\*JOSEPHINE.—Habit dwarf and free. Flowers medium size; tube  $\frac{1}{2}$  inch, bulged; sepals  $\frac{1}{2}$  inch, bluish, green-tipped; corolla  $\frac{1}{2}$  inch, spreading, carmine-red. A showy decorative plant.

#### SCARLET CALYX, DOUBLE WHITE COROLLA.

\*\*\*ENCHANTRESS.—Habit good. Flowers medium size; tube  $\frac{1}{2}$  inch, slender; sepals  $\frac{1}{2}$  inch, broad, somewhat deflexed; corolla full and even, pure white. Bold and very handsome.

\*\*VAINQUEUR DE PLEBLA.—A model as to habit. Flowers medium size; tube  $\frac{1}{2}$  inch, slender; sepals  $\frac{1}{2}$  inch, broad; corolla white, veined with red, full. A fine decorative variety.

#### SCARLET CALYX, SINGLE WHITE COROLLA.

\*\*CONSPICUA.—Habit stiff. Flowers large; tube rather over  $\frac{3}{4}$  inch, bulged; sepals 1 $\frac{1}{2}$  inch, spreading, broadish; corolla  $\frac{3}{4}$  inch, somewhat expanded, white, with scarlet feather at the base.

\*\*\*PERTANI.—Habit dwarf, drooping, and elegant. Flowers medium size; tube  $\frac{1}{2}$  inch, bulged; sepals  $\frac{1}{2}$  inch, spreading; corolla  $\frac{1}{2}$  inch, full, even, white, with rosy-scarlet feathery veins. A fine variety.

\*\*\*PURSUIT.—Habit free and elegant. Flowers medium size; tube scarcely  $\frac{1}{2}$  inch; sepals 1 inch, scarcely spreading; corolla  $\frac{1}{2}$  inch, somewhat expanded, white, with conspicuous rosy-scarlet veins. One of the best.

#### SCARLET CALYX, DOUBLE PURPLE COROLLA.

\*\*\*AVALANCHE.—Habit good and free. Flowers large; tube  $\frac{3}{4}$  inch, tapered from the base, slender; sepals  $\frac{1}{2}$  inch long,  $\frac{1}{2}$  inch broad, deflexed; corolla  $\frac{1}{2}$  inch deep, full and even, dark violet-purple. A fine, bold variety.

\*\*\*MARKSMAN.—Habit dwarf and free. Flowers medium size; tube  $\frac{1}{2}$  inch, slender; sepals  $\frac{1}{2}$  inch, broad, spreading; corolla  $\frac{3}{4}$  inch, spreading, regular, violet-purple, reddish towards the base. A most useful market sort, which never seeds.

\*\*\*PURPLE PRINCE.—Habit dwarf and free. Flowers large; tube  $\frac{1}{2}$  inch, bulged; sepals  $\frac{1}{2}$  inch, concave and deflexed as in Globosa; corolla  $\frac{1}{2}$  inch long,  $1\frac{1}{2}$  inch broad, shallow, but much expanded, regular, reddish violet. A large, showy, but rough flower; good for decorative purposes.

\*\*ALLIANCE.—Habit neat and dwarf. Flowers large; tube fully  $\frac{3}{4}$  inch; sepals 1 inch, reflexed; corolla  $\frac{1}{2}$  inch, compact, full, light reddish violet, with a red base. A very neat flower.

\*\*EXTRAORDINARY.—Habit very free. Flowers small; tube  $\frac{1}{2}$  inch, tapered upwards; sepals  $\frac{1}{2}$  inch, close, concave, deflexed; corolla about  $\frac{1}{2}$  inch, compact, deep violet-purple. Like a double form of Globosa.

#### SCARLET CALYX, MAROON COROLLA.

\*\*\*NOBLESSE.—Habit good and free. Flowers medium size; tube about  $\frac{1}{2}$  inch, slender; sepals  $\frac{1}{2}$  inch, spreading, bright crimson-scarlet; corolla  $\frac{1}{2}$  inch, prominent, rich maroon, flushed and veined towards the base with red. A very fine Fuchsia.

#### SCARLET CALYX, DARK VIOLET-PURPLE COROLLA.

\*\*\*WEeping BEAUTY.—Habit dwarf, free, and good. Flowers medium size; tube nearly  $\frac{3}{4}$  inch, rather bulged; sepals 1 inch, broadish, bright crimson-scarlet; corolla  $\frac{3}{4}$  inch, moderately expanded, rich deep purple. A very fine Fuchsia.

\*\*CROWN PRINCE OF PRUSSIA.—Habit dwarf and free. Flowers rather large; tube  $\frac{1}{2}$  inch, bulged; sepals  $\frac{1}{2}$  inch, broad; corolla  $\frac{1}{2}$  inch, prominent, dark purple, reddish at the base.

\*\*INDIVISIBLE.—Habit dwarf and free. Flowers medium size; tube  $\frac{3}{4}$  inch; sepals 1 inch, spreading; corolla  $\frac{1}{2}$  inch, somewhat expanded, violet-purple, reddish at the base. A good useful variety.

#### SCARLET CALYX, REDDISH-PURPLE COROLLA.

\*\*\*KING OF THE FUCHSIAS.—Neat and dwarf in habit, and a free bloomer. Flowers medium size; tube  $\frac{3}{4}$  inch, stoutish; sepals 1 inch, broad, spreading; corolla  $\frac{1}{2}$  inch, prominent, rather spreading, reddish-purple. A distinct-looking and desirable variety.

\*\*FIRST OF THE DAY.—Dwarf, neat, and free-blooming. Flowers medium size; tube scarcely  $\frac{1}{2}$  inch; sepals  $\frac{1}{2}$  inch, reflexed; corolla  $\frac{1}{2}$  inch, light reddish-purple, redder towards the base. A good variety for growing in the form of small plants.

#### SCARLET CALYX, LAKE-RED COROLLA.

\*\*\*COMMANDER.—Habit good. Flowers large; tube  $\frac{3}{4}$  inch, stoutish; sepals  $1\frac{1}{2}$  inch, spreading; corolla about 1 inch, conical, light lake-red. A bold handsome flower, and showy as a pot plant.—*Thomas Moore, in the Journal of the Royal Horticultural Society.*

## POINSETTIA PULCHERRIMA.

THIS deservedly favourite winter-flowering plant is too well known to require description. It may not, however, be so generally known that it may be induced to flower a second time, *i.e.* twice during the same season, and that it may be had in that condition up to the month of May, or even later. I have sent you some bracts gathered from plants in 6-inch pots that flowered the first time during December and January. After they had done blooming, they were cut down to within an inch or two of the surface of the soil in the pots. They were still kept in heat, and the intention was to grow them on in order to produce early bracts for cutting, &c., during the early part of next winter. They soon produced shoots which bore beautiful floral leaves when two, or not in any instance more than three, inches long, but no green foliage. These red leaves or bracts developed themselves about the middle or during the last week of March, and the plants have continued in much the same state up to the present time (May 3rd). Their appearance is certainly remarkable, as they have produced no normal or green foliage whatever; on the contrary, they are lovely little bushes of intense scarlet. The plants were struck from eyes in February 1872, in the same way in which Vines are usually propagated. They were kept in a cool pit during the summer months, and as has already been said, they flowered the first time during the months of December and January. I am inclined to ascribe their flowering so promptly the second time to the circumstance of their being cut back so early in the season—about the beginning of February. But as to whether a similar result may (or may not) be hereafter produced by plants treated in this way I am as yet unable to say; the thing is, however, worthy of a trial.

*Colford, Bury St. Edmunds.*

[The bracts or floral leaves that accompanied this communication were of good size and beautifully coloured.]

P. G.

## MOISTENING CORK FERNERIES.

IN reference to virgin cork as a material for Ferneries under glass, I have long since come to the conclusion that it is, without exception, one of the worst materials in regard to porosity that we can make use of. I quite agree as to its artistic effect, the great objection with me has been that it is impossible to keep it moist without a large amount of attention in regard to watering. Supposing it were watered three times a day, so little is its porosity, that towards evening it would become perfectly dry. With respect to the remedy, it is as follows:—I suspend from the roof some half dozen half-pint bottles, filled with water, and adapting a few strands of lamp cotton, leave the long end hanging over the neck of the bottles, so as to act as a syphon and allow the drops to fall upon a piece of flat Moss, which has been tacked on to the cork. The bottles require attention only once in two or three days, and the result is that I am enabled in this way to keep moisture in the cork. It is important, however, that the cork should have a thorough syringing before com-

Mode of moistening Cork Ferneries.

mencing with the bottles. The latter need not be in any degree unsightly, as it is a simple matter to place a piece of cork in front of them in such a way that they are entirely hidden.

283, Clapham Road.

WILLIAM SOPER.

## NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Myrtus tenuifolia.**—This uncommon species of Myrtle deserves general culture, on account of its graceful habit. Allowed to droop downwards it is very suitable for a vase, or for placing on a pedestal.—H.

**Rivina humilis.**—This plant, common in our stoves and easily known by its racemes of bright coral-coloured berries, looks very well planted out against a back wall of a stove, and bears its berries throughout the year in such a position.—V. H.

**Tacsonia Van Volkemii** as a Winter Bloomer.—In the conservatory at St. Leonards, near Maidstone, there is a plant of this now sending down its exquisite parasol-like flowers, from the horizontal bars and rafters. The gardener there informed us that it has been flowering all through the past autumn and winter in like manner. This quality of winter-blooming, in addition to its unique beauty, ought surely to give it the first place among conservatory climbers.

**Nægelia Margarita.**—This is a hybrid between *N. amabilis* and *N. alba* Lutescens, raised by M. Desmoulins, gardener to M. Linder, of L'Isle-Adam. It is perhaps the very finest of the white-flowered Nægelias, and as it continues in bloom all through the winter, it forms during that season one of the most attractive ornaments of the warm house or stove. The leaves and stem are of a pale green or slightly ferruginous colour, but not zoned or striped with red as in many of the species; and the flowers are large, pure white, pendent, and disposed in a compact conical spike of very pleasing appearance.

**Plant Tubs.**—Can you inform me whether or not tubs for plants, such as are figured in Macintosh's "Book of the Garden," vol. ii., p. 682, are made or sold now, as they are the best I have seen as yet?—C. R.—[We do not think such tubs are anywhere kept in stock; but any carpenter could readily make them. They are square, and wider at the top than at the bottom; two of the sides are fixed by means of two iron studs let into the bottom framework, and their upper part is secured to the other two sides by iron bands, which, being lifted up, allow the two opposite sides to fold down, these being hinged to the bottom frame.]

## THE GARDEN GUIDE.

KENT.

## LINTON PARK.

LOOKING southwards over the Weald of Kent, and embosomed in groves of evergreen trees, Linton Gardens are attractive at all seasons; but at none more so than on this sunny May morning, when all the hollows are silvered with Ladies' Smocks, and the large cups opened on the standard Magnolias. Among the most interesting gardens in the kingdom, Linton is chiefly remarkable for its trees, particularly Pines, many of which are very fine specimens: among them, the Monterey Pine (*P. insignis*) is 65 feet high, the Austrian Pine 55 feet, the Swiss Pine (*P. Cembra*) 55 feet, the Yellow Pine (*P. Ponderosa*) 55 feet, the Bhotan Pine (*P. excelsa*) 11 feet, Webb's Silver Fir (*Picea Webbiana*) 37 feet, *P. lasiocarpa* 17 feet, *P. Pinsapo* 14 feet, a *P. cephalonica* 50 feet. The Redwood (*Taxodium sempervirens*) is 37 feet high, an *Arucaria imbricata* 31 feet, a Deodar 49 feet, Lambert's Cypress 45 feet, the Giant Thuja (*T. gigantea*, commonly known as *P. Lobbi*) 35 feet, and the Nutka Sound Cypress (*Cupressus Nutkaensis*) 23 feet. A Cork tree here is one of the finest things in the country, being 9 feet round the waist, the cork very thick and rugged, and the shoots all with a weeping tendency, like those of some of the evergreen Oaks in California. Worthy of association with this is a Tulip tree 11 feet in girth, and remarkable for sending forth huge branches horizontally and near the ground, which is not the usual habit of the tree. There is an avenue of Wellingtonias: this tree is not so remarkable for size here as some of those previously named. The evergreen Magnolia (*M. grandiflora*) thrives as a standard, and trained, up the columns of the house, grows 30 feet high, its fine glistening foliage beautifully adorning the front of the mansion. There is a picturesque cool fernery, laid out by Mr. Blake in his best manner, and a large and handsome conservatory. The terrace is a pleasing one—and is called for by the nature of the ground, sloping, as it does, rapidly down to the Weald; and the view it commands is extensive and pleasing. The effect of the south front of the house is charming, from its being freely adorned with climbers. Camellias do well in the open air away from walls. There is a fine avenue of mixed trees approaching the house; also two of Elms, of good size. There is not the vast spread of glass here that one looks for in large places now-a-days; but Pines and Vines are well done. The park is prettily varied—open in the centre, and with its boundary well concealed; but somewhat disfigured by a small dot of water. Bedding out is extensively carried out here, though not so much as it used to be. Altogether, the garden is most instructive and interesting. It contains quite a model of a gardener's house. To other important features of this garden special allusion will be made hereafter. The above measurements of trees were made last September.—Viscount Holmesdale\* (gardener, Mr. J. Robson), Maidstone.

## HUNTON COURT.

Not a large, but a pretty garden, containing a good specimen of an unusually large variegated Elm, which is sometimes almost white in summer, but varies considerably in this respect from season to season. There is also an unusually good deciduous Cypress; pretty Ivy borders and baskets, interesting mixed borders, and a fair fruit and kitchen garden, but little glass. In the churchyard close by, there is a fine old Yew more than 16 feet round.—Mrs. Bannerman (gardener Mr. Goddard), Maidstone.

## LOOSE CHURCHYARD (near Maidstone).

Here is a very remarkable Yew. Measured twenty years ago, by Mr. Robson, of Linton, it was 32 feet 10 inches in circumference round the narrowest part of the waist. It is now so surrounded by a close ugly paling that measuring it or even seeing the grand bole readily is out of the question. One of the branches is as large as many Yew trees considered to be giants of their kind. The head is quite healthy, and the spread of branches (measured on the 2nd May, 1873) about 63 feet in diameter.

## EAST SUTTON.

There are fair kitchen and fruit gardens here, and well handled trees of bush Apples and pyramidal Pears. There are also well covered walls, and some fair fruit houses and glass cases. The park is much varied in surface, and commands extensive views over the Weald of Kent. It is thickly wooded, and contains some unusually good groups of Oak, Ash, Elm, and Chestnut trees. Conifers seem to thrive, though few specimens are to be seen.—Sir E. Filmer (gardener Mr. Skinner), Maidstone.

\* In these brief notices of some of our more instructive gardens, we propose to give the proprietor's name and that of the gardener, together with the nearest town or village from which the places mentioned can be most conveniently reached.

## MAIDSTONE CEMETERY.

This is a large and creditably kept cemetery, and has been freely planted with Pines and other evergreens during the past fourteen years. An avenue of Austrian Pines looks so well as to make us ask if we are not wrong in ignoring the claims of this while planting abundantly such things as the Wellingtonia and Araucaria, almost sure to fail as avenues. Although young, the avenue of Austrians here is most imposing. It is much to be desired that tasteful grouping of trees in cemeteries would take the place of the promiscuous dotting which is now the rule.

## ORCHARDS IN THE MAIDSTONE DISTRICT.

The country hereabouts is to a great extent a fruit garden, or rather a fruit farm. Cherries, Filberts, Plums, and Apples are the fruits mostly grown. The Cherry-orchards predominate, and are very lovely late in April or early in May. Earth, wild or cultivated, has few things more fair to show than a Kentish Cherry-orchard in full blossom, the fresh green Grass beneath the trees being whitened with the snowy blooms falling in gentle showers, and the sheep grazing quietly around. The Filbert is abundantly grown as a large close-pruned basket-tree, frequently planted beneath the taller orchard-trees. It is greatly to be regretted that the orchard is a feature so often absent from the country seat in most parts of Britain. Well planted and managed nothing is more beautiful or profitable; and surely it would be well to add to the usually poor supplies obtained from standard trees in the kitchen garden, &c., by creating in every place where there is room enough an orchard of trees, the fruit of which may be depended upon to attain perfection in the district in which they are planted.

## PRESTON HALL.

A large, well-designed and well-kept garden, rich in varied interest, the mansion finely situated in an undulating park, sloping down to the valley of the Medway, and with excellent views. The design of the garden is far above the average of merit in this way, and only marred by some feeble lines of standard Roses. The terrace garden is good and not over large. There are fair specimens of Pines and groups of Horse Chestnut and Elm, of each tree of which there are specimens 22 feet round the waist. There are good fruit houses and glass walls, and the fruit and kitchen gardens are neatly kept and well cultivated. Here is the best orchard I have ever seen in a private place. If gardeners generally could see this, no doubt our fruit rooms would one day be better filled than they are nowadays from the little spaces stolen for fruit trees from the kitchen garden. A plan and description of this orchard is being prepared for THE GARDEN. The fruit-room, offices, &c., are excellent, and Preston Hall gardens are in all respects beautiful and instructive, whether looked at from the point of view of landscape gardening, good keeping, or cultivation.—H. A. Brassey, Esq. (gardener, Mr. W. Bradley), Maidstone.

## LEYBOURNE GRANGE.

Situated in a wide and beautiful park, in many parts well planted. The fruit and kitchen gardens here are good, and there is an excellent glass wall, the cultivation generally being of the best kind. Plant culture has been given up for that of fruit, and the large conservatory is planted with Vines. There is a pretty Grass orchard, in which is a Bigarreau Cherry 60 feet in the diameter of its branches, and looking, in bloom, this 14th day of May, more like a Cedar snowed over than a Cherry tree. The best trees in the park are Elms. In a wood there is a curious "Siamese Twin" Elm. Two Elms grow tall and erect, 2 feet apart; 7 feet above the ground an immense branch about 2½ feet deep passes from one to the other, the trees above this juncture not having any remarkable features. The black American Spruce is extensively planted in the woods instead of the common Spruce, which fails here; and there are long avenues in the woods margined by the always robust and vigorous Austrian Pine.—Sir J. Hawley (gardener, Mr. Bowman), Maidstone.

## ST. LEONARD'S.

The house, on a rising bluff, pleasantly overlooks a piece of well-managed river-like water and some pretty park ground beyond it. There is a compact and well-kept kitchen garden and good orchard, a range of glass devoted to fruit and plant culture, a pretty small flower garden and a conservatory with one end tastefully arranged with Ferns in the natural style. *Dracena indivisa* grows freely in the open air here, though occasionally a severe winter hurts it. Even then, however, it springs again from the ground.—Mrs. Savage (gardener, Mr. Henderson), Maidstone.

## MEREWORTH.

There is a good kitchen and fair fruit garden here, and an excellent series of fruit and forcing houses, in which the best cultivation may be seen. Peaches are unusually well grown in the houses. The flower garden, which surrounds the house on three sides, is an over-

elaborated one, embellished with the pounded red brick rubbish which seems somewhat popular in the gardens of Kent, judging by the gardens near Maidstone. The park is boldly varied, but is not remarkable for trees or planting. A fine glossy tuft of Mistletoe, 4 feet or more deep, and a yard through, hangs from a rather young tree of the common Acacia, near the house.—Lord Falmouth (gardener, Mr. Horton), Maidstone.

In the village of Mereworth, in the cottage-garden of Mr. Sudds, there is a Yew tree which seems the only worthy relic I have ever seen of the best days of the art of the topiarist. It is clipped into five perfect tiers, and above that waves a free-headed tree, probably about 40 feet high. By far the best and most striking example of a clipped Yew in this part of the country; it is, though verdant and vigorous, an old tree.

R.

## PUBLIC GARDENS.

## THE BOIS DE BOULOGNE.

FEW parks or public gardens offer a finer example of improvement or design than this. How we improve by friction! Till 1852 the Bois was virtually a forest; but Napoleon III., in his admiration for English parks, determined to add their charms to Paris, or rather to improve upon them, and the Bois is one result. As a combination of wild wood and noble pleasure-garden it is magnificent. The Bois de Boulogne contains more than 2,000 acres, of which nearly half is wood, a quarter grass, one-eighth roads, and more than 70 acres water. It has more than the beauty and finish of any London park in some spots, but, on the other hand, vast spreads of it are covered with a thick, small, and somewhat scrub-like wood, in which wild flowers grow abundantly. The planting on and near the islands is far superior to anything to be witnessed in our own parks. There are some of the finest views here ever seen in a public park—the water in one direction looking like an interminable inlet, beautifully fringed with shrubs and trees, while in another several charming views are opened up, showing the hilly suburban country towards Boulogne, St. Cloud, and that neighbourhood. There is some bold rockwork attempted and well done about the artificial water; and very creditable pains are taken to make the vegetation along it diversified in character, so that at one place you meet Conifers, at another rock shrubs, in another Magnolias, and so on; without the eternal repetition of common things which one too often sees at home. At Longchamps there is a large and ambitious cascade. Above the spring or shoot of the cascade is an arch of rustic rocks, over which fall Ivy and rock shrubs, the whole being backed with a healthy rising plantation; but, although made at great expense, this cascade cannot be pronounced a happy one. The fault of the most frequented part of the Bois de Boulogne is that the banks which fall to the water are in some parts a little too suggestive of a railway embankment, and display but little of that indefiniteness of gradation and outline which we find in the true examples of the natural style of laying out grounds. But you do not notice this from the position above described, from whence indeed the scene is charming. The fault just hinted at is common to almost every example of this style to be seen about Paris; and in most of their walks, mounds, and the turnings of their streams, you can detect a family likeness and a style of curvature which is certainly never exhibited by nature.

Apart from the perfect keeping of the whole, the chief lesson to be learnt here by the English planter is the value of paying far greater attention than we at present do to the artistic planting of choice hardy trees and shrubs. The islands seen from the margin of the lakes are at all times beautiful, in consequence of the presence of a varied collection of the finest shrubs and trees tastefully disposed. They show at a glance the immense superiority of permanent embellishment over fleeting annual display. The planting of these islands was expensive at first, and required a good knowledge of trees and shrubs, besides a large amount of taste in the designer; but it is so done that were the hand of man to be removed from them for half a century they would not suffer in the least. Nothing could be easier than to find examples of gardens quite as costly in the first instance, which, while involving a yearly expenditure, would be ruined by a year's neglect. It is summer, and along the margins of these islands

you see the fresh pyramids of the deciduous Cypress starting from graceful surroundings of hardy Bamboos and Pampas Grass, and, far beyond, a group of bright silvery Negundo in the midst of dark-green vegetation, with scores of tints and

conspicuous at long distances through the other trees. In autumn the variety and richness of the tints of the foliage offer a varied picture from week to week; and in winter the many picturesque and graceful forms of the deciduous trees

PLAN OF THE BOIS DE BOULOGNE

types of tree-form around. It is spring, and the whole scene is animated by the cheerful flush of bloom of the many shrubs that burst into blossom with the strengthening sun, and, while the Oaks are yet leafless, the large swollen flower-buds of the splendid deciduous Magnolias may be seen

among the evergreen shrubs and Pines offer to the observant eye as much interest as at any other season. The Bois suffered to a fearful extent during the war, but the French, with their wonderful powers of recovery, so to say, will soon restore its old glories.

## THE FLOWER GARDEN.

### NEW, RARE, OR NEGLECTED ALPINE PLANTS.

(Concluded from page 333.)

**PRIMULA ALTAICA** (Altaian Primrose).—Among the choicest gems of the hardy spring garden there are few that will bear comparison with this, and yet there are few gardens where it is to be found. In general appearance it very closely resembles our own *P. acaulis* (*volgaris*), but may at once be distinguished by its narrow and more deeply-cleft petals, the reddish hue of its flower-stalks, and its singularly attenuated, deeply channelled, and sharply cuspidated calyx, the basis of which is not nearly so deflexed as in *P. acaulis*. The tube of the corolla, too, rises higher above the calyx than in the last-named species. The flowers, which are produced in great profusion—quite smothering the plant when it is in a healthy state—are of the most lovely soft mauve, the base sulphur, with an orange spot in the centre. It comes into bloom several weeks earlier than the common Primrose; in fact, it is the companion of the earliest Aconites, Snowdrops, and Snowflakes. It seems to come quite true from seed, but is very shy in ripening any. It may be grown either in the rock-garden, or the choice mixed border, in moist, deep, sandy loam.

**PRIMULA JAPONICA** (Japanese Primrose).—A very noble and perfectly hardy species, recently introduced from Japan, and not inaptly named the "King of the Primulas." Its flower-stems rise from 1 to 2½ feet in height, and in the month of May begin to exhibit the brilliant magenta or deep purplish-erimson flowers, which are very numerous, and arranged in from three to six whorls on the top of the stem, each flower being from 1 to 1½ inch across. The leaves resemble those of *P. denticulata*, and are from 6 to 10 inches long and 3 to 4½ inches broad, forming a rosette 1½ foot, or more, across. If planted in the rock-garden, it should not be among minute alpine species, but grouped with subjects growing a foot or more high, and in sheltered positions, where its fine foliage would not be injured by harsh winds. It is a magnificent plant for a warm sheltered border, or for a position among dwarf shrubs, in sandy loam and leaf-mould. Propagated from seed, which it yields freely. The seed should be sown in light soil mixed with silver sand, in pans placed in cold frames, where they should be allowed to remain until it germinates. Two years may elapse before the young plants appear. Many persons, ignorant of this, have thrown out the contents of their seed-pans in despair, because no sign of germination appeared during the first year, and a great deal of good seed has doubtless been lost in this way. Another cause of failure is placing the seed-pans in heat; they should be kept cool. After the young plants are pricked off and potted, they are sometimes benefited by a little heat, just to start them afresh; but they must afterwards be carefully hardened off.

**PRIMULA PARRYI** (Parry's Primula).—This Primula is spoken of by American botanists as the finest of all the alpine of the Rocky Mountains. It grows from 9 to 12 inches high, and flowers from April to June, bearing heads of the richest purple blossoms. The leaves are erect, and resemble those of *P. longiflora* on a large scale. It requires an abundance of moisture, as in its native habitats it occurs "in shallow streams springing from the melting snows at an elevation of 7,000 feet or more." This fine species has only recently been reintroduced into this country by Messrs. Backhouse and Son, York.

**RHODODENDRON FLEXOSUM** (Early Rhododendron).—In this we have a perfect gem for the rock-garden, the margins of choice dwarf beds of American plants, or any position in which a very beautiful dwarf shrub may be desired. It is a hybrid between the very early-blooming *R. dauricum atro-vivaceum* and the fine *R. ciliatum*, and has the very early-flowering habit of the former with the large and handsome blooms of the latter. It is frequently in full bloom early in March. The leaves are dark green, shining, oval, and slightly ciliated; the flowers, within an eighth or so of 2 inches across, of the most delicate satiny lilac, unmarked by splottings of any kind, and abundantly produced on the compact little bushes. It is a worthy companion to the Dog's-tooth Violet, the Siberian

Squill, and *Sisyrinchium grandiflorum*, which are in full beauty at the same time.

**SAPONARIA CESPITOSA** (Tufted Soapwort).—A neat, dense-habited species from the Pyrenees, forming very rigid tufts like those of *Silene acaulis*, but much more robust, and bearing sub-umbellate heads of showy rose-coloured flowers, which first appear in June. It should be planted in deep loam, mixed with gravel and sand, in sunny fissures of rockwork.

**SISYRINCHIUM GRANDIFLOREM** (Spring Satin-flower).—A beautiful early spring-flowering perennial, 6 to 10 inches high. The flowers are of a rich deep purple, with red style and filaments, and yellow anthers (or pure white, with transparent style and white filaments), issuing from a two-flowered spathe with a thin transparent margin. The leaves are narrow, sword-shaped, and sheathing at the base. A native of the N.W. regions of N. America. Suitable either for the rock-garden or for borders, in light peaty soil or very sandy loam, and in warm positions. It is also a charming subject for growing in pots in cold frames, from which it may be removed to the greenhouse when in flower in early spring. Multiplied by careful division.

**UMBELICUS SPINOSUS** (Spiny Umbilicus).—A very singular looking plant, with somewhat the appearance of a small *Apera* or *Haworthia*. The root-leaves are oblong in shape, convex towards the points, and form a rosette like a *Semprevivum*, each leaf bearing a spine at the apex. The flowers, which appear early in summer, are yellow, and form a terminal cylindrical spike on the top of the flower-stem, which is furnished with flat lance-shaped leaves. A native of Siberia, China, and Japan. A good plant for the rock-garden, in dry sunny spots. It is perfectly hardy, and my friend, Mr. James Atkins, of Painswick, informs me that on his rock-work it withstood the severe weather of January and February, 1871, without the slightest injury. Its chief enemies are the slugs, which destroy it whenever they have a chance.

**WALDSTEINIA FRAGARIOIDES** (Strawberry Waldsteinia).—A showy plant from N. America, with creeping, bright-red, hairy stems. Grows about 6 inches high, and flowers in summer, when it produces numerous bright-yellow blooms about half an inch across. The leaves are ternate, on long channelled stalks, with obovate, smooth green leaflets, which fade to a lurid red. Suitable for rock-work, borders, fringes of shrubberies, &c., and thriving in ordinary soils.

**WULFENIA CARINTHIACA** (Carinthian Wulfenia).—A remarkably dwarf, almost stemless evergreen herb, 12 to 18 inches high, bearing in summer showy spikes of purplish-blue, drooping, tubular flowers, issuing on short stalks from the axils of the bracts. The leaves are oblong, narrowed at the base, doubly crenated, stalked. Found only on one or two mountains in Carinthia. A very ornamental plant for rock-work or borders, in light, moist, sandy loam.

**ZARANIA NOBILIORA** (Creeping Vervain).—A pretty and modest-looking, compactly spreading, trailing plant, with prostrate stems 2 or 3 feet or more in length. It blooms late in summer, producing small purplish flowers in small roundish heads, on long stalks springing from the axils of the leaves, which are spoon-shaped, coarsely and irregularly notched, with a wedge-shaped base, attenuated at a stalk. A native of Asia and America. Very suitable for the rougher parts of the rock-garden, or for borders or edgings, in any rather warm soil.

### WHAT IS A PRIMROSE?

I TAKE a special interest in this question, not only as a grower of this class of plants, but also because having put a literal, and as I believed, a common sense interpretation upon the Royal Horticultural Society's schedule, I felt myself precluded from entering into competition for the prizes offered for Primroses by that society this spring, simply because I had not enough of true Primroses to suit the requirements of the schedule, and I did not for a moment believe that Polyanthus would be admitted as Primroses. Now it is a curious fact, bearing on this question, that, in ordinary parlance, no one in speaking of a Primrose ever means a Polyanthus, or in ordering such from a florist would be satisfied to receive a Polyanthus instead of a Primrose. In gardening phraseology the distinction is perfectly understood; one might as soon expect to be given a Pansy for a Violet as a Polyanthus for a Primrose. Indeed in the case of the *Viola* we

find a class of plants that are commonly classified in a fashion analogous to the Primula. The term *Viola* includes all Violets, double and single, bedding Violas and Pansies, and all English and Belgian kinds, and many less known varieties. Now I maintain that, although the Primrose happens to be a section of the great Primula family, yet it would be just as absurd to term all Primulas Primroses as it would be to term all *Violas* Violets; indeed, if the schedule had contained a class for six boxes of Violets, no one would have dreamt of putting up any other class of plants than such as are strictly Violets. In all such classes there must be limitations subject to common sense definitions; and what more proper than that the ordinary and popular classification of these plants should in the interpretation of schedules have full significance? If a class for hardy Primroses is inserted in the schedule next year, let us hope that it will be so worded as to leave not a shadow of doubt on the minds of exhibitors as to what is required. I am not at all sure that a class which requires a boxful of plants of each sort is one likely to answer well in the case of Primroses. Under such a mode of showing, the commoner and easily grown kinds are always present, but how is it that the fine double purples, roses, crimsons, and yellows, are never seen staged? Simply because they are more difficult to grow, and a boxful of them is a positive rarity. A dozen sorts, three plants of each, correctly named, to be shown as may be most convenient to the exhibitor, would bring many old and new favourites in the Primrose way to South Kensington. ALEX. DEAN.

### DIAPENSIA LAPPONICA.

This sturdy dwarf little evergreen alpine shrub is rarely seen even in botanic gardens, and is usually considered impossible

*Diapensia Laponica.*

to cultivate. It may, however, be grown very well on fully exposed rockwork in deep sandy and stony peat, kept well moistened during the warm season. It grows in very dense rounded tufts, with narrow closely packed spoon-shaped leaves, and solitary white flowers with yellow stamens, about half an inch across, the whole plant being often under 2 inches high. A native of Northern Europe and North America, on high mountains or in arctic latitudes, flowering in summer, and probably most easily increased from seed, though as yet the plant has been so little grown that much cannot be said on this subject.

### HARDY CYCLAMENS.

#### GENERAL CULTURE.

PERFECT drainage at the roots is indispensable for the successful culture of all the Cyclamens, growing as they often do in their native habitats amongst stones, rocks, and *débris* of the mountains, mixed with an accumulation of vegetable soil—the tubers being thereby often covered to a considerable depth, and not exposed to the action of the atmosphere, as is too often the case under culture, by placing them on the surface of the soil. This practice is in most instances very injurious, drying up and destroying the incipient young leaf and flower-buds when the tubers are apparently at rest; for I find in most species that, though leafless, the fibres and young buds for the ensuing year are still making slow but healthy progress under

favourable circumstances. Collectors from abroad should be specially careful in this particular. We seldom find tubers of some of the species that have been much dried or exposed to the air vegetate freely, or sometimes at all. I have now by me some roots imported nearly six years since (I believe from the Greek isles), that were thus exposed, and though the tubers have remained sound and sent out tolerably healthy fibres, they have not until this season produced healthy leaves. They have made two or three abortive attempts before, but always failed. Now, having recovered vigour of foliage, I fully expect them to bloom next autumn. In *C. hederifolium* and its varieties the greater portion of their fibres issue from the upper surface and sides of the tuber, indicating without doubt the necessity of their being beneath the soil. The habit in *C. coum*, *C. vernum*, and their allies, of the leaf and flower stalks, when in a vigorous state, running beneath the soil, often to a considerable distance from the tuber, before rising to the surface, points in the same direction. Though Cyclamens require perfect drainage at the root, they like plenty of moisture above when in full vigour of growth. Cyclamens generally like a rich soil, composed of good friable loam, well-decayed vegetable matter, and cow manure, reduced to a state of mould, and rendered sweet by exposure to the atmosphere before use. *C. hederifolium* and its varieties require a stiffer loam and stronger manure than the others. They are all admirably adapted for rockwork; they enjoy warm nooks, partial shade from the mid-day sun, and shelter from the effects of drying, cutting winds. Neither of these can they bear with impunity. An eastern or south-eastern aspect is best, screened from cutting winds, as affording the requisite protection against heat; but a northern one will do well. They love an open yet sheltered spot; pure air is their delight. I have a northward piece of rockwork covered with them, which, from the end of August, when they begin to bloom, up to the end of March, when the leaves begin to die down, is much admired both for the flowers and also for the beauty of the wax-like foliage. During the dead period of winter it is in full perfection; and few things are more ornamental. Cyclamens are best propagated by seed sown as soon as it is ripe, in well-drained pots of light soil. I generally cover the surface of the soil, after sowing, with a little Moss, to ensure uniform dampness, and place them in a sheltered spot out of doors. As soon as the plants begin to appear, which may be in a month or six weeks, the Moss should be gradually removed. As soon as the first leaf is tolerably developed, they should be transplanted, about an inch apart, in seed pans of rich light earth, and encouraged to grow as long as possible, being sheltered in a cold frame, with abundance of air at all times. When the leaves have perished the following summer, the tubers may be planted out or potted, according to their strength.

**Round-leaved Cyclamen (*C. coum*).**—Tuber round, depressed, smooth, fibres issuing from one point on the under side only. Leaves of a plain dark green, cordate, slightly indented; these, with the flowers, generally spring from a short stem rising from the centre of the tuber. Corolla short, constricted at the mouth; reddish purple, darker at the mouth, where there is a white circle; inside striped red. Flowers from December to March, and is a native of the Greek Archipelago. This, with the others of the same section, viz., *vernum*, *Sweet* (*coum zonale*), *ibericum*, *Atkinsii*, and the numerous hybrids from it, though perfectly hardy, and frequently in bloom in the open ground before the Snowdrop, yet, to preserve the flowers from the effects of unfavourable weather, will be the better for slight protection, or a pit or frame devoted to them in which to plant them out. I grow many in this way, and during the early spring, from January to the middle of March, they are one sheet of bloom. When so cultivated, it is best to take out the soil, say 1½ foot to 2 feet deep, place a layer of rough stones 9 to 12 inches deep at the bottom, covering them with inverted turf to keep the soil from washing down and injuring the drainage; then fill up with soil composed of about one-third of good free loam, one-third of well-decayed leaf-mould, and one-third of thoroughly decomposed cow manure. Plant 1½ inch to 2 inches deep, and every year, soon after the leaves die down, take off the surface-dressing as far as the top of the tubers, and fresh surface them with the same compost, or in alternate years they may only have a dressing on the surface of well-decayed leaves or cow manure. During summer, or, indeed, after April, the glass is removed, and they are slightly shaded with Larch-Fir boughs (cut before the leaves expand) laid over them, to shelter from the extreme heat of the sun. As soon as they begin to appear in the autumn, gradually take these off, and do not use the glass until severe weather sets in—at all times, both day and night, admitting air at both back and front, and in fine weather draw the lights off, remembering that the plants are perfectly hardy, and soon injured if kept too close. They do not like frequent removal. *C. coum album* is a variety raised by me, which received a first-class certificate from the

Royal Horticultural Society, 1868. It has the dark, plain foliage of *comum*, with flowers white, and dark mouth; hardy; same treatment as *comum*. It is a very distinct and interesting variety, well worthy of culture. *C. Atkinsii*, a hybrid of the *comum* section, also raised by me, has larger flowers, white, with dark mouth, and nearly round or ovoid leaves, variously marked. *C. verum* of Sweet is considered by many as only a variety of *comum*, and for it I would suggest the name of *C. comum* var. *zonale* (from its marked foliage). I was for a long time unwilling to give it up as a distinct species, but now doubt there being sufficient permanent specific distinction to warrant its being retained as such, especially after seeing the many forms and hues the leaves of other species of this genus assume. Though this, as well as *C. comum*, retains its peculiarities as to markings very correctly from seed, so do some undoubted varieties of other species of *Cyclamen*. In Loddiges' "Bot. Cab." t. 108, some years previous to Sweet's publication, it is well figured as *C. comum*. There are specimens in various herbariums of this form under the name of *C. verum* (Sweet), mostly from Iberia and Tiflis.

**Iberian *Cyclamen* (*C. ibericum*).**—This also belongs to the *comum* section. I fear the original type of the species as first imported into this country is lost; the greater portion now sold as such are hybrids of the *Atkinsii* group. There is some obscurity respecting the authority for this species and its native country; but there are specimens of it in the Kew and Oxford Herbariums marked "ex Iberiâ." Leaves very various. Flowers in spring: corolla rather longer than in *comum*; mouth constricted, not toothed; colour various, from deep red-purple to rose, lilac, and white, with intensely dark mouth; and produced more abundantly than by *comum*.

**European *Cyclamen* (*C. europæum*).**—Tuber of medium size and very irregular form, sometimes roundish or depressed and knotted, at other times elongated. The rind is thin, smooth, yellowish, sometimes "scabby." The underground stem or rhizome is often of considerable length and size, sometimes even more than a foot in length. The leaves and flowers originate from stalks or branches, which emerge from all parts of the tuber. The root fibrils spring from the lower surface of the tuber as freely as from the upper, but are never so numerous as in *C. hederæfolium*; and there are usually two or three stems springing from different parts, and growing in different directions, from which the leaves and flowers arise. When these stems are much elongated and irregular, the plant becomes the *C. radice-anemone*, or *C. anemonoides* of some old authors. The leaves in this, as well as in most of the other species, vary much in outline as well as extent of the markings on the upper surface and colour beneath. Those from the more northern habitats are coarser and more decidedly dentate than those from some localities south of the Alps, where they assume in a measure the finer texture, rounder form, and more delicate markings, of *C. persicum*. The leaves appear before and with the flowers, and remain during the greater part of the year. Flowers from June to November, or, with slight protection, until the end of the year. The petals are rather short, stiff, and of a reddish-purple colour. The base or mouth of the corolla pentagonal, not dentate. Some of the southern varieties, by attention to cultivation under glass, may even assume a perpetual flowering character. The varieties *Clusii*, *littorale*, and *Peakeanum* are of this section. In these varieties the flowers become much longer, are of a more delicate colour, often approaching peach colour, and are almost the size of those of *C. persicum*. Pure white flowers are rare, but pale ones are not uncommon. They are very fragrant. Thrives freely in various parts of the country in light, loamy, well-drained soil, as a choice border and rockwork plant. Where it does not do well in ordinary soil, it should be tried in a deep bed of light loam, mingled with pieces of broken stone. In all cases it is best to cover the ground with cocoa-fibre. It is a very desirable species, on account of its delightful fragrance and long succession of flowers. I have often seen them luxuriate in the *d'Arès* of old walls, and on the mountain-side, with a very sparing quantity of vegetable earth to grow in.

**Ivy-leaved *Cyclamen* (*C. hederæfolium*).**—A native of Switzerland, South Europe, Italy, Greece and its isles, and the north coast of Africa. Tuber not infrequently a foot in diameter when full-grown; its shape is somewhat spheroidal, depressed on the upper surface, rounded beneath. It is covered with a brownish rough rind, which cracks irregularly, so as to form little scales. The root fibres emerge from the whole of the upper surface of the tuber, but principally from the rim; few or none issue from the lower surface. The leaves and flowers generally spring direct from the tuber without the intervention of any stem (a small stem, however, is sometimes produced, especially if the tuber be planted deep); at first they spread horizontally, but ultimately become erect. The leaves are variously marked, and the greater portion of them appear after the flowers, continuing in great beauty the whole winter and early spring, when they are one of the greatest ornaments of our borders and rockeries, if well grown. I have had leaves as much as 6 inches

long, 5½ inches in diameter, and 100 to 150 springing from one tuber. They are admirably adapted for table decoration during winter. The flowers begin to appear at the end of August, continuing until October. Mouth or base of the corolla ten-toothed, pentagonal, purplish red, frequently with a stripe of lighter colour, or white, down each segment of the corolla. There is a pure white variety, and also a white one with pink base or mouth of corolla, which reproduce themselves tolerably true from seeds. Strong tubers will produce from 200 to 300 flowers each. I have had as many as 150 from one plant blooming at the same time. The varieties from Corfu and other Greek isles are very distinct and valuable additions; there do not appear to be sufficient permanent characters for specific distinction. They generally flower later, and continue longer in bloom. Their leaves rise with or before the majority of the flowers, both being stronger and larger than in the ordinary type, with more decided difference of outline and markings on the upper surface of the leaves, the under surface being frequently of a beautiful purple. Texture thick, shining, and wax-like. Some of them are delightfully fragrant. They are quite hardy, but are worthy of a little protection, to preserve the late blooms, which often continue to spring up till the end of the year. This species is so perfectly hardy as to make it very desirable, not only for rockwork, but also for the open border. It will grow in almost any soil and situation, though best (and it well deserves it) in a well-drained rich border or rockery. It does not like frequent removal. It has been naturalised successfully on the mossy floor of a thin wood, in a very sandy, poor soil, and it may be naturalised with perfect success almost everywhere in these islands. It would be peculiarly attractive when seen in a semi-wild state in pleasure-grounds and by wood walks. It is very frequently sent out by English nurserymen and bulb dealers as *C. europæum*, though perfectly distinct from that species. It is well figured in Baxter's "British Flowering Plants," p. 505, and is the so-called British species; but it is doubtful whether it is a true native plant. *C. græcum* is a very near ally, if more than a variety, of *C. hederæfolium*; it requires the same treatment. The foliage is more after the *C. persicum*, or the southern var. of *C. europæum* type than most of the *hederæfolium* section; the shape of the corolla and the toothing of the mouth are the same. *C. africanum* (*algeriense macrophyllum*), much larger in all its parts than *C. hederæfolium*, otherwise very nearly allied; is hardy in warm sheltered situations.

**Spring *Cyclamen* (*C. verum*).**—Tuber round, depressed, somewhat rough or russet on the outer surface; fibres issue from one point on the under side only; under cultivation it has little or no stem, but leaves and flowers proceed direct from the upper centre of the tuber, bending under the surface of the soil horizontally before rising to the surface. Corolla long, segments somewhat twisted, mouth round, not toothed; colour from a delicate peach to deep red-purple, very seldom white; deliciously fragrant. Flowers from April to the end of May. Native of South Italy, the Mediterranean, and Greek isles, and about Capouladoux, near Montpellier. Leaves rise before the flowers in spring; they are generally marked more or less with white on the upper surface, and often of a purplish cast beneath; fleshy; semi-transparent whilst young. For many years I believed this species to vary in the outline and colouring of the foliage less than any other, but I have now received imported tubers from Greece, with much variety in both particulars, some of the leaves quite plain and dark green, others dashed all over with spots of white, others with an irregular circle of white varying much in outline. Among these very intermediate form occurs, up to that figured and described by Sibthorp and Sweet. The latter variety is the one more generally met with, and is reproduced from seed very true and unvarying. This, though one of the most interesting species, and perfectly hardy, is seldom met with cultivated successfully in the open border or rockery; it is very impatient of wet standing about the tubers, and likes a light soil, in a nook rather shady and well sheltered from winds, its tender fleshy leaves being soon injured. The tubers should also be planted deep, say not less than two inches to two inches and a half beneath the surface. I have grown them for many years in a border and on rocks without any other protection than a few Larch-Fir boughs lightly placed over them, to break the force of the wind and afford a slight shelter from the scorching sun. Some authorities give *C. repandum* as a distinct species, but I consider them identical, the only difference being in the shape and markings of the leaves, which are very variable. It is generally cultivated in England under the name of *C. repandum*, but most of the best continental botanists adopt the name of *verum* for it, and it is, no doubt, the original *C. verum* of L'Obel.

From the earliest times there appears to have been great difficulty felt by our best botanists in clearly defining the different species of *Cyclamen*, from the great variation in the shape and colouring of the leaves both above and below. Too much dependence

on these characters has been the cause of much confusion and an undue multiplication of species. Some of the varieties of this genus become so fixed, and reproduce themselves so truly from seed, as to be regarded as species by some cultivators. The following are some of the more important synonyms:—*æstivum* (europæum); *anemonoides* or *radice-anemone* (europæum); *autumnale* (*hederacifolium*); *Clusii* (europæum); *hyemale* (coam); *littorale* (europæum); *neapolitanum* (*hederacifolium*); *odoratum* (europæum); *Peakeannum* (europæum); *Poli* (*hederacifolium*); *repandum* (vernum); *vernum* of Sweet (coam, var. *zonale*); *zonale* (vernum of Sweet). *C. anemonoides*, *Clusii*, and *littorale*, are southern varieties of *C. europæum*, quite distinct from the northern type.

POLYANTHUSES AT BEDFONT.

THESE are still in beautiful condition, several large beds being full of plants that are producing magnificent trusses of fine flowers. Mr. Dean grows all the commoner kinds of *Polyanthus* from seed sown in April in the open border, the plants being afterwards pricked out or transplanted permanently. He, however, prefers sowing the seed in boxes of light soil, in pits or frames, in the same month, and when they have made a pair of rough leaves, pricking them out into other

as those that were left undisturbed. It is, therefore, evident that after the seedlings are once finally transplanted they should not be moved unless they get overgrown, when they should be lifted, divided, and replanted, unless fresh seedlings have been raised to take their place. *Border Polyanthuses* are, however, not the only ones grown in the Bedfont seed grounds; gold-laced ones may also be found here in excellent condition. These are what are known as true florists' flowers, and, therefore, special care is bestowed on them. They are, however, sown and treated precisely as the border varieties, but the finer kinds are always perpetuated by means of division after they have done flowering and have yielded seed. Among these exists every shade of colour, from velvety black to light red, whilst the form of the flowers and lacings is all that can be desired, the latter being of the same colour as that of the centre, the eyes being all thrums. Any plants deficient in these qualities are marked, and no seeds are ever saved from them. The trusses of these choice kinds are large and handsome, indeed their vigour is little short of that of their more commonplace companions.

*Polyanthus*, both of the common and fine kinds, will grow in any good garden soil, but a good loam, enriched with leaf-mould, and a partially-shaded situation, suit them best. At Bedfont, however, they are exposed to full sunshine, the soil there being the tenacious

Scene at the head of Lake in the Bois de Boulogne (after Alphand). (See page 355)

boxes, or most commonly into open borders, water being given until they have started into growth. The result of this treatment has produced in the succeeding spring excellent flowering plants, some bearing a dozen fine trusses, several of which contain from three to five dozen well developed blooms. If the plants are left undisturbed for another year their flowers will be infinitely more numerous than those just named, and the trusses will be larger and finer, a fact confirmed by several beds of two-year-old plants, arranged alongside of those containing one-year-old plants. Indeed, some of the plants that are flowering a second season have over two dozen trusses of bloom on them, and some of these trusses consist of over six dozen blooms; on one of these trusses, indeed, a fastigiated or monstrous one, we counted no fewer than 117 blooms. Nor is the size or quantity of flowers their only commendation; their strength of stalk and variety of colouring are also remarkable. Some of the flowers are almost black, others brown, red, pink, lilac, white, and yellow. Some are what are termed hose in nose, but these as a rule have weaker stems and more drooping flowers than the ordinary ones. One peculiar characteristic observable in these seedling beds is a tendency in almost all the plants to produce what are called thrum eyes. Another is that last season's one-year-old plants that were transplanted after they had done blooming are neither so strong nor so well furnished with flowers

London clay. Thus circumstanced, they, however, sometimes suffer from drought and sharp winds.

FRTILLARIA MELEAGRIS.

IN THE GARDEN, a week or two ago, appeared a short notice of that rare wilding, the Pasque Flower, or purple Anemone. That there are many field flowers suitable for cultivation in our gardens, few will, I think, deny; and, as the spring season is the time when our gardens lack beauty, or rather a variety of beauty, and the meadows and hedgerows are ablaze with it, permit me to call attention to two very handsome subjects which would make a marked addition to our spring flower garden. The first is the *Fritillaria Meleagris*, or common Fritillary, called by the country people "wild Tulip." This plant, which I found in abundance a week ago in a meadow about two miles from Reading, is comparatively rare, and, suitably disposed in our gardens, would form a graceful accession to their limited number of spring-flowering plants. Even in the wild state there are many varieties—the handsomest, perhaps, being the chequered white and reddish purple; there is also a white, or rather greenish white, variety, which is very pretty. The form of the flowers of all the varieties is very much that of a Chinese lantern. The foliage being scanty

and Grass-like, the bulbs, to produce an effect, should be massed in close proximity to handsome foliaged plants. The second wild flower to which I would call attention is that of the *Caltha*, or Marsh Marigold. The meadows near the river have been golden with the yellow blooms of this plant for the past three weeks. Either in masses or isolated, it is an exceedingly showy flower, and has no real defect to prevent its being an eligible occupant of the spring flower border. Its dark green glossy leaves are very handsome, and the plant grows compact and well furnished with blossom in the full sun. Indeed, so splendid was its appearance in the meadows, that I should only have been too pleased to have been able to transfer, there and then, some of its gorgeous beauty to my flower garden; but I was compelled to be satisfied with a handful of blooms, which I gathered, together with some *Fritillarias* from a neighbouring field, the two forming, on my arrival home, a vase bouquet sufficiently handsome for the *boudoir* of an empress.

T. S. JERROLD.

**Arundo Donax.**—The answer to "East Anglian's" question (see p. 316) is that it is entirely a matter of taste whether the *Arundo Donax* is more handsome grown as he proposes or cut down each year. But it may interest him to know that he can only get it to flower by not cutting it down. I never saw the flower, though I have often left the stems for two years; but the following note from the "*Hortus Collinsonianus*" shows that it will flower in England:—"Arundo Donax in flower September 15th, 1762; the first time I ever saw it, but this very long hot dry summer has made many exotics flower. Mr. Miller is greatly mistaken to say that it dies down every year; in my garden the stalks have continued some years to make annually young green shoots from every joint. It bears a handsome tassel of flowers.—P. Collinson."—H. N. ELLACOMBE.

— Allow me to inform "East Anglian" (see p. 316) that it is of no use to allow the old stems of his *Arundo Donax* to remain; the laterals will come to nothing in the way of ornament, and the old stems will greatly impair the beauty and effect of the new ones. As to layering them he can do so, and the side shoots will in some instances root; but he can as easily take them off and strike them in a frame or under a bell-glass out-of-doors. This *Arundo*, however, grows so rapidly and throws out so many stems from the old roots, that it is hardly worth while to use any other method of propagation than that of division. I have several times tried to throw this magnificent Grass into flower by tying up the stems in straw during the winter, anticipating that they would flower the second year, but with no effect. I have never heard of its flowering in this country. In Madeira, I am told it is magnificent. It should have a barrowful of sifted ashes put over its roots in winter, as it is sometimes killed by severe frosts. Your correspondent should get the variegated sort; it is one of the finest of outdoor ornamental foliaged plants.—J. SCOTT, *Merriott Nurseries, Crewkerne*.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Solanum capsicastrum.**—This popular plant forms a showy bush in a sheltered nook in front of a range of glass at Preston Hall, the berries being quite showy. In severe seasons, however, it gets killed down.—M.

**Veronica Devonensis.**—This handsome *Veronica* deserves to be much better known; it is so neat in foliage and so glossy in hue as to be quite pleasing during the winter and spring months, while it flowers abundantly on favourable soils, as at Wimbledon.—F.

**Yucca Stems as Supports.**—Among the best stakes we have ever seen are the dead flower-stems of *Yuccas*, nicely branched, and of a convenient height. They are the handiest things one can use for climbing annuals and dwarf or delicate climbers of any kind. Mr. Ellacombe finds that they last three years.

**Gentiana acaulis.**—Looking at some old beds of this at Preston Hall the other day, lovely with glorious blue, we could not help wondering how it is that such a precious plant is so seldom seen, and where seen so often allowed to struggle half-shaded or half-killed by shrubs and coarser plants. At Preston Hall the small beds of it are fully exposed, and have not been disturbed for years, the result being perfect health and abundant flowers. Plenty of water is given in summer.—R.

**Iris pumila, var. lutea.**—This was formerly in cultivation, and has been figured in the *Bot. Magazine*, vol. 39, plate 1,299. A few days ago I found it in abundance on the south side of the Paris and Marseilles Railway, three miles west of Entressant station, near Marseilles, where it varies in colour from rich orange to delicate citron, and is associated with the ordinary blue and other coloured varieties. Nothing can exceed the beauty of the large tufts, covered with canary-coloured flowers.—G. Maw, *Bentall Hall*.

**Spring Flowers for Next Year.**—When should seeds for next year's spring flowers be sown? And will you give a list of a dozen of the best? They would be sown in good ground and transplanted in September.—S. W. [All the perennial spring flowers, such as *Polyanthuses*, *Primroses*, *Arabis*, *Aubrietia*, *Alyssum*, *Iberis*, *Viola*, &c., should be sown as soon as possible, and we should prefer sowing them in beds in the open air. The biennial kinds of spring flowers, such as *Silene pendula*, *Myosotis sylvatica*, *Centaurea Cyanus*, &c., should be sown about the end of July. The quicker growing annuals, such as *Virginian Stock*, the *Nemophilas*, &c., may be sown in September. We shall publish lists of the best spring flowers next week.]

## THE KITCHEN GARDEN.

### ASPARAGUS.

(Continued from p. 312.)

#### CUTTING.

**ASPARAGUS** should not be cut till the second year after planting, and then only sparingly. By allowing the plants to get well and firmly established before making a very free use of the knife, and with judicious after-treatment, they will produce excellent crops for many years; and at no time cut too severely, but bear in mind that the more copious and healthy the foliage during the summer, the stronger will be the produce next spring. As the strength of the roots depends on the quantity of foliage, there must be shoots enough left to sustain them healthy and vigorous, and to replace and store up for the following season sufficient matter for the healthy action of the plants. It is not advisable, however, to cut away the strong shoots and leave the smaller ones; quite the reverse. Allow some of the finest shoots to grow after the first fortnight or three weeks' cutting is over, removing any small spray that may appear; for a few strong shoots to each plant, properly exposed to light and air, will be more beneficial than any quantity of small ones. In cutting, a little of the soil is removed from the necks of the shoots with the Asparagus knife, which is then pushed down, carefully avoiding injuring the crown or other shoots that may be pushing up. When the knife is at the base of the shoot, give it a slight twist towards, at the same time pressing it close to, the shoot; then draw it gently upwards, by which process the shoot is separated from the plant. The knife generally used in this operation has a rough or saw-like edge, set to cut only one way, and that by pushing down. It should always be kept sharp at the three or four first teeth from the point. For those that are fond of natural unbleached "grass," any kind of knife will do, and in kindly growing weather the heads may even be broken off without a knife. Asparagus for market is generally blanched by the earthing-up system, which is done by covering the crowns with a few inches of light soil, generally taken from the space between the rows, by which process we obtain the white bleached or blanched shoots daily seen during the season in the London market. When this method is adopted, the shoots must be cut below the surface just as it appears above ground. This mode, however, is not to be commended, the right way being, not to practise the earthing-up system, but to wait till the shoots are 6 inches above ground, when they may be cut over almost level with the surface. By so doing we obtain the Asparagus in its green and natural condition and of exquisite flavour, to which the blanched can bear no sort of comparison. The cutting season should cease about the middle of June, and in no case should it be continued after the end of that month. When green Peas can be had, Asparagus is less required; therefore it is desirable to discontinue cutting after the 10th or 15th of June.

"The waste of good food sacrificed at the fashionable shrine of blanched, stumpy crowned Asparagus is fearful to think of. Here is all the strength of the root run up into a white, leathery skin, with a sweet crown at the end thereof, while we might have 6 or 8 inches of sweeter, better-flavoured eatable "grass" to nibble at and eat quite up. Custom not only makes slaves of us all in various ways, but in the matter of Asparagus it robs us of more than four-sixths of the choicest food. And yet year after year we go on tasting crowns, while we might feed on good-sized stalks. And the latter are positively the best in quality. As long as an Asparagus stem will break off sharp, without leaving tough skin or fibry threadlets behind, it is excellent and sweet for food. Indeed, for soups it is generally used in a green state. The flavour is superb, and it leaves no leathery wreck behind. I wonder what sort of soup the white underground stem would make? or how many crowns it would take to make good soup? The whole system of gathering Asparagus is wrong. First of all, by grubbing underground after the incipient stems, we often cut or wound more than we gather. Even the fleshy roots frequently suffer severe laceration, and then the base that we are so anxious to get is of no use. Connoisseurs, indeed, will tell us that the bottom serves the purpose of a handle. A handle! ah, yes; we hold on by the bottom while we nibble off the sweet crown.

Why not also have a handle to your Cauliflower and Broccoli? A tough Kale stalk would afford a good hold while the crown was divided and discussed with white sauce. But, seriously, would it not be better to cut and serve only edible Asparagus? Nothing can be easier. Simply let it grow 4 inches or 6 inches high, and then cut it off close to the ground; every morsel of it would then be tender and sweet. Of late years I have been gradually getting quietly into this system of culture, sliding into it, as it were, a half an inch at a time, so as not to alarm the kitchen authorities, who are the most inveterate sticklers under heaven for the rights, real or imaginary, of those two great obstacles to improvement—"use and wont." Once safely through the kitchen, the green Asparagus is safe; it is so much appreciated in the higher regions that little of it returns, and one hears cheering reports of its full-bodied flavour and unusual sweetness and crispness along its entire length."

To the above remarks, for which I am indebted to Mr. Fish, it may be well to add that those who eat and know most about Asparagus greatly prefer it in the partially blanched condition.

FORCING ASPARAGUS.

There are several ways of forcing Asparagus, all depending on the same principles, yet each adapted to a different kind of garden. Some are expensive, others not at all so, where stable manure is plentiful and garden labour not a scarce commodity. In my days in the London market gardens a large forcing grower would purchase an acre or more from the grower, and send for it as his beds were made. I have frequently sent several waggon-loads of roots away in one day to forcing gardens on the opposite side of London, where they used to supply it in good condition from Lord Mayor's-day till it came up naturally in the open garden the following spring. At that time heating hothouses or pits of any kind by means of hot water was of course unknown. They employed a great number of common garden frames. A trench a foot or so wider than the frame and 15 inches deep was then cast out, and in this was placed about 2 feet of London stable manure, and on this again a few inches of the rich friable earth of the old market garden which had been cast out of the trench, to secure the heat from evaporating. Then soon after the frames were placed in a straight line on the hotbed, the plants were very carefully placed on the soil in the frame, covering them immediately with 3 or 4 inches more soil, or more if the Asparagus was required blanched throughout. If wanted quite blanched, of course air and light were not admitted. Every twenty-four days or so a fresh set of beds was made to keep up the supply.

Forcing may be commenced in November and continued till Asparagus is fit to gather in the open air. One of the best ways is to make a slight hotbed with stable manure, leaves, tan, &c. (these last materials, if easily obtained, will do well to mix with the manure), in a Melon pit, or under a common Cucumber frame. Two and a half feet high will be quite sufficient, and on the surface of the bed should be placed a few inches of light soil, leaf-mould, or sifted potting refuse, on which to place the plants, because such material does not act so decisively in repressing the heat as ordinary garden soil; and when the roots are taken up as completely and carefully as possible and placed thickly on this, they should be covered with a few more inches of the same material. If the Asparagus be required of its natural colour—and that is unquestionably the best way to enjoy it—give the frame full light and air when fine. Water occasionally with tepid water. After one good watering in the early stage, little will afterwards suffice for the winter crops, at all events, as the slow evaporation of the period and the natural moisture of the bed will preserve the soil in a nice moist state. The heat of the bed must be preserved when it gets low by a lining, in the usual old-fashioned way, by covering closely with mats or litter at night in cold weather—that is, if it be a common frame, but if in a brick pit this will not be necessary. The chief point is to be patient at first, to let it get a slow start, and not be over excited at any time, or it will start away and produce nothing but very weakly, spindling shoots; whereas, by bringing it on gradually and regularly, a really respectable cutting may be obtained.

It is also frequently forced by being placed on the floor, or on a bench or pit of some kind, in an early vinery or other forcing house; and, whenever there is space to spare, and the

heat brisk and genial enough, this is a good plan. Another very important way is by bringing the heat to the roots, and certainly by this plan a more permanent and stable kind of "grass" is obtained, because plant or root is not in the least disturbed. But it is an expensive way, though simple. The beds are in the first place very well made of rich soil, deep, too, and the alleys of these beds are dug out to a depth of 3 feet or so, and then bricked; or, in other words, the Asparagus beds are made between low brick walls, perforated with "pigeon holes," to admit of the heat entering freely; and whenever forcing commences, the bricked trench on each side of a bed is filled with fermenting manure, covered over by a rough shutter, and the beds themselves with small wooden frames made to fit; these are, of course, only placed on during forcing, the beds being exposed in the summer season. The beds should not be more than 4 or 5 feet wide, to admit of the ready percolation of heat. This method is, however, only suited for places where a good deal of expense is devoted to the garden; and the modification or improvement of it, which consists in having hot-water pipes pass between each bed and the chamber covered with a slab of stone, is a much more expensive one. No matter what system be employed, a steady heat of from 60° to 65° will be found most suitable.

Another way of heating the beds is by means of hot-water pipes. This is a modification or improvement of the last, and is the same as is practised in the Royal Gardens at Frogmore. This is certainly a very expensive method; yet it must be admitted it is the most satisfactory in the end. At Frogmore the beds are 75 feet long and 7 feet wide, their sides being built with brick, "pigeon-hole" style. The spaces between the beds are 4 feet deep, the lower 2 feet being filled with rich soil; and in the upper 2 feet are a flow and return hot-water pipe connected with a boiler that heats six such ranges. On the top of the beds are special frames. In severe weather, the sashes must be covered with mats or litter.

Mr. Gilbert's mode of forcing Asparagus is clearly illustrated by the annexed diagram, and it is that adopted to a great extent in the market gardens. The beds are 5 feet wide, with 3-foot alleys between them. The alleys are dug out to

Section of two Beds with Alley between them, and half of two corresponding Alleys.

the depth of 2 feet, the soil being spread over the surface of the beds, on which frames, covered with sashes, boards, or shutters, are placed. The space between the beds, being 4 1/2 feet deep and 3 feet wide, is filled with fermenting material, such as stable dung and leaves, as are also the outside half alleys. Before filling these spaces with litter, we make holes into the sides of the beds large enough to admit a one-inch bore drain-pipe. These holes we find beneficial in admitting heat to the interior of the bed. The side trenches are filled with hot dung to the height of the frames, the beds in which, marked A A, are also covered with the same materials until the heads make their appearance, when it is removed. If white Asparagus is wanted, the frames are kept dark by being covered with shutters; but, if green is preferred, glazed lights should be put on. After the fermenting material is removed from the beds, the frames are kept close for a few days, after which a little air is given on favourable occasions, a practice which increases both flavour and quality. It is necessary to maintain a temperature of 60° or 65°, but at no time should it exceed 70°. When this heat cannot be kept up, fresh linings must be added.

(To be continued.)

JAS. BARNES.

The Canada Victor Tomato.—Mr. J. H. Gregory, of Marblehead, Mass., a trustworthy observer and large grower of Tomatoes, reports that this is the earliest Tomato he has ever tried by from six to eight days. Its other qualities are also of a high order. We are not aware that it is yet to be had in England.

## GARDEN STRUCTURES.

## RAIDISSEURS SUPERSEDED.

A GREAT many contrivances for tightening wires have been offered to the horticultural public. They are all more or less ingenious, and answer the purpose required; but they are all more or less expensive, and economy of time and money is the great desideratum in horticulture more than in any other pursuit. M. Jean Sisley, of Lyons, sends us the following: "A gardener of our city—M. Ravet—has invented the following most simple, most economical, and most effective mode of tightening wires. On the wire to be tightened he makes a loop A (as in the figure), through which he passes a piece of wire (B), which he turns round the pole C, to which the wire is to be fixed, and with a pincers he twists the two

ends (D) till the wire is tightened. This invention supersedes all the much extolled contrivances called French raidisseurs, &c."

## LIME KILN HEATING.

WITH reference to Mr. Cowan's plan of heating by means of lime burning, of which we gave an illustration and description last week (see p. 317) from notes made on the spot by Mr. Noel Humphreys, we gladly republish from the *Gardeners' Record* the following confirmatory testimony as to its merits by Mr. Roberts, of Charleville, who is one of our very best Grape growers, and altogether a skilful gardener and painstaking observer:—

I have had (he says) an opportunity of inspecting this system. The first object of attention was a lime kiln, I will say No. 1, with boiler attached. This is the first one which Mr. Cowan erected. It heats several detached houses, with both bottom and top heat, and there cannot be a doubt about its efficiency. The pipes were regularly heated, and hot all through, and this for twenty-four hours, without any attention to the kiln. The next kiln which I examined I will call No. 2. It is larger than No. 1, and, with its boiler, heats a grand range of houses 200 feet long in several divisions, in which over 1,000 feet of piping are in constant use. I saw the work of drawing the lime burned in the twenty-four hours, the quantity taken out, and the quantity of small coal or slack, and the necessary quantity of broken limestone used to complete the charge for another twenty-four hours. This "charge," shall I call it such? was made at about eleven o'clock a.m., and at six p.m. I examined it, and found on opening the furnace door a grand heat, which very much put me in mind of the glow of fire one sees in a railway locomotive engine when the doors are first opened. All the pipes were regularly heated, and as hot as scarcely to be bearable to the hand. At eleven o'clock on the night of the day of charging I again examined the kiln, and all was burning up to the desired height in the kiln, and that, be it remembered, since eleven o'clock a.m. I then proceeded to try the piping, and found all satisfactory—the houses being heated up to just 27° above the outside temperature. This was very satisfactory, and I retired to rest. Next morning, after breakfast, I again made another inspection, this being the fourth since (I was going to say) "making up time"—charging at eleven o'clock a.m. the previous day. The glow in the kilns was just as bright as it was over-night, and the heat just as steady in the houses. I left Mr. Cowan perfectly satisfied with his new system, and congratulated him on his happy hit, wondering much how stupid I was that I could not have invented such a simple contrivance myself.

Some, I have no doubt, will say, "What about the cost of the apparatus, &c.?" Well, to be candid, I did not go into those matters with Mr. Cowan; though I am sure, if I had wished, he would have given me every particular in that respect.

I saw the lime taken out (this is done every twenty-four hours—bear this fact in mind; your stoking can be done during the day; and, once charged, it is continued by renewing every twenty-four hours), and it was of the best description—good, nice-sized lumps.

I saw the slack or small coals used, and I was assured and convinced by Mr. Cowan that the value of the lime made more than compensated for the cost of fuel and labour in procuring stones, breaking, &c. Where limestone exists in abundance, as it does here, the heating of hothouses will be a paying instead of a losing game to the owners. I, for one, have to thank Mr. Cowan for his inventive powers. His system will, I am sure, answer admirably at Charleville, for here we have plenty of limestone, and we certainly are always wanting lime. I shall strongly recommend the principle to my noble employer, and I expect in a year or two hence I shall be told to "fire away, we want more lime." Won't that be a much more pleasant sound than "reduce your forcing; the cost of coals is something enormous?"

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**Flower Garden.**—Spring flowers, such as Pansies, bedding Violas, Daisies, Aubrietias, Forget-me-Nots, Alyssums, single and double yellow and crimson Wallflowers, Trillium grandiflorum, Trolliuses, Saxifrages, Tulips, &c., are now in perfection, whilst fine-foliaged plants are beginning to be extremely pretty. Preparation must now be made for summer bedding plants; all beds, therefore, not occupied by spring-flowering plants should be lightly dug, levelled, and otherwise made ready for planting; a dressing of leaf-mould is sometimes of much service, especially for Pelargoniums, and in the case of Alternantheras and other plants with highly-colored leaves, peat has been found efficacious in bringing out the variegation. Edgings of *Echeveria secunda glauca* and others, together with *Sempervivums* of various sorts, should be made at once, for, if properly hardened off previously, they will stand a slight frost with little harm. *Funkias* have now begun to grow, and, if necessary, may be lifted, divided, and replanted. Remove from beds of *Cannas*, in which the roots were wintered in the open ground, the mulching of leaves, litter, or Grass with which they were covered, as the plants have begun to grow, and the beds should be top-dressed with some well-decayed manure and loam. *Spiraea filipendula* makes a fine summer edging for beds, and it may now be transplanted, as may also variegated Grasses, for the same purpose. *Polemonium eceruleum variegatum*, variegated *Arabis* of different sorts, autumn-sown plants of the golden-leaved *Feverfew*, Japanese *Honeysuckle*, and bedding Pansies and Violas. Carnations wintered in pots should now be planted out and staked; also *Hollyhocks* propagated this spring. The commoner *Yuccas* wintered in frames may now be assigned to the open borders, as may also *Pentstemons*, *Phloxes*, *Antirrhinums*, and *Irises*. From the base of clumps of *Pampas Grass* cut away the most decayed leaves, and administer a thorough soaking of water to the roots. *Campanula carpatia* may be divided and replanted; this makes a grand edging for a shrubby border, as does also the *Nepeta violacea*, the herbaceous stalks of which should be removed so as to give freedom to the young growth. Lift, divide, and transplant *Neapolitan* and other early blooming *Violets* in a somewhat shady border; place some sandy soil around the roots of each plant, and water them freely when necessary; good year-old plants always make the best flowering ones. Sow *Polyanthuses* and *Alpine Auriculas* at once on a warm border, and divide and transplant the old ones as soon as they have done flowering in a somewhat shaded border; they thrive well in a good loamy soil mixed with leaf-mould; it is, however, unnecessary to disturb the old stools unless they have become overgrown. *Wallflowers* may still be sown, but the earlier now the better. Pansy seed may also be sown, cuttings propagated, established plants transplanted, and the seedlings from sowings made early in April in boxes or frames pricked out or planted permanently. Suckers should be removed from *Roses*, and any buds that appear on the stems of standards should be rubbed off from last year's budded *Roses* too; remove all shoots and eyes except one beyond the bud, which should be left to draw up the sap until the inserted bud has strength enough to perform that office for itself, when the other shoot should be gradually reduced and eventually removed. Look after *Rose grubs* and other pests, to which the Queen of flowers is liable.

**Shrubberies.**—Young bright-green leaves and opening blossoms render these always attractive at this season of the year. *Amelanchier* and *Cherry* flowers are now almost past; but *Berberries* of different kinds are now in good condition, as are also *Apples*, *Pears*, flowering *Currants*, *Magnolias*, *Laurustinus* and Japanese *Quinces*. The dwarf *Almond*, too, is now in full beauty, and forms a fitting associate for small plants of *Prunus triloba* and *sinensis*, and the *Rosemary*. These will soon be followed by *Hawthorns*, *Chestnuts*, *Cotoneasters*, *Spiraeas*, tree *Paeonies*, and several other shrubs, as well as by masses of *Rhododendrons*, &c. *Shrubbery borders*, if not previously done, should now be lightly dug or hoed. Unnecessary

suckers should be removed; for, in the case of flowering plants, not only do suckers look untidy and rob the trees, but the shrubs, encumbered in that way, never flower so freely nor produce such good flowers as they would do without them. Maintain neatness in every way by a frequent use of the broom, hoe, rake, and mower. Have walks in good trim, and apply fresh gravel if necessary; use the roller frequently on them in damp weather.

**Bedding Plants.**—The coldness of the weather has considerably retarded the progress of bedding plants, and has called for more than usual attention to keep them in good condition; consequently they are not so well hardened off as they usually are, thus rendering the bedding-out season this year a little later than it commonly is. Pelargoniums of all sorts, for planting out, should be gradually inured to the weather, and the hardier kinds all but fully exposed. Unless between hedges, under canvas, or beneath the canopy of some densely topped trees, it would be dangerous yet, however, to risk them out of frames or pits. Old stumps of Fuchsias may safely be planted out and staked, but those started into growth indoors must be kept there until the weather becomes warmer. *Centaurea ragusina*, if required for specimens to be set in a carpet-work of Lobelias or other plants, had better be plunged in the pots; they may now be placed in open frames. *Cineraria maritima*, pricked out in frames or potted, should have the sashes tilted up in front and at back. *Centaureas* now strike freely from cuttings, therefore a stock of them should be secured. Boxes, pans, or pots containing *Gazania splendens*, may be arranged out-of-doors along the base of a wall or hedge in a well-sheltered position. Pot off the youngest lot of *Verbenas*, *Ageratum*s, *Tropæolum*s, *Lobelias*, &c.; keep them in heat for a week or so until they begin to grow again, and then remove them to a cool house or close frame, and gradually harden them off. Propagating Dahlias for ordinary use should now be at an end. Established cuttings and divided roots making growth should be removed to a cold frame, which should be kept close for a time, but eventually thrown open. Keep *Perilla* in a cool frame, and plant out Dell's Crimson Beet where it is to remain. *Alternantheras*, *Iresines*, *Coleuses*, and *Amarantuses*, keep rather warm yet, and encourage good stocky growth. To these *Fuchsia Meteor* makes a fine companion, and from early spring-struck cuttings nice plants of it should be had for bedding-out. Sweet Peas, *Tropæolum canariense*, and climbing *Nasturtiums*, may now be planted out from the pots or boxes in which they were sown; they are sometimes raised in narrow wall borders, and afterwards transplanted. Stocks, Asters, Balsams, *Tagetes*, African and French Marigolds, *Brachycome iberidifolia*, and similar plants, if in boxes, should be kept in frames, and the sashes should be tilted up both at back and in front; the Marigolds may be pricked out and kept in a warm position for another week or so if necessary. Supply sub-tropical plants freely with water at the root, and syringe them twice a day; a sprinkling of tobacco water from the syringe now and then helps to keep them free from greenfly and thrips, and is essentially useful in the case of soft-wooded plants. Gradually reduce the artificial heat where sub-tropical plants are kept.

**Indoor Fruit Department.**—For Pines maintain a steady night temperature of from 70° to 75°, allowing a rise of 10° throughout the day. Transfer such plants as are beginning to ripen to a cool part of the pit and keep them moderately dry at the roots. Slightly syringe all pot plants at shutting up time, also such as are planted out; a sprinkling from the waterpot, however, is generally sufficient for them. The early Fig crop on plants or borders has been rather unsatisfactory, but the second one promises to be good. Keep shoots of Figs well spread out, and pinch all young shoots at the fourth joint. Plenty of water should be given; weak manure water should be occasionally applied, and the plants should also be well syringed. In early Vineries, in which Grapes are ripe, the temperature should be moderately low and the atmosphere comparatively dry. Continue to tie in young shoots and stop laterals in the succession houses. Admit plenty of air to Cherry houses, and keep up a moderately moist atmosphere by sprinkling the paths and floor; as the fruit approaches maturity, gradually lessen the amount of atmospheric moisture and the supply of water at the root. Tie in shoots of Peaches and Nectarines in the latter houses, but avoid overcrowding, and freely syringe the trees. Remove any leaves that shade the fruits, in order to increase its colour and flavour. Fumigate if greenfly is troublesome, and mix some flowers of sulphur with the water for syringing in order to keep down red spider. Keep the syringe well at work amongst Melons and Cucumbers, and do not permit too much lateral growth to be on the plants; better have a moderate quantity of good foliage than a mass of indifferent leaves. Introduce successions of Strawberries from pits. Maintain a good supply of French Beans in heat, and harden off Tomatoes in cold frames for planting out. Plant out Vegetable Marrows under handlights in warm positions, and on manure heaps.

## SOCIETIES, EXHIBITIONS, &c.

### ROYAL HORTICULTURAL SOCIETY.

(MAY 7.)

THIS, though not one of the Society's large shows, was nevertheless one of great interest. Roses, Azaleas, and Orchids formed the principal part of the exhibits, yet many things of a miscellaneous character were also shown.

**Roses.**—These were exhibited in wonderfully fine condition by Mr. C. Turner—perfect models as regards cultivation. They were shown six in one class and twelve in another; they were fully 6 feet in diameter, each specimen being laden with some five or six scores of fully expanded flowers, besides a multitude of buds. To these were deservedly awarded first prizes in the classes in which they were shown. They consisted of *Maréchal Vaillant*, *La France*, *Miss Ingram*, *Victor Verdier*, *Madlle. T. Lovet*, *John Hopper*, *Souvenir de la Malmaison*, *Souvenir d'Un Ami*, *Charles Lawson* (fine), *General Jacqueminot*, *Alfred Colomb*, *Mad. de St. Joseph*, *Paul Verdier*, *Celine Forestier* (fine), *Beauty of Waltham*, and *Anna Alexief*. A dozen fine specimens of Roses were contributed by Messrs. Paul & Son; conspicuous among them were *Juno* (fine), *Marie Baumann*, *Mad. Victor Verdier* (splendid colour), *Horace Vernet*, and *Elie Morel*. Messrs. Paul & Son exhibited moreover a superb collection of cut blooms, which were awarded a first prize. In the amateur's class, Mr. E. Ellis, Coombe Warren, Kingston Hill, was first, and Mr. James, Isleworth, second; the plants in both these collections were large and fine. In the class of twenty new Roses of 1870, '71, and '72, in 8-inch pots, Messrs. Paul & Son were first, Mr. Turner second, and Messrs. Veitch & Sons third. Those in the first prize group, all of which were well grown and flowered, consisted of the following, viz., *André Duand*, *Richard Wallace*, *Mad. George Schwartz*, *President Thiers*, *Lyonnais*, *Etienne Levet*, *climbing Victor Verdier*, *Coquette des Blancches* (a pretty pure white), *Annie Laxton*, *Baronne Louise Uskull*, *Baronne de Prailly*, as *Hybrid Perpetuals*; and of tea-scented ones there were *Perfection de Montplaisir* (superb buds of a bright canary-yellow colour), and *Cheshunt Hybrid* (extremely fine).

**Azaleas.**—These consisted of large bushes and small plants, the finest blooms being on the latter. Mr. Turner was first for the best single specimen, with an immense white-flowered kind. Mr. Ward, of Leyton, was similarly placed in two classes for three distinct kinds, consisting of *Flower of the Day*, *Madame Miellez*, and *Sinensis*, in one case; and *Louise Margottin*, *Duc de Nassau*, and *Sinensis* in the other. Other exhibitors were Messrs. Dobson, Wheeler, Hill, Slogrove, Rowe, and Marcham. A group of Azaleas from Messrs F. and A. Smith, of Dulwich, contained some good kinds, particularly a fine white sort, called *Beauty of Surrey*.

**Orchids.**—Of these there were some fine groups, and also several novelties. Mr. Ward showed half-a-dozen grand specimens of *Lycaste Skinneri*, and a group containing a splendid specimen of *Phalenopsis grandiflora*, a large and well-flowered plant of *Oncidium ampliatum*, a specimen of *Dendrobium Farmeri*, with eleven flower-spikes on it, and a fine plant of *Cypripedium villosum*. Mr. Wheeler showed half-a-dozen plants of *Lycaste*, consisting of *Skinneri*, *cruenta*, and *Harrisoniæ*. From Mr. Denning, gardener to Lord Lodesborough, came some excellent Orchids, amongst which was a plant of *Aerides Veitchii*, with one flower-spike, on which were eleven well-developed branchlets; a finely-bloomed specimen of *Dendrobium infundibulum*, a good plant of *Cattleya Mendelii*, and one of *Mossiæ*, a finely-flowered specimen of *Cyrtopodium punctatum*, several *Vandas*, a fine mass of *Oncidium bifolium*, and superb plants of *Odontoglossum Phalenopsis*, and *Saccolabium guttatum*, *curvifolium*, and *ampullaceum*. Of *Odontoglossum Phalenopsis*, a most excellent specimen was exhibited by Mr. T. Hubbersty, Bridge Hall, Bury. It measured over 2 feet in diameter, and was laden with flowers; last year this plant was awarded the Lindley medal. From Messrs. Veitch & Sons came, however, the gem amongst Orchids, in the shape of *Odontoglossum vexillarium*, bearing two flower-spikes, each having four delicate violet peach-coloured flowers. The same firm also sent an extremely handsome new *Masdevallia*, *M. Harryana*, a fine plant of *Cypripedium Dominionum*, finely-flowered plants of *Camarotis purpurea*, *Dendrobium Devonianum*, *Saccolabium curvifolium*, &c., together with some fine-foliaged plants. Mr. Wm. Bull contributed excellent plants of *Arpophyllum giganteum*, *Cypripedium superbiens*, *Odontoglossum crispum*, several *Vandas*, *Lycastes*, and others. Messrs. Rollisson furnished a splendid plant of *Saccolabium ampullaceum monheimense*, a nice specimen of *Calanthe Rollissonii*, with two fine spikes of bluish flowers; a good specimen of *Oncidium sphacelatum*, some *Cattleyas*, *Phalenopsis*, and others.

**Miscellaneous Plants.**—From Mr. W. Bull came a large and varied collection of plants, amongst which were *Elaeocarpus reticu-*

latus, a fine white-flowered tender shrub; a grand plant of *Cochlostema Jacobiana*, with half a dozen flower-spikes on it; a nice plant of *Richardia maculata* in flower; a good specimen of *Amorphophallus campanulatus*, a large plant of the beautiful *Alocasia illustris*, and plants of the pretty variegated *Aralia Guilfoylei*, *Ravenala amazonica*, *Cyrtodeira fulgida*, *Anthurium Scherzerianum*, and others. Messrs. Veitch contributed a basketful of the splendid *Spirea palmata*, whose attractive red flowers and hardness of constitution must ever render it a great favourite. Mr. Noble again sent a fine collection of Clematises. Messrs. Rolliison furnished a large mixed group of plants, containing some good Palms, Conifers, Heaths, Eriostemons, &c., for which a first prize was awarded. Messrs. F. & A. Smith sent a group of hard-wooded greenhouse plants in flower, and Mr. J. Aldous a fine group of fine-foliaged plants, Palms, Conifers, Dracenas, &c., for which an extra prize was awarded. Mr. Wheeler sent a collection of stove and greenhouse plants; and Mr. J. Welch, Hollycomb Gardens, Liphook, Hants, a few examples of the extremely prettily-variegated *Habrothamnus Hawkshaurianus*. *Veronica Hulkeana* was contributed by Mr. Macintosh, nurseryman, Hammer-smith. *Dracena rubra*, a finely bloomed example of *Anthurium Scherzerianum*, called *Hendersonii*, some tree Carnations, and *Caladiums* were shown by Messrs. E. G. Henderson and Son. A fine boxful of cut flowers of stove and greenhouse plants, and a beautifully crisped form of *Athyrium Filix-femina virgatum* came from Mr. J. Chambers, Biddington; a group of seedling *Echeverias* was furnished by Mr. Webster, Gordon Castle; a seedling *Gloxinia* by Mr. Gordon, Wimbledon; and some seedling *Pelargoniums* by Messrs. Smith, of Dulwich. Messrs. Burr and Sugden sent some plants of the extremely pretty and quite hardy *Cotyledon spinosum*; W. B. Kellock, Esq., Stamford, furnished a plant of *Phyllanthus latifolius*; Mr. J. Douglas, Loxford Hall, sent an excellent rosy-lilac flowered seedling raised from *Statice armeria speciosa*; Dr. Denny furnished some very fine-flowered zonal *Pelargoniums*; and Mr. Goddard, Richmond, half a dozen fine specimens of *Mignonette*. A large group of well-coloured tricolor *Pelargoniums* was furnished by Mr. Pestridge, Greenway Nurseries, Uxbridge; and a large collection of succulents, composed of *Gasterias*, *Echeverias*, *Sempervivums*, *Opuntias*, *Aloes*, *Mammillarias*, and other plants were sent by Mr. Ware. From Chiswick came a great quantity of cut flowers of red *Camellias* that had been cut from plants grown in the open air.

**Florists' Flowers.**—Messrs. Dobson & Sons sent a fine collection of herbaceous *Calcicolarias*, for which they were awarded an extra prize, also a second prize for half a dozen plants. Mr. James being first, and Mr. G. Warren, Willesden, third. A group of fine specimens of *Cinerarias* was furnished by Mr. W. Lacy, Wigmore Park, Dorking, an extra prize being awarded for them, and another collection with large and well coloured flowers came from Messrs. J. Stanish and Co., who also sent a specimen of the white-flowered *Abutilon Boule de Nige*. A collection of gold laced *Polyanthes*, for which an extra prize was given, and a remarkable double, or rather Carnation-flowered *Polyanthes*, having the gold lacing well marked, were sent by Mr. J. Goddard, The Retreat, Richmond. Of Alpine *Auriculas* a splendid collection was furnished by Mr. Turner. For the best twelve Alpine, and also for the best twelve show *Auriculas*, Mr. Turner obtained first prizes. Mr. James, Messrs. Dobson, and others also showed in these classes. A very fine collection of cut flowers of fancy and English Pansies, and plants in pots was exhibited by Mr. Brage, of Slough; collections of the same were also furnished by Messrs. Dobson & Sons and Mr. Ware.

**Fruit and Vegetables.**—A collection of Apples was shown by Mr. W. Gardiner, Lower Ealington Park, Stratford-on-Avon. They were in a state of good preservation, and were awarded a cultural commendation. Conspicuous amongst them were *Hanwell Souring*, *Gloria Mundi*, *Broad-eyed Pippin*, *Grosse Reinette d'Angleterre*, *Northern Greening*, *Bess Pool*, *Corsehill*, *Forester*, *Nonpareil Scarlet*, *Yorkshire Greening*, *Alfriston*, *Round Winter Nonsuch*, *Greenup's Pippin*, *Rymer*, *Royal Russet*, *Adam's Pearmain*, *Lewis's Incomparable*, *Dutch Mignonne*, &c. Some excellent Dr. Hogg Strawberries were shown by Mr. Hopper, Hartwell House, Bucks; and Alice Maud, by Mr. W. Stevens, Chesterford Park, Essex. From Mr. Jones, Royal Gardens, Frogmore, came clusters of Black Hamburg and Buckland Sweetwater Grapes from pot Vines one year old; also specimens of the Hedsor Cucumber, which in the Royal Gardens is regarded as the best Cucumber for general purposes, especially for winter work. A cultural commendation was awarded to Mr. W. Coles, gardener to W. K. Wigram, Esq., The Chestnuts, St. Margaret's, Twickenham, for some good Pears. Messrs. Hurst & Son, Leadenhall Street, exhibited a brace of Telegraph Cucumbers, and also one of Munro's Improved Rabley, which is an excellent free bearing variety. Messrs. Waite, Burnell, Huggins, & Co. exhibited some fine heads of Taylor's Yorkshire Hero Broccoli, which were large, firm, and very fine; and Mr. A. Parsons, Danbury Park, Welwyn, showed some of

Saublers' protecting late winter Goshen Broccoli, the heads of which are very large. Of Northampton Hero Broccoli, Messrs. Watts & Son, of Northampton, staged some excellent heads. Of the Leamington Broccoli, Mr. Perkins showed some heads which were large, white, and solid. Baskets of excellent samples of Carter's First Crop Peas were contributed by Mr. S. Farrow, Brigadier Hill House, Enfield, and by Mr. G. Brown, Pawley Court, Henley-on-Thames.

**First-class Certificates.**—These were awarded to the following: *Sempervivum triste* (Veitch), a pretty dark-leaved kind. *Phoenix rupicola* (Veitch), a graceful Palm. *Platyloma brachypterum* (Veitch), an extremely pretty little Fern. *Platyloma bellum* (Veitch), somewhat like the former, but dwarfed. *Odontoglossum vexillarium* (Veitch), somewhat in the way of *O. Phalaenopsis*, but much larger, and of a delicate peach colour—a gem amongst Orchids. *Masdevallia* sp. (Veitch, and Denning), one of the most brilliantly-coloured of the genus—a fiery crimson. *Pelargonium White Clipper* (Denny), an excellent white-flowered zonal kind. *Colax jugosus* (Bull), a pretty Orchid, the sepals of which are creamy white, and the petals and lip striped and spotted with violet. *Begonia Sunrise* (Bull), a nice crimson-flowered herbaceous kind. *Azalea Apollo* (Turner), flowers large, white, faintly streaked with red—an excellent variety. *Auricula C. Perry*, Cantab, Rev. A. Matthews, and others (Turner). *Auricula Charles E. Brown* (Dombain).

#### MR. W. PAUL'S ROSE SHOW, SOUTH KENSINGTON.

NEVER before has such an extensive exhibition of Roses in pots as this been made by any one firm; and, tastefully arranged as they were, on the well shaven grassy terraces of the show ground, under the large tent in which the society's summer shows are held, they were seen to excellent advantage. Nor did the exhibition consist wholly of Roses, for the Queen of flowers was effectively intermixed here and there with standard Bays and *Rhododendrons*, double-flowered crimson Hawthorns, variegated and other ornamental-leaved Oaks, the white *Acer Negundo variegatum*, *Ivies* in great variety, early blooming Clematises, and in the centre stood a large specimen of *Araucaria excelsa*. By the sides of the walks were placed at intervals plants of variegated *Enonymuses*, *Golden Thyme*, *Lily of the Valley*, variegated Elders, and several kinds of bicolor, bronze-leaved, and tricolor *Pelargoniums*. A bicolor *Pelargonium* with foliage well variegated with white, and fine white flowers, was particularly remarkable, and conspicuous amongst the golden-bronze kinds was *Waltham Bronze*. The Roses consisted of large beautifully flowered specimens and intermediate and small-sized plants, but throughout the whole the blooms were remarkably large and bright, every plant being, as it were, overlaid with them; the foliage too was abundant and fine. *General Jacqueminot* and *Senateur Vaisse* were particularly striking, as was also *Duke of Edinburgh*. *Caucille de Rohan* was smothered with dark crimson velvety flowers, those of *Princess Beatrice* were large and full; and *Coquette des Blanches*, *Perfection de Montplaisir*, *Marquise de Mortmart*, and others, were likewise conspicuously beautiful.

#### COVENT GARDEN MARKET.

MAY 9TH.

Good English grown indoor fruits are somewhat scarce, with the exception of Strawberries, which are sufficient for the demand. New Grapes and Peaches have not improved since our last report. Figs and Peaches now begin to be supplied in tolerable abundance, and the first instalment of French Apricots has arrived this week. Cucumbers are good and miserably plentiful.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Apricots, 2s. to 3s. per doz.; Cobs, per lb., 2s. to 2s. 6d.; Cherries, per box, 1s. to 8s.; Gooseberries, per quart, 1s. to 2s.; Grapes, hothouse, per lb., 10s. to 18s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 6s. to 12s.; Peaches, per doz., 1s. to 3s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 8s. to 12s.; Strawberries, per oz., 9d. to 1s. 6d.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100 5s. to 10s.; French, 4s. to 8s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, young, 1s. 6d. old do., 8d.; Cauliflower, per doz., 3s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 6d. to 2s.; Endive, per doz., 2s.; Fenmel, per bundle, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz. 1s. to 2s.; Mushrooms, per pot, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 5s. to 8s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 6s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 3s. to 6s.; Potatoes, per bushel, 5s. to 10s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsify, do., 1s. to 1s. 6d.; Savoy, per doz., 2s. to 3s.; Scorzonora, per bundle, 1s.; Scakale, per basket, 1s. to 2s.; Shallots, per lb., 8d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, old, per bunch, 3d. to 6d., young do. 2s.

#### ANSWERS TO CORRESPONDENTS.

**FORGET-ME-NOTS (J. L.)**—Your plant, now blooming in profuse masses round your *Rhododendrons*, is the true *Mysotis dissitiflora*.—**ASPARAGUS (J. B.)**—Now, when somewhat warm showery weather has set in, your seeds, which have hitherto remained in the ground dormant, may be expected to start into growth.—**CROWN IMPERIAL (J. J.)**—Your specimen is a monstrosity, consisting of two or more flower heads united on the top of a fasciated stem.

## THE GARDEN.

—o—o—o—

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

—o—o—o—

### THE PURPLE BEECH AND FILBERT.

FORM, lines of grace, and curves of beauty arrest attention; but colour fills the eye and gratifies the senses. Garden scenery is brightened immensely by means of colour. The leaves of the new-born summer, the matured ones of autumn—how much they owe to delicate and multitudinous colouring! But for fresh tenderness of touch, that neither painting nor word colouring can reproduce, commend us to the bursting buds of April—the newly unrolled beauty of May leaves. Among these, what more beautiful than the Beech and the Hazel or purple-leaved Filbert? There are two or more varieties of each, one larger and of more substance than the other. In fact, of the Beech there are many varieties, for the red reproduces itself from seed, and in a batch of seedlings there are tints of many degrees, ranging from dull greens up to those of almost fiery glow. We have, however, never yet seen a seedling to equal in brilliancy the common variety, which is mostly increased by grafting it on the common Beech; and another with larger leaves, that keeps its colour later in the autumn. It must also be borne in mind that in sowing purple Beech must only a certain, or rather a most uncertain, percentage will come true and near to the original. At times ten, at others twenty, and sometimes not more than from one to five per cent. of the seedlings will be purple. We have not tried raising the purple Hazel from the nut, but probably similar results would be obtained as to the diversities of purple. But purple Filberts are easily multiplied by means of suckers—a mode of increase not always to be depended upon in purple Beeches on their own roots. Beeches seldom produce suckers, yet they occasionally throw little bunches up from the surface roots, and I have seen these green on purple seedlings, and purple on grafted plants—rather a singular circumstance. The Filbert is also so fully purpled over and through that we never remember to have seen it throw out a green sucker. It is most useful in shrubberies, contrasting admirably with such plants as Berberises, Lilacs, Laburnums, Hollies, Box, Laurels, Guelder Roses, Deutzias, &c. It seems actually to glow with the intensity of its colouring, and is to the fore and middle ground of shrubberies what the taller Beech is among other trees. The Beech has a soft fluffiness and semi-transparency about it that the Filbert, glorious as it is, lacks; and the richest colouring treat—a very feast of glowing magnificence—is spread around every far-reaching purple Beech. One of the best modes of enjoying it to the full is to put the trees between the beholder and the sun, and look through the leaves towards him soon after he has risen, or a few hours before his setting. The purple is thus flooded with golden magnificence, and each leaf and branchlet is set off to admirable advantage. Purple Beeches are especially rich as foreground to masses of green Oaks, Elms, or other deciduous trees; or set against Larches, Birches, or Limes, the light foliage of these or the flowers of Service trees, wild Crabs, Pears, Apples, &c., give a deep tone to the glowing purple. Further, the young leaves, especially, contrast admirably with Deodars and Cedars of Lebanon, and most Conifers; though it must be admitted that the darker hues of the purple Beech in autumn become too sombre accompaniments for most Pinuses. The place for the purple Beech is the background of shrubberies, home plantations, belts, the park, and even the woods and forests; for the purple Beech is not weakened by its colour. It grows as fast, and forms timber neither better nor worse than any other Beech, and assuredly its more general use would give a glow to forest scenery that would add much to its beauty, and to the breaking of its dead monotony of colour as well as form. Clumps of purple Beech here and there would change the face of our English landscapes, and render them more agreeable without their being one whit less profitable. What with our want of direct sunshine, and our

dripping clouds, and leaden skies, we have often a deficiency of cheering colour, and there could hardly be an easier and cheaper method of supplying this want than the planting our copses with groups of purple-leaved Filberts, and our woods with purple Beeches.

### THE GREAT FINCHLEY VINE.

We inspected this grand Vine a few days ago, and are glad to be able to report that it is in the finest possible health, and showing a magnificent crop of fruit. It fills a span-roofed house, some 89 feet long by 18 feet wide, the house having a sunk path through the centre, and, as Mr. Osborne very properly remarked, it would soon fill a house double the size were it only allowed to do so. The Vine is planted about the centre of the house, trained up one side of the ridge, and down the other, and from this base rods proceed right and left, at about 30 inches apart, to the ends of the house. These being trained horizontally, do not rob each other, but equalise the flow of the sap so nicely that branches and bunches are alike from centre to extremity. Some of the young shoots, though not more than a foot long, are as thick as a man's fore-finger, and, as may naturally be supposed, have bunches of proportionate size; but this Vine is not so remarkable for extraordinary bunches as for the uniformity of the bulk, none being monsters, but all of handsome size, and, when ripe, of the finest finish. The Vine is now about fifteen years old, and if proof beyond that which nature supplies in every superior tree that grows were wanting of the superiority of the extension over the trammelling system it is supplied by this noble Vine. There are many houses of fine Vines here treated upon the old system, but not one fit to compare with this plant. The only drawback upon this single plant system is the chance of injury from accident or design, and then the gap would be a wide one; but apart from that, it is manifest that in reason the more we give a Vine to do, so long as we do not overcrop it, the more it is capable of doing. Only a few days back we saw some scores of old Vine plants which we knew in vigorous health forty years ago. Last year, through the incompetence of the person in charge, most of them had to be cut down; they made fine shoots to the top of the house, and are now showing thousands of bunches. These Vines are growing in the valley of the Thames, where Vines never do wear out; indeed, to borrow a phrase from the most successful of early Grape growers, Mr. Montgomery Henderson, of Coleorton, Vines, so long as they are properly treated, never do grow old. There are some older than others, but while you treat them fairly and properly, their natural vigour will never leave them. If we want proof of this we have only to look to the trees of nature: they go on for hundreds or thousands of years, certainly not with the vigour of youth, but with an amount of accumulated strength which seems to defy old age. Young Vines, like young horses, may be quickly crippled. You may take a crop the year after planting, and continue to take mediocre Grapes for many years; but, if you want full vigour, strength to weather the storms of centuries, a Vine should be established five to seven years before it is allowed to carry a full load. In saying this much, it by no means follows that the space must be thrown away for that time. Temporary arrangements for duplicate Vines may be made; which, in the course of time, will be removed to make way for those permanent occupants which have been properly prepared. Too much stress cannot be laid upon this point by those who go in for first-class Grapes; and, if they want proof of it, let them go to Finchley.

It is not generally known that the Ash-leaved Maple (*Acer Negundo*), of which the fine variegated form is now so popular in our gardens, yields sugar. One-third more of its sap for a given quantity of sugar is required than in the case of the sap of the Sugar Maple; but then the Ash-leaved Maple yields this extra quantity of sap, and as much sugar per season per tree can be produced from it as from the Sugar Maple. The quality of the sugar is the same from both trees, but that of *A. Negundo* is a little lighter in appearance than that from the Sugar Maple. The method of sugar-making is identical with the method adopted with the Sugar Maple.

## NOTES OF THE WEEK.

— ON Monday last, at Lewestoft, the 100th birthday of Lady Smith, widow of Sir James Edward Smith, the celebrated botanist, once President of the Linnean Society, was celebrated by a dinner to 100 of the oldest people of both sexes.

— MR. B. S. WILLIAMS will send to the great flower show at Alexandra Park on the 24th inst., over 300 of the finest specimen plants from his rich collection at the Victoria Nurseries. These will remain during the following week.

— THE War Department has notified to the Council of Portsmouth that they can have possession of fifty acres of land belonging to the Crown for use as a people's park, and that as soon as a further portion of land can be spared it will be transferred. The grant was made some years since, but various circumstances have occurred to cause delay in the transfer.

— A NEW edition of the "Guide-book to the Royal Botanic Gardens at Edinburgh" has just reached us. It contains, as a frontispiece, a plan of the gardens, which will doubtless prove useful to visitors to that establishment; and the letter-press, which is profusely illustrated, will at once direct attention to most of the more remarkable objects which the gardens contain.

— ON the occasion of the recent visit of Her Majesty to the International Exhibition, bouquets of Roses, consisting chiefly of varieties raised and named after Her Majesty and the Royal Princesses by Mr. W. Paul, of Waltham Cross, were presented to the Queen and Princesses by Mr. Paul's children. The entrance to the School of Cookery was decorated with Roses furnished by Messrs. George Paul & Son, of Chesham.

— A SECOND edition of Mr. B. S. Williams's "Select Ferns and Lycopods" has just been published. It is an improvement on the first edition, both as regards illustrations and letter-press. Lovers of Ferns will find it a useful and safe guide to follow in all matters connected with the culture of that interesting class of plants.

— WALSALL is providing for itself an arboretum on a scale which will surpass anything of the kind in the whole district. This is certainly a step in the right direction. No district of equal area and population is, perhaps, so destitute of public recreation grounds as the Black Country. Indeed, were it not for the Dudley Castle grounds, which Lord Dudley now generously throws open, of public parks in South Staffordshire there would be none.

— ONE great fault of the massing system of bulb-growing is well seen in Hyde Park, near Park Lane, just now. The Hyacinths having all gone out of bloom at nearly the same time, the vast line of beds devoted to these plants has been worse than a blank for some time past. Any system of gardening which leaves such a large strip of flower garden as that along Park Lane a perfect blank in the month of May, or at any other time, must obviously be bad, from the point of view of the artistic gardener. This strip of garden along Park Lane is at once the most costly, and, as regards design, the most inartistic example of flower gardening that we know of.

— WE observe that *Mesembryanthemum aureum* has been planted in quantity in the flower-beds beneath some standard trees in Hyde Park, between Albert Gate and Hyde Park Corner, and that when the sun is shining its flowers are very effective. We, however, prefer the brighter coloured *M. aurantiacum* to *aureum*, and such of our readers as are fond of contrast might also like to add the crimson-flowered *M. splendens*, the bright red *M. conspicuum*, or the purple blossomed *M. inclaudens*, all easily managed plants, which come into bloom after Hyacinths and early Tulips are over, and which maintain a considerable amount of gaiety at a time when beds would otherwise be comparatively uninteresting.

— A REALLY good blue-coloured bedding Pansy has long been a desideratum; it may, however, now be found in Messrs. Downie, Laird, & Laing's Blue King, which may be seen at present in full bloom in their nursery at Forest Hill. The flowers of this variety are of fine form, are produced in the greatest possible profusion, and are of a deep vivid blue colour, with a bright and conspicuous yellow eye. Compared with Clivedon Blue and Imperial Blue, beside both of which Blue King is growing, its superiority over both sorts, as respects size and beauty, may be readily recognised even at a distance, and it continues to flower throughout the entire spring, summer, and autumn months without intermission. It throws up its flowers, too, more uniformly than its associates, and it is neither liable to sport nor to be scorched by the summer's sun.

— AMONGST a recent importation of roots of *Todea superba* by Messrs. Rollisson & Sons, Tooting, there has arrived a kind which appears to be a hybrid between *T. superba* and *T. pellucida*, as it possesses characteristics precisely intermediate between these two species. Under the kind of treatment usually given to filmy Ferns,

this supposed hybrid has started vigorously into growth, and is now one of the largest and most handsome specimens of the filmy *Todeas* in the country. It is furnished with some four dozen well developed and perfect fronds, covering a space of 4 feet in diameter. It is kept within a glass case 3 feet 9 inches in diameter, and being raised a little in the case, its gracefully drooping fronds are seen to excellent advantage.

— SOME fine Tomatoes from Algiers have made their appearance in Covent Garden market, during these last eight or ten days. They are large, well coloured, and beautifully ripened, and, notwithstanding their sea voyage, have arrived in good condition, and keep soundly for several days after being imported. They sell for about a shilling apiece.

— A GARLAND show took place in a field at Stamford the other day, at which thirty prizes, varying in amount from 16s. 6d. downwards, were awarded to juvenile exhibitors from different parishes of that town. A band of music was provided for the occasion, and, after the prizes were awarded, some 500 children were regaled with tea and cake. The day being fine, nearly £15 were taken at the gates.

— ALEXANDRA PALACE, of which we give an illustration in our present number (see p. 386), is to be opened on the 24th inst., when there will be, in addition to a great flower show, a grand concert, conducted by Sir Michael Costa. Many will be glad to learn that at last there is a chance of this spacious building and beautiful grounds gaining public support, and thus becoming secured as a place of popular recreation.

— MR. WILLIAMS' large new Violet Sensation, now in perfect bloom in the Victoria Nurseries, Holloway, is one of the finest things in its way we have seen. It is intermediate in character, between a good Violet of the Cornuta race and a blue Pansy, and has the early blooming character of the Pansies.

— It appears that John Stuart Mill, whom we have just lost, was passionately fond of botany, and that his love for natural scenery was intense. It has been his habit, in later years, after a period of the closest application to work in his home at Avignon, to break away, into some new and less frequented field of travel, to collect plants, and, after toiling along on foot under a hot sun, to recount with the simplest enthusiasm what new kinds he had picked up by the way, and what new impressions, grand or beautiful, he had received from the face of nature. This delight in natural scenery came out even in the midst of the driest economic discussions.

— AT the meeting of the Royal Horticultural Society on Wednesday next, there will be an interesting exhibition of stove and greenhouse plants, grown under special conditions. Two years ago a gentleman gave to the society a sum of money for special purposes, and the Council, under the advice of Mr. Marshall, resolved that it should be given for twenty-four plants selected by the exhibitors who paid an entrance-fee of £5 each, and decided that they should show eight plants each at the last May meeting of the society. By some inadvertence the competition has been entered on the schedule for June 4th, but the exhibitors have prepared their plants for May, and insist upon showing their collections according to the original conditions. We have seen some of the competing plants, and are glad to be able to say that the art of superior plant growing has not died out, but that, on the contrary, some superb plants will be presented.

— THE authorities of the city of Paris are considering the advisability of removing the admirable establishment of the "city gardener," in whose forcing-houses, conservatories, and beds the millions of plants and flowers which decorate the public gardens and promenades of Paris are reared, and the more delicate stored in winter, from La Mnette to Neuilly. It seems a pity to disturb so well-arranged an establishment as that in question; and considering the number and size of the horticultural buildings, it will be a costly business, but it appears that the land at Passy is in demand at high prices for the erection of new villas, while the city possesses a larger site in the Parc aux Princes at Neuilly, which has failed to attract the Parisians.

— LAST year's report of the Eyemouth and Paxton School Gardens, Berwickshire, is worth the attention of everybody in any way connected with Industrial Schools. The Eyemouth Garden contains, it is stated, 850 square yards (28 perches, 3 yards), divided into ten plots, or small gardens, each cultivated by a single boy, from twelve to sixteen years old. The profits from this small patch amounted in the gross to £7 4s. 6d., being at the rate of £4 13s. per acre. The Paxton Garden contains 497 square yards (16 perches, 13 yards), divided into five plots, and each plot, as in the case of the Eyemouth Garden, is cultivated by a single boy. The united profit from this garden last year was £2 11s. 8½d., or at the rate of £25 1s. per acre. These boys, who have had gardens from one to two and four years, grow Cabbages, Potatoes, Shallots, Onions, Leeks, Greens, Cauliflowers, and Rhubarb.

## THE ARBORETUM.

### HARDY TREES AND SHRUBS.

BY GEORGE GORDON, A.L.S.

THE ACUTE-LOBED MAPLE (*ACER ACUMINATUM*).

THIS forms a fine, erect-growing, deciduous tree, from 30 to 40 feet high, with erect branches, and rather long, slender, smooth, glossy shoots of a reddish colour. It is a native of Upper Nepal, in Sirinagr, where it is called "Khainsing," and was first introduced in 1845. It is quite hardy, and grows freely in any good garden soil. It is easily increased, either by layers or by means of cuttings made of the half-ripened shoots in the autumn. The leaves are of medium size, either three-lobed or visibly five-lobed, doubly serrated on the edges, cordate at the base, smooth on both surfaces, deep green above, and set on not very long footstalks, and they are retained on the tree until destroyed by the autumn frost. The lobes are oval, with long, tapering acute points, and unequal in size, the middle one being much the largest, and doubly serrated. The principal ribs and veins on the under side are very prominent, with the centre one straight from the footstalk to the tip of the outer lobe. The flowers are greenish white, and are produced in April in axillary, erect, few-flowered corymbs along with the young leaves. The keys or fruit are smooth, with thick carpels and oval wings, rather spreading. The length of a full-sized leaf is 6 inches, including the footstalk, which is from 1 to 1½ inch long, and the breadth is about 3 inches.

#### The Laurustinus as a Cottage Wall Plant.

While passing along a country road the other day, I was struck with the beauty of a cottage front clothed with Laurustinus, which at a little distance off looked exactly like a white Ixora. It was neatly trained and profusely flowered, and looked beautiful in the distance. It is one of the best plants for a cottage garden, and also for the bottoms of cottage walls, and the clothing of outhouses with evergreen beauty, producing a harvest of pinky white and pure white blossoms from Christmas to May. Perhaps, however, the shining-leaved variety is the best for this purpose; but all Laurustinuses are beautiful, and they are easily grown and readily propagated. They are also useful for cutting, and for contributing to the filling of vases and the making of bouquets, and are often used extensively for the base work of wedding and other bouquets. For a cottage parlour table who could wish for a nicer bouquet than a base of Laurustinus crowned with bunches of Violets? Or, later in the season, single Moss or monthly dark China or pink Roses or sprays of Ribes or dark Wallflowers displayed over or arranged amongst it?—D., *Bury*.

**Forsythia viridissima.**—This, though one of the brightest of early spring-blooming hardy shrubs, is not nearly so much grown as it deserves to be. Like *Jasminum nudiflorum*, the flowers come before the foliage, and continue in great beauty a long time. Unlike many early flowers, cutting winds do not seem to have much effect upon its duration. I don't think I have ever seen it more bright and beautiful than it has been this spring. It is very handsome, either as a single cone-shaped specimen, supported by a stent stake or pole

in the centre, or as dwarf masses nearer the edge of the shrubbery. It requires a little attention with the pruning-knife once a year after flowering, and any gross shoots that appear afterwards may be advantageously pinched in. By this means a neat compact outline may always be preserved. In addition to its usefulness in the shrubbery, it is a capital plant for quickly covering a naked wall, clothing it, as it were, through a good portion of March, April, and well into May, with a sheet of bright gold. We have two plants here, one on either side of a doorway in the garden wall, that must have been years ago at the top of the wall. I believe there is scarcely any limit to the height it will grow in moderately good soil. Neat bushes of it also, in pots, make useful and very desirable plants for the conservatory in mid-winter, coming into bloom early, without much forcing, if the wood has been previously well ripened. It is easily propagated by cuttings of ripened wood in September, under the north side of a fence. I once made a lot of cuttings in the autumn, and they were laid in deeply in bundles, till a favourable opportunity for planting arrived. Well, a pressure of other matters occurred, and the cuttings were left till April, and when examined, most of them were callused, and many had emitted roots. I mention this merely to show that with cuttings of this and similar things it is important for the cutting to be taken off early in autumn, and

properly made with a sharp knife; when, if not finally planted for several months afterwards, they will take no harm, as the work, preparatory to rooting, is being silently carried on under ground, and it is work that cannot be hurried. One reason why a good many cuttings of shrubs, Roses, &c., fail when put in by amateurs is, they are taken off too late; nature has not time to perform her work before the period arrives for the sap to ascend.—E. HOBDDAY.

*Acer acuminatum.*

worth, which made small trees from 10 to 15 feet high, and with stems from 1 to 2 feet in circumference. He was entirely satisfied that it is identical in every respect but size with the *Q. prinoides* of the Eastern States. Among trees there are few which produce forms as low shrubs, but the *Pinus Banksiana*, in the East but a bush of 5 or 10 feet, grew often 40 feet along the shores of Lake Superior; the *Castanea pumila*, Chicknapin Chestnut, when it gets out of the sands of New Jersey into the clayey soils west of the Delaware, often grew as large as many full grown Apple trees; while the *Celtis occidentalis*, which in the East is generally but a straggling bush along fence corners, is in Ohio a large spreading tree with an enormous trunk, and in Indiana is as lofty and as graceful as an Elm.

#### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Cistuses for the Wild Garden.**—At Heatherside these brilliant shrubs are found to thrive freely in the "wilderness," no doubt owing to the free open soil; and what glorious additions to the wild garden!—W. R.

**Large Tulip Trees.**—The largest Tulip tree I ever saw was on Col. Ambler's estate, in Virginia. It was 210 feet in height, and the trunk, which was branchless for 100 feet in height, was 42 feet in circumference at 5 feet from the ground, the spread of the branches being 150 feet. This tree was killed by lightning in 1856. I have measured trunks of other Tulip trees in Virginia, and have found them over 36 feet in circumference. In England the best Tulip tree I have seen is at Fulham Palace.—JOSEPH NEWTON.

## ANCIENT EMPLOYMENT OF FLOWERS.

THE words "copa narium," which "W. M." (see page 328) adduces as proof that I am wrong in saying that there is no allusion in the classical Latin authors to bouquets, have nothing to do with the argument. They occur in the 15th ode of the 2nd Book, this particular ode being playfully levelled at the constantly-increasing luxury of the Roman nobles, a result of which growing luxury, he says, will be that, in a little while, palaces and ornamental waters will occupy all the land that once was devoted to farming purposes, and that "the Olive plantations, once so fruitful to their owner, will be superseded by banks of Violets, Myrtles, and other plants, in all their plenteousness, that are delightful to the nostrils."

Tuna violaria et  
Myrtus et omnis copa narium  
Spargent olivetis odorem  
Fertilibus domino priori.

The passage cannot be translated in fewer words, so as to convey a full and proper sense of its meaning to persons not acquainted with Latin. In what possible way can it be tortured into a disproof of what I have said? My assertion is, that bouquets are not mentioned; "W. M." points to a jocular allusion to possible plantations of odiferous shrubs and herbs! The second argument brought forward by your correspondent to prove that the ancient poets make allusions to bouquets is, that he ("W. M.") "cannot rationally conclude" but that the Roman youth must have worn such things. But where is the remotest allusion to such a practice to be found? The poets' allusions are the things desired, not guesses and speculations, unsupported by a tittle of evidence. And upon what ground does "W. M." build his surmise that we do not possess a full glossary of Greek and Roman colloquial words? Is he acquainted with the writings of Aristophanes, Athenæus, and Petronius Arbitrator? Thirdly, "W. M." considers that Virgil's comparison of the premature death of the youth Pallas to the snapping of the peduncle of a flower by a thoughtless girl, is "an allusion to bouquets"! Why did he not quote at the same time the gathering of the flowers by Proserpine, when she was at play with her companions in the fields? He goes on to say that the simile in question "so sufficiently confutes" my "not well-considered notion," that he need not pursue his remarks. Will "W. M." have the kindness to "pursue his remarks" immediately, in the shape of even a single quotation from any classical Greek or Latin poet in which a bouquet is mentioned; will he give us even the corresponding Greek or Latin word? If I am wrong I shall be only too thankful to be set right. Meantime I cannot consider that my statement is disproved. Will "W. M." kindly intimate what flowers Virgil intended by *Viola* and *Hyacinthus*? Of course he is well aware (at least I hope so) that with the ancients these names did not apply exclusively (if in Virgil at all) to the botanical genera which bear them at the present day.

LEO GRINDON.

**Sweet-scented Flowers.**—Mr. Grindon's remarks on flower odours (see page 319) will take thousands by surprise, especially those sticklers against plants and flowers in rooms who would not have one for the world, for fear some delicate person might "die of a Rose, in aromatic pain." Still there are those to whom what are called sweet scents are positively offensive. My object, however, is not to plead for sweet flowers, but to suggest how, at a small cost, we may command them in quantity. When employed in Nottingham, my residence was on the outskirts of the forest, and consequently, in going to my office, I had to pass scores of gardens. A whiff of Mignonette here and there determined me to have more of it, and consequently, in the following spring, armed with a few ounces of seed, I threw a pinch into almost every garden that I passed, thus taking a summary way of furnishing them with sweet flowers. I threw the seed over the fence, feeling convinced that the plants, when once recognised, would not afterwards be banished. My scheme succeeded, and for a few pence I was rewarded with miles of sweet odour. Let others go and do likewise, and they will be unawares sowing miles of ozone, pure oxygen, health and happiness for thousands. I am amazed that sweet flowers are not more widely cultivated in our public promenades and gardens than they are. A word to the wise, I trust, will be sufficient. If I used a public path, I should, so far as sweet annuals are concerned, take care of myself.—A.

**Antiquity of Flax.**—Dr. Oswald Heer, of Zurich, has published a paper "On Flax Culture in Pre-historic Times." He finds the original home of the Flax to be along the shores of the Mediterranean. It can be shown that the plant was cultivated in Egypt 5,000 years ago. Flax is found among the remains of the oldest pile-dwellings in the Swiss Lakes, where neither hemp nor wool has been discovered; and it is probable that the old lake-dwellers received the Flax-plant from the South of Europe.

## THE INDOOR GARDEN.

## PLANT GROWING FOR MARKET.

LOOKING at the immense area of London and its suburbs, its myriads of houses, and almost countless flower-loving population, there is little need for wonder that such large quantities, both of plants and cut flowers, should annually be swallowed up by it, or that plant-growing establishments on a large scale should be required to supply its wants. Of these, one at Feltham, carried on by Mr. Henry Bailey, deserves more than a passing remark. This was established some twenty-five years ago by the late Mr. Catleugh; but, under Mr. Bailey's five years' proprietorship, it has increased in importance considerably, producing tens of thousands of plants and cut flowers annually. A huge span-roofed building constitutes the "finishing" house for *Fuchsias* and show *Pelargoniums*, and there are some two dozen other span houses, averaging 80 feet long, and 14 feet wide, all heated by Weeks's tubular boiler. Each house is supplied with a capacious water-tank, and these tanks are all connected by means of pipes leading to a large tub that is placed on a platform close to a pump—an arrangement by which the whole of the houses can be readily supplied with water. Starting with the beginning of the year, the plant season might be said to commence with *Primulas*, *Cyclamens*, and *Lilies of the Valley*. Then come *Cinerarias*, *Hoteia* (*Spiraea japonica*), show and fancy *Pelargoniums* and *Fuchsias*, which constitute, with *Hoteias*, *Lycopods*, &c., the bulk of the plants now ready for market. With the excellence of Mr. Bailey's *Pelargonium*-growing most people are acquainted, as when at *Shardloes* he exhibited at our great metropolitan shows some of the best grown and flowered *Pelargoniums* ever staged. Those at Feltham are in 48-sized pots, yet they are full of foliage, glossy, green, and healthy, and carry heads of eight, ten, and twelve trusses of flowers. The kinds most in request and best adapted, both for forcing and market work, are show sorts, such as *Minnie*, *rose*; *Wm. Bull*, *crimson scarlet*; *Belle Blanche*, and *Albion*, white; *Mrs. Lewis Lloyd*, and a few unnamed seedlings. Of these varieties, from 10,000 to 12,000 are grown each year, and in order to keep up the stock the process of propagation commences as soon as the smallest cuttings can be obtained, and is maintained incessantly all through the summer. In the various houses *Pelargoniums* may now be seen in different stages of growth, but by far the larger proportion of them are rapidly approaching the blooming period, in close succession. The essential points as regards culture are, cleanliness, a position near the glass, and a never-failing supply of water. The compost used is good rich loam, and a fair admixture of very rotten manure. Occasional doses of liquid manure are also given after the flower-buds have appeared. The old *Pelargonium* *Gauntlet*, a reddish-scarlet, is largely grown here for winter-blooming; it forces admirably, and furnishes a large supply of flowers fit for cutting from October to March. Of fancy *Pelargoniums*, such kinds as *Princess Teck*, *Fanny Gair*, *Lucey*, *Aeme*, and one raised many years ago, called *Princess Marie*, are grown in quantities, and the heads of flower which they produce, combined with dwarf robust growth, excite one's admiration. These require neither stopping nor tying, and some 2,000 are sent to market annually. Marvellous examples of the *Hoteia japonica* are produced in hundreds in 48-sized pots—charming plants, 24 inches high and as much through, each bearing a dozen spikes of bloom. These are raised from roots of continental growth, potted up in November, plunged in cold pits in a bed of rotten tan, and sheltered from heavy rains until they burst their crowns about January, when the earliest batch is pushed on in gentle heat, the remainder following in succession in cool houses. Such moisture-loving plants are these *Hoteias* that on dry sunny days they want water four times a day, those growing in heat being also set in saucers.

*Fuchsias* are grown in immense quantities, especially that excellent light variety known as *Mrs. Marshall*, of which capital plants may be found here 18 inches high and 12 inches through, beautifully in flower, fully foliaged, and growing in 48-sized pots. One large span-roofed house is devoted, as I have said, to the "finishing" of this variety just now, and other kinds will shortly follow for summer decoration. *Mrs. Marshall* must of necessity be frequently "pinched" while growing, but *Lady Heytesbury*, a favourite white kind, is best if left alone, naturally forming very speedily of its own accord a neat little pyramid. *Souvenir de Chiswick* and *War Eagle* are both useful red kinds for market purposes. The best *Heliotrope* is *Florence Nightingale*, a good dark kind; and the finest of all the scarlet *Zonal Pelargoniums* for cutting flowers from in winter is *Vesuvius*, of which many hundreds are grown. *Maidenhair Fern* is in large demand for cut fronds, and of *Lycopodium denticulatum* some 8,000 pots are disposed of annually. The stock plants of this are grown on a border in one of the large houses, and portions of them are being continually taken off, struck, and potted up into 48-sized pots; the soil, which must be light and porous, consists of peat and leaf-mould. Grown as at

Feltham, in a somewhat shaded house, in a gentle heat and with plenty of moisture, good established plants fit for sale are obtained in about three weeks.

For cut flowers, which are always in demand, a lot of fine Tea Roses is grown in pots; also Fielder's White Azalea, which is one of the best for forcing. Gardenias, Vallotas, and the Narcissus Poeticus, the latter being most successfully managed in pots by putting about twelve bulbs into a 32-sized one, and plunging them out-of-doors until they start, when they are lifted and forced in gentle heat; established roots of this Narcissus usually do better the second year than the first. In several houses Stephanotis is planted out and trained along the roof, a position in which it makes wonderful growth and yields an abundance of flower. Nothing is more evident than that this beautiful climber needs plenty of space both for root and top, and that under such conditions it will grow as fast as hops.

A. D.

## A SINGULAR BROMELIAD.

TILLANDSIA REVOLUTA (*pro tem.*).

Now that succulent plants are again coming into public favour, a few words descriptive of a new, or at least undetermined,

A New Bromeliad (*Tillandsia revoluta*, *pro tem.*) one-third natural size.

*Tillandsia*, may be of some interest. We have not many species of *Tillandsia* in cultivation, though some of them do remarkably well if treated like Orchids and other tropical epiphytes. *T. argentea* is one of the most valuable cultivated species, and is also very rare. Its silvery foliage is its chief attraction. *T. usneoides*, a species from the West Indies, is very peculiar in its habit of growth. It may be seen growing on several plants in the Royal Gardens, Kew, and looks very much like a bunch of dried Grass or Sedge. The present South American species comes from a strip of forest about three miles from Campo Coronta—*i.e.*, the Crowned Camp—a small cattle station on the river Parana, in Corrientes, thirty miles from Goya. This place may be reached *via* Buenos Ayres, from which it is distant some six hundred miles. This and several other Bromeliads are found on the trees in this vicinity in tolerable abundance, in company with scandent Polypodiums and other epiphytes and sub-terrestrial plants. It appears to be a plant of free growth, and has leaves which vary from 3 inches to a foot in length. From the quantity of old flower-spikes on imported plants, it is evidently a profuse bloomer, though it is questionable whether the flowers are of very great beauty. The most peculiar point about this plant is its leaves,

their margins being involute, while their apices are decidedly revolute and prehensile. They may not inaptly be likened to the caudal appendages of certain *Quadrumania*, since they clasp any branchlet or twig within their reach, and thus suspend themselves firmly in their aerial habitats. These leaves are of a velvety texture, and of a bright silvery colour; indeed, it is a worthy rival to *T. argentea*, and far more interesting. In all probability the first living plants imported to this country were obtained by Mr. Gaylard Hadwen, though the plant has existed in herbaria for some considerable time. Mr. J. G. Baker considers it near *Tillandsia rubra*, R. and P.; and the same plant, or one nearly identical, may be found in Mandon's Peruvian Collection (No. 1,185). As a provisional name, I would suggest *Tillandsia revoluta*. F. W. BURBIDGE.

*Cobæa scandens variegata*.—Allow me to add the name of this very desirable plant as a conservatory climber, to those recommended by your correspondent Mr. Dick (see p. 334). This is certainly a most valuable plant for the purpose just named, being exceedingly ornamental, of rapid growth, and it enjoys a perfect immunity from the attacks of insect pests of all kinds. Unlike most variegated plants, the condition of variegation has little if at all diminished its vigour or growing powers. It is admirably suited for training up pillars and for festoons under the roofs of the most lofty conservatories, and the distance it will grow in one season is truly astonishing. It must, however, have abundance of root room, and the system recommended by your correspondent of keeping the roots outside the structure is exactly the treatment which it requires.—P. G.

**Cowan's Heating Apparatus.**—In my notice of Mr. Cowan's ingenious and entirely novel system of heating horticultural buildings, you have interpolated the observation that "the system is not quite new." I firmly believe, however, that in a simple and practical form, suitable to structures of any dimensions, the very perfect and ingenious system of Mr. Cowan is without a predecessor; notwithstanding that rude experiments upon an analogous principle, ending in failure, may possibly have been attempted, although I have never heard of them. I trust that in justice to Mr. Cowan's excellent system, and to my own careful observation of its working (which extended over several days) you will give immediate insertion to this letter.—H. NOEL HUMPHREYS. [What we meant was that the application of lime-kiln heating to horticultural buildings had been tried before; not that Mr. Cowan's particular, and as it proves, excellent plan of carrying out the system was not new.]

**Balsams.**—These require—Firstly, all the light our climate affords, which suggests clean glass, and that the plants, during all the stages of their growth up to blooming, should be kept as near it as is practicable. Secondly, a rich open compost to grow in, through which the roots will readily ramify, and rich enough to furnish them with food sufficient to keep the top growing freely; the great demand made on the roots during the period of active growth informs us that liquid manure is a useful auxiliary to keep up the vigour of the plants, and may be applied freely when the pots become full of roots. Thirdly, bottom heat; to give every encouragement to a free growth, the application of a mild bottom heat from the first stage of the plant's growth till the bloom-buds are formed should be maintained; when the buds are duly formed, and any further extension of growth unnecessary, the bottom heat should be allowed to die gradually away, so as to harden the plants, to bear the comparatively cool temperature of the conservatory for blooming. Fourthly, air during every stage of growth; the Balsam requires a large supply of air, that the plants may not become drawn and slender, but kept short-jointed and stocky in habit, which will enable the lateral branches to support themselves without stakes until the blooms expand, when they will be required.—M.

## NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Tree Carnations.**—How am I to treat some plants of these that have become what is termed "lanky"?—W. S. [Train them round four sticks, or other kind of trellis, keeping the shoots as low as possible, and place the plants in the open air during the summer months.]

**Abutilon Boule de Nègre.**—Just imagine a pure white *Abutilon*! really snow white, and as large as *A. striatum*. Such an one has just been introduced from the South of France, by Messrs. Standish & Co., of Ascot. It can claim some degree of hardihood, for at Caen, in the South of France, it has successfully withstood the winter growing in the open air. It is a fine bell-shaped variety, blooming with great profusion, and throwing its cluste bell-shaped blossoms outside the leaves. As a conservatory plant it is a great acquisition; it will be gladly welcomed by sub-tropical gardeners, and it is said to be of great value for bouquets.

## THE FRUIT GARDEN.

### FRUIT PROSPECTS.

THE first of May set in here with a soft south-west breeze and a genial temperature, very different from the cold, piercing, sharp east winds experienced during the previous ten days, and already our hopes are high that good crops of Plums, Pears, and Apples will be realised. Our early crops of Strawberries have been a signal failure as regards flavour. We had fruit set and swelling early in March, but there was no sun and no light, and a dense fog frequently enveloped everything. The fruit was of fair size but tasteless and without colour. President, Keens' Seedling, and Count de Zane (a variety much prized in this neighbourhood) were a greenish white. April, however, brought us good gatherings of these varieties, and good-sized fruit. During the fog, or what may be termed "the dark season," early Vines showing fruit suffered more or less; tendrils lengthened, and the embryo bunch had a tendency to elongate more than was necessary; but as the air cleared this state of things altered, and the principal crops of Grapes are now all that could be desired. Early Peaches and Nectarines have gone on all along well, and are now swelling off one of the best crops we have gathered for years. Those under glass covers are now setting, and are likely to prove as good as heretofore. Plums, Cherries, and Pears grown under similar circumstances are also very promising. The snow and frost of April 25th did considerable damage to a few of the early Gooseberries, and to such blossoms of Plums, Pears, and Peaches as were expanded in warm, although exposed, corners; but the principal crops are still safe. Apples, both in the garden and orchard, in a few days will be one mass of blossom.

*Southend Gardens, Darlington.*

JOHN RICHARDSON.

### RENOVATING A FRUIT AND KITCHEN GARDEN.

SOME remarks have lately appeared in THE GARDEN (see p. 119) on this subject. If the garden to be renovated has been much neglected, it will be a matter to consider whether it will not be best to sweep the fruit trees clean away, and begin afresh, or whether among them there may be some that may be worth retaining. Of course much will depend upon the kind of trees that have to be dealt with. No man would think of destroying a decent tree of any good kind of Apple, Pear, or Plum, until such time as young ones had been reared in a bearing state to take their places. To replace a Greengage Plum, Ribston Pippin Apple, or Gansel's Bergamotte Pear, is no easy matter, for I have always found that an old thoroughly established tree, of any of these kinds of fruits, will produce much better flavoured specimens than the most healthy young plants. This arises no doubt from the maturing principle having been more fully developed, or in other words there is less water in the composition of the tree than in a young specimen which may be considered as only in process of development. Of course much of the flavour of a fruit depends upon soil, situation, and growth, but all things considered I believe it will always be found that old established trees impart more flavour to their produce than young growing ones. Thus I almost reverence an old Greengage Plum, and I have much respect for an old Ribston Pippin Apple. The decision being made as to what trees shall be retained, the first work of the improver will be to clear away those condemned, grubbing them out root and branch; then carefully prune and thin out the branches of the trees retained, so as to allow the air and light to sweep freely through the interior. I once found a Blenheim Orange Apple growing in a garden from which I cut away sufficient wood to make twenty-five large faggots, and the following season the tree produced about ten bushels of the finest fruit of the kind I ever saw. Not a fruit was less than eight ounces in weight, and many of them more than a pound each. The advantage of pruning old crowded fruit trees cannot be overrated. If trees are properly managed, the branches should never be allowed to cross, neither should the inside of the trees become crowded with wood. Numerically, so allowed to run to waste, a large quantity of fruit may be produced; but, subjected to the market test of price, or the cook's test of quality, it will always be found that well-grown fruit is much more valuable than a larger quantity of inferior produce. Well, the trees being pruned, and the bark cleaned of Lichens, Moss, and insect pests, the next thing to be considered will be the ground. If it has not been thoroughly drained, or if the old drains are not in good working condition, it will be best to put in new ones. These, for a kitchen garden, should not be less than 4 feet deep, and should be formed of 2-inch tubes neatly fitted together at the joints. If at hand, a turf, Grass side downwards, some Couch roots, small branches, or straw may be thrown over the pipes before the soil is filled in. Some object to this practice, but I think it is a protection, and prevents the pipes being disturbed when tilling in the soil; and, moreover, it forms a rough filter for the water to pass through. For

a kitchen garden the drains should not be more than 18 to 20 feet apart if the soil is light, but if heavy, 15 feet apart will be much better. The extra cost of an additional drain is not much compared with perfect efficiency of the work. Of course many will object to deep and frequent drains. Well, let them do so. When I see shallow ill-drained soils produce finer crops than deep well filled ground, then I will change my opinion. Until then I must advocate deeply-drained and deeply-trenched ground for all permanent improvements of the soil. The thicker the sponge above the drain the larger the quantity of moisture it will hold, and consequently the larger the quantity that will be available for the roots of the plants when dry weather sets in. Of the correctness of this assumption I have had ample demonstration in almost every county in England. The Lois Weedon system of cultivation, which was so successful while it was carried out, consisted in deep draining and deep cultivation without manure, but many cannot see, and others will not see, the advantages of such a system. Putting aside the advantage of deep cultivation in the field, there can be no question respecting its advantages in the garden. All, I think, are agreed there, and the best gardeners would like to go a little deeper if they could. I, therefore, pronounce 3 feet to be a minimum depth to which the soil of a garden ought to be stirred, not necessarily bringing the bottom soil to the top, but placing it so as best to serve the purpose in view. Thus, if I had good soil to the depth of 2 feet, I would, in an old garden, completely reverse it to that depth; but if the subsoil was of inferior quality, I would leave it there, breaking it up to the depth of a foot, either with a pick-axe or Parkes's steel fork.

For the improvement of an old garden soil I have much faith in the use of salt, and if lime and salt can be mixed together, so much the better. Most plants like salt, when used in moderation, and such things as Asparagus and Seakale, seaside plants, will take any reasonable quantity of it. Of this I should not hesitate to use 3 cwt. per acre, thrown over the ground after trenching, as I should expect it to be washed far away from the plants long before they could be injuriously affected. Supplement salt with lime, and you can scarcely make a more healthy preparation of the soil for planting. Lime upon an old soil, especially one rich in vegetable matter, can scarcely be used in excess. We do not use lime nearly so plentifully as we ought to do in our gardens, and the consequence is the land gets sick of the enormous quantity of manure which we give it. In fact it becomes sour, vegetables grow rank, but ill-matured, and hence have not the flavour as when the ground is thoroughly healthy. No person who has been using manure liberally can do wrong in giving a good dressing of lime, more especially if the land is heavy. Upon light soils it may be wise to use it more cautiously. One word more: I would advise the walks and every part of the garden to be trenched so that the trees may make use of the good soil under them. Of course the material of the walks can be preserved, but before it was used again I should take care to work a liberal supply of lime and salt into the subsoil.

A.

### THE FLOWER-DE-LUCE.

BEAUTIFUL Lily, dwelling by still rivers,  
Or solitary mere,  
Or where the sluggish meadow-brook delivers  
Its waters to the weir!  
Thou laughest at the mill, the whirl and worry  
Of spindle and of loom,  
And the great wheel that toils amid the hurry  
And rushing of the flume.  
Born to the purple, born to joy and pleasure,  
Thou dost not toil nor spin,  
But makest glad and radiant with thy presence  
The meadow and the lin.  
The wind blows, and uplifts thy drooping banner,  
And round thee throng and run  
The rushes, the green yeomen of thy manor,  
The outlaws of the sun.  
The burnished dragon-fly is thine attendant,  
And tilts against the field,  
And down the listéd sunbeam rides resplendent  
With stell-blue mail and shield.  
Thou art the Iris, fair among the fairest,  
Who, armed with golden rod  
And winged with the celestial azure, bearest  
The message of some god.  
Thou art the Muse, who far from crowded cities  
Hauwest the sylvan streams,  
Playing on pipes of reed the artless ditties  
That come to us as dreams.  
O flower-de-luce, bloom on, and let the river  
Linger to kiss thy feet!  
O flower of song, bloom on, and make for ever  
The world more fair and sweet. — *Longfellow.*

## GARDEN DESTROYERS.

THE VAPOURER MOTH (*BOMBYX (ORGYIA) ANTIQUA*).

It would seem lost labour for an entomologist to attempt to collect in the streets of London, but the ground is not utterly barren, and a list of species taken thence would furnish material for much interesting cogitation. It is not our business to go into that enquiry now; we only wish to draw attention at present to one of the species which would come into that list, and which may be pre-eminently called a Cockney insect—the Vapourer Moth, or *Orgyia antiqua* of entomologists. The caterpillar (which is one of the most remarkable and beautiful of the hairy caterpillars), is to be found in every square in London, and the male is to be seen dashing about in the streets, from right to left, during summer, and especially frequent towards the beginning of autumn. Its flight seems a series of reckless and purposeless vagaries, but it is not so destitute of meaning as it looks like. It is busy peering, or rather seeking with its large plumose antennæ in every direction in search of the female. She, however, is not to be seen flying about. No pairs are ever seen tilting and

The Vapourer Moth.

flirting in the sunshine. In all his airy sports and rambles the male has no companion; in that respect his wife might serve as an example to our frivolous or fast girls of the day, although they might retort that she has little merit in not gadding or flying abroad, seeing that she cannot fly, and that her abstinent, staid, and proper demeanour is thus compulsory.

The male is a pretty moth, with wings of a reddish-brown colour, and two sinuous transverse bands of a darker colour, of which the outer and larger terminates in a lunule of a pure white. The under wings are yellowish red. The female, although she cannot fly, is not absolutely without wings. She has very small stumps of wings, which require to be sought for to be found. She is about a quarter of an inch in length, and of a rather dark grey colour. Both sexes are represented in the accompanying woodcut. The insect has usually two main broods, but towards the end of the season the broods become confused, there being apparently a continuous succession of generations—eggs, caterpillars, and perfect insects being to be

found at the same time and together during the whole of autumn. The eggs of the first brood are laid at the beginning of winter, and remain unhatched until the end of spring. The caterpillars of the first brood come out of their eggs about the beginning of May, and the perfect insects from them appear about the end of June and beginning of July. Of the second brood, or succession of broods, the caterpillars first appear in the end of July and in August, and the perfect insects in September, and onwards until winter. The caterpillar is very common in the autumn, and there is scarcely a plant on which it will not feed, but it more particularly affects fruit trees and Rose trees; it varies in colour, being sometimes of a very pale bluish grey, sometimes blackish, and sometimes whitish, with tufted greyish hairs implanted on the tubercles with which it is furnished. The first segment has, on each side, a long bundle of unequal hairs, each terminated by a little knob, which when united look like horns; near the tail the eleventh segment has a similar bundle inclined backwards, the fifth segment (a little before the middle) has also one on each side directed outwards. The fourth, fifth, sixth, and seventh segments have each on the middle of the back a double brush of hair without knobs at the top, of equal length, sometimes white, sometimes grey, sometimes yellow, often red, and sometimes blackish. On each side of the body there is a range of red tubercles supporting the little aigrettes. On the back the spaces between the segments bearing the brushes are black. From the last brush until the tail the colour becomes deeper, and presents on each ring two red tubercles in a line with those of the lateral range, forming a semi-circular band. The first segments have also each a like semi-circular band.

For its metamorphosis the caterpillar spins a soft whitish cocoon intermingled with hairs, which is placed between leaves or on the trunks of trees, or in crevices in walls, &c. The pupa is yellowish with the wing parts blackish-brown.

The number of (and the consequent mischief done by) the caterpillars of this species varies greatly in different years. Boisduval, for example, mentions that in 1836 they stripped off all the leaves from the Limes in the garden of the Palais Royal at Paris. They were in such large numbers that they were seen crawling over the ground on all sides. As he observes, the greater number probably died of hunger, because in the following year at the same time only a few individuals were to be seen. Last year appears to have been one of their abundant years, complaints with specimens for determination having been sent us from various quarters.

An effectual but troublesome contrivance has been devised to protect fruit trees from the attacks of another moth, *Cheimatobia brumata* (the Winter Moth), the female of which, like this, if not absolutely apterous, is at least without power of flight, namely, by surrounding the stem with a box or boot with a projecting ledge, the underside of which is kept freshly tarred, so that no insects can creep up it across the belt of tar, and it might be expected that similar means would be equally successful here. But the Winter Moth undergoes its transformation under ground, so that when the female wishes to lay its eggs near the leaves on which its young are to feed, it has to creep up the trunk to get at them, but the Vapourer does not go into the pupa state in the ground, but often among the leaves or on the stem or branches, so that it often has already passed the proposed moat before it requires to deposit its eggs, and the contrivance is thus, as regards it, of comparatively little value. A. M.

## NOTES AND QUESTIONS ON GARDEN DESTROYERS.

**Phylloxera vastatrix.**—This still claims the attention of French chemists and naturalists. M. Barral informs the Académie des Sciences that the Vines are freed from the pest by the use of the following powder: one part of cinabar, five parts of sulphate of lime, eight parts of lime, and eight of flowers of sulphur.

**To Destroy Moles.**—I would advise "E. C." to shoot them. Do not laugh at the suggestion, but try it. I have done it scores of times in my seed beds, when the rascals had got "up to trap." Be out early in the morning with the gun when they are busy rooting, steal quietly to the place (up wind), get the gun almost perpendicular over them—muzzle about a foot or a foot and a half from the ground, consistent with safety—watch until they commence to root, then "blaze away." Dig down afterwards, ten to one the mole is there, as dead as a herring, although he has been six or eight inches below the surface. —*Keppel, in Field.*

## THE FLOWER GARDEN.

### THE GOLDEN THYME.

(*THYMUS CITRIODORUS AUREUS*.)

THIS has no equal in its way in the spring garden; either in lines, patches, or masses it fills the eye with its rich golden colour, while in habit and general character it is all that can be desired. It will doubtless, too, supersede all other Thymes for culinary purposes. It is also the earliest of all Thymes; for, while the common, and silver-tipped, and Lemon-Thymes have hardly started, this golden gem is a dense mass from 4 to 6 inches high. We have a fine row of it on a ribbon border, and even Golden Feather is poor in comparison with it. Beautiful as a summer bedding plant, and proudly holding its own among all the smaller edging plants, such as *Alternantheras*, *Cerastiums*, *Echeverias*, *Sedums*, *Golden Feather*, &c., it is yet more lovely in the spring season. Patches or single plants of it among alpine ferneries will impart a richness to them such as no other plant can give. I intend to grow it by the thousand for contrasting with *Myosotis dissitiflora*, *Aubrietias*, *Violets*, &c. Hitherto there has been a great scarcity of golden contrasts to these blues and purples; the *Doronicums* are too coarse, the *Alyssum saxatile* too late, and the *Golden Feather* too rusty in the early spring. The yellow Pansies and *Violas* are also too late for early spring-work. But this *Golden Thyme* is just the right plant at the right time, and it only remains for us to put it in the right place to fleck or fringe our spring gardens with gold to any extent. It is almost impossible that any plant could exceed this in richness of colouring, compactness of habit, freedom of growth, and hardness of constitution. In regard to the latter it may be said that this winter has not tested it much. This, however, is quite a mistake. The frequent ground-frosts which we have experienced this winter have been more trying to many spring flowers than the much more severe frosts of ordinary winters. *Forget-me-nots*, and even *Violets* (the *Czar* especially) have suffered much; and in regard to Thymes, the common and the *Lemon* alike look rusty, whereas this splendid *Golden Thyme* is strong and vigorous as I have described.

D. T. FISH.

### THE BEST BEDDING PELARGONIUMS.

[FROM among those tried at Chiswick last year we have selected only such kinds as have had \*\*\* attached to them as indicating the highest degree of merit, and which are stated in the "Report" to be equal to first-class certificates. These are arranged in series distinguished first by the leaves, and then by the colours of their flowers, those falling under the respective subdivisions being arranged alphabetically.]

#### PLAIN GREEN-LEAVED.

##### FLOWERS SCARLET.

ELEANOR (Bull).—Pale scarlet; very free and good.

PUNCH (Fraser).—A fine old well-known variety, now superseded by *Warrior*.

WARRIOR (G. Smith).—The best in this class; extra fine scarlet; good and robust habit; large trusses of large flowers, freely produced.

##### FLOWERS CERISE OR ROSEY SCARLET.

LADY MIDDLETON (Taylor).—Bright rose; a good well-known variety; very free-flowering, but bearing seedy trusses.

##### FLOWERS ROSE-PINK.

ADVANCER (Ball).—Bright rosy pink, self-coloured; dwarf and free-blooming.

CHRISTINE.—Pink; small trusses and small flowers, but very free; habit compact; a good old variety.

CHRISTINE SURPASSE (Chaler).—Clear pink; large flowers and moderate trusses; very free-flowering; good grower.

MAIA (Rawson).—New; very bright magenta-pink; small trusses, but very free-flowering. A real acquisition.

Mrs. POTILE (George).—Bright pink, colour of *Cleopatra*; small trusses, freely produced; good; closely resembles *Advancer*.

ROSE QUEEN (Osborn).—Pale pink; top petals white at the base; very free-flowering, but seeds too freely.

#### ZONATE, OR HORSESHOE-LEAVED.

##### FLOWERS SCARLET.

AURORA (Laxton).—Cerise-scarlet, in the same style as *Excellent*, but not so good.

DR. LINDLEY (Bull).—Pale scarlet, with white eye; very free-flowering; good compact habit; a first-rate variety.

FINA (F. and A. Smith).—Good, free-flowering, scarlet; large flowers in fine trusses; habit excellent and free; a desirable variety.

EXCELLENT (Carter and Co.).—Fine cerise-scarlet; good trusses and flowers very freely produced; a really first-class variety.

GEORGE PEABODY (Veitch).—Extra fine bright scarlet; fine trusses and large well-formed flowers, freely produced well up above the foliage; pale-zoned leaf; compact habit; one of the best bedding varieties.

LANDERS (Charlton).—An improved *Vesuvius* in every respect as to growth, habit, and flowering.

REV. J. DIX (R.I.S.).—Bright scarlet; flowers small, but the trusses large; very free-flowering, but soon running to seed; first-rate for early work; good habit.

SAMBO (Downie and Co.).—Intense scarlet; good habit; very free and useful, but superseded by *Mrs. A. Pirie*.

SYDNEY TURNER (Downie & Co.).—Bright scarlet, with pale eye; small truss, but finely formed flower; free and good habit; good of the type.

VESUVIUS (F. & A. Smith).—Scarlet, of one of the best types; grown by all market gardeners round London for cut flowers and as a pot-plant.

WILLIAM UNDERWOOD (Davie).—Pale scarlet, the top petals shaded; free-flowering, and of good habit, but superseded.

##### FLOWERS CERISE OR ROSEY SCARLET.

ALFRED (Pearson).—Bright carmine; good truss and flower; very free habit, and free-flowering; a good variety.

CHARLES DICKENS (Bell & Thorpe).—Bright carmine, with cerise-scarlet edge; very distinct; truss moderate, flowers rather small, but freely produced; habit dwarf; a new and pleasing variety.

CRYSTAL PALACE GEM (Carter & Co.).—Clear rosy cerise; very free flowering, but rather seedy; fine habit, and a first-rate bedder.

FORESTER (Carter & Co.).—Pale rose; good flower, but small truss; very free-flowering; strong grower; a useful shade of colour.

GLORY (Fraser).—Bright cerise; good flower and truss, and very free-flowering; moderate habit; really good.

HERALD OF SPRING (Turner).—Same colour as *Nora*, but not so free; of straggling habit.

IANTHE (W. Paul).—Beautiful rose, shaded with carmine and magenta; quite novel; dwarf habit; flowers good in shape, but the trusses small.

LUCIUS (Bull).—Very bright cerise; a fine flower and good truss; a strong grower and very free bloomer; stands sun, wind, and rain better than any other of the same class; useful and first-class.

NORA (Bull).—Bright rose; large trusses; a very strong grower and free flowerer; good for back rows.

PRINCESS OF WALES (Mews).—Clear rose; very large truss and good flower; dwarf and compact habit; an excellent and first-class variety for bedding or pots.

REGALIA (Turner).—Bright carmine rose of a beautiful shade; flowers large, trusses small, but very freely produced; dwarf and compact habit; a fine variety.

##### FLOWERS ROSE-PINK.

BLUE BELL (W. Paul).—Magenta-pink, very bright, white on the upper petals; good flower and truss; free and good habit; a fine variety.

BEAUTY OF LEE (Foole).—Very bright carmine-rose, white on the top petals; small flowers and truss; exceedingly pretty and compact in habit; pale-zoned foliage.

Mrs. UPTON (Dodds).—Fine bright pink, white on the upper petals; compact and very free-flowering habit; an excellent variety.

PENELOPE (W. Paul).—A little paler than *Forget-me-Not*, with larger flowers and stronger habit; not so good as *Mrs. Upton* for effect.

SURPASSE BEAUFÉ DE SURESNES (Low).—Bright rosy pink without purple, and with white on the top petals; very large flowers, of fine substance, borne on stout footstalks in immense trusses, when grown in pots, but not good for bedding.

##### FLOWERS SALMON-COLOURED OR FLESH-COLOURED.

JEAN VALJEANS (E. G. Henderson).—Bright salmon; good truss and flower; strong grower, and free.

MONS. BARBE.—Salmon shaded; very free and good; a strong grower.

SERAPH (Downie & Co.).—Clear salmon, with white eye; free-flowering; dwarf and compact; quite distinct.

##### FLOWERS LIGHT, WITH DEEP SALMON OR ROSE CENTRE.

AMELINA GRISAU (Salter).—Pure white, with very bright salmon eye, clearly defined; dwarf, compact, free-flowering, and distinct.

ÉUGÉNIE MÉZARD (Salter).—White, shaded with salmon, and deep eye; very free-flowering; dwarf and compact; one of the best.

MADAME WERLÉ (W. Paul).—Pure white, with delicate pink eye; good flower, but small truss; very free-flowering, but not good for bedding; fine in pots, and distinct.

ROSEBUD.—White, with deep salmon eye; very free-flowering, distinct, free and good; dark-zoned foliage; one of the best.

VESPA.—Very similar to the last, but the zone on the leaves not so dark; good.

## FLOWERS WHITE.

MADAME MARTHA VINCENT.—White; tall and free-growing, with good truss of fine flowers; free-blooming; style of White Perfection.

PURTY (Bull).—The purest white; flowers fine, in good trusses; compact and robust-growing; the best of all.

WHITE PERFECTION (J. F. Chater).—Pure white; tall, free-growing and free-flowering; a good useful variety.

## MARBLED ZONATE PELARGONIUMS.

## FLOWERS SCARLET.

SHEEN RIVAL (Kinghorn).—Scarlet; flowers and trusses small; habit strong and robust; very free-flowering, but not good.

## NOSEGAY AND HYBRID NOSEGAY PELARGONIUMS.

## LEAVES PLAIN, FLOWERS SCARLET.

ORANGE NOSEGAY (W. Paul).—Bright orange-scarlet; small truss and flowers; tall slender growth, very free; foliage small and distinct.

VULCAN (Chater).—Crimson-scarlet; good truss and flowers; very free and hardy; strong growth.

## LEAVES ZONATE: FLOWERS CRIMSON AND SCARLET.

BAYARD (Pearson).—Fine crimson; small flowers, but good trusses, very freely produced; good compact habit; a first-class bedder.

CHARLIE CASBON (Casbon).—Brilliant scarlet; a very fine, free, dwarf variety, and a first-class bedder.

COUNTESS OF STRATHMORE (Downie & Co).—Bright scarlet; small trusses, but free-flowering; very pale-zoned leaves; good habit.

CYBSTER (Carter).—Orange-scarlet; strong slender grower, and very free-flowering; a first-rate bedder.

DAVID GARRICK (Bell & Thorpe).—Crimson-scarlet; large flowers in moderate trusses; free-flowering, and of good habit.

DUKE OF DEVONSHIRE (Pearson).—Very bright crimson-scarlet; very large trusses of large well-formed flowers; strong, compact, good habit; very free-flowering. A really grand thing, and fine for pots.

GRAND DUKE (G. Smith).—Vermilion-scarlet, shaded with lake; fine truss and flower, and very free-flowering; moderately compact in habit, good; a fine bedder.

HARRY HIEOVER.—Exceedingly dwarf; pale scarlet; small truss and flower, but very freely produced; a first-rate bedder for front edging.

H. M. STANLEY (George).—Vivid crimson-scarlet; large flowers and very large trusses, produced on long footstalks; good strong compact habit; a new variety, in every way first class.

HON. GATHORNE HARDY (Downie & Co.).—Pale crimson; moderate habit; free-flowering, but sparsely.

KING OF NOSEGAYS.—Fine crimson-scarlet; good trusses; moderately compact in growth, and very free-flowering; good.

LADY CONSTANCE GROSVENOR (Turner).—Fine orange-scarlet; small flowers, but good trusses; very free-flowering; dwarf flat growth; very effective.

LE GRAND (G. Smith).—Soft crimson-scarlet; good flower and truss; very free-flowering; compact good habit; a fine bedder.

LOUIS VEUILLOT (Low).—Crimson-scarlet; very free-flowering; dwarf and good.

MILTON (Pearson).—Crimson, extra large; immense trusses on long footstalks; a good formed flower; a very telling variety; fine for pots, but straggling as a bedder.

MRS. MELLOW (Pearson).—Brilliant crimson, dazzling; good flowers and trusses freely produced; moderate habit; fine for pots; first class.

MRS. VINCENT (Pearson).—Very fine crimson-scarlet; good trusses and flowers; very free and good; pale-zoned foliage.

ROBERT BOWLEY (Downie & Co.).—Bright crimson-scarlet; fine flowers and trusses; very free-flowering; a good habit; a first-class variety.

SOLEIL (Veitch).—Brilliant orange-scarlet; flowers small, but the trusses immense; a strong grower and very free-flowerer; a first-class bedder. The best of its colour for bedding.

STANSTEAD RIVAL (Downie & Co.).—Light crimson shaded with lake; large flowers in small trusses; very free-flowering; dwarf, moderately vigorous habit; a first-rate bedder.

SULTAN (Downie & Co.).—Pale scarlet; large flowers in moderate trusses; dwarf and compact habit.

THOMAS SPEED (Pearson).—Crimson-lake; small flowers, in large trusses; moderately compact habit; free and first-rate.

TRIUMPH DE STELLA (Garaway).—Orange-scarlet; very dwarf habit; good flowers in small trusses; very compact, and very free-flowering; a first-class bedder.

VESPA (W. Paul).—Very brilliant crimson-scarlet; small flowers in good sized trusses; very free compact habit; a really first-class bedder, one of the best, and remarkably effective.

WALTHAM SEEDLING (W. Paul).—Bright crimson; small flowers, but good trusses; very free-flowering; habit long and slender; a fine bedder.

WELLINGTON (W. Paul).—Magnificent, very rich deep crimson shaded; flowers very large, in immense trusses; strong dwarf grower, free-flowering. In Nosegays, the gem of the season.

## FLOWERS CERISE OR ROSEY SCARLET.

AMY HOGG (W. Paul).—Magenta rose; good flowers and trusses; very free-flowering, good habit, and free; a first-rate bedder.

CHILWELL BEAUTY (Pearson).—Magenta rose; moderate habit and free-flowering; a good bedder. Very similar to Amy Hogg.

CLIO.—Magenta-crimson with white eye; fine flowers, and good trusses; compact habit, and very free-flowering. One of the very best for pot culture, and distinct.

INDIAN YELLOW (W. Paul).—Yellowish-sabron, distinct; good flowers in small trusses, but very free-flowering; good habit; a first-class bedding variety.

LADY KIRKLAND (Downie & Co.).—Bright purplish-rose; large flowers in immense trusses; very free-flowering; fine compact strong habit; the best bedder of its colour and class.

LAURENCE HEALWOOD (Pearson).—Bright purplish-rose; large well formed flowers and trusses; a fine showy variety, the habit strong yet compact.

MASTERTICE (G. Smith).—Cerule shaded magenta; large flowers and immense trusses; a strong good grower, and very free-flowering.

VIOLET HILL NOSEGAY (E. G. Henderson).—Lake rose; good flowers in small trusses, but very freely produced; dwarf and compact habit, in every way first-class as a bedder. The model of a bedding variety.

## FLOWERS ROSE PINK.

AMARANTH (Pearson).—Bright rosy-amaranth, quite a new colour; free-flowering; moderate habit; nearly plain foliage.

FLORENCE DURAND (Pearson).—Very bright magenta; large flowers but of little substance; exceedingly free-flowering, and of good habit; a promising variety.

PINK MAY QUEEN (Downie & Co.).—Very bright carmine; good flowers in immense trusses; very free-flowering, and strong compact habit; a first-class variety for bedding purposes or for growing in pots.

WELBECK NOSEGAY (Tillery).—Very bright carmine; very free-flowering; dwarf and compact habit; a good bedder, and very pretty.

## IVY-LEAVED.

## LEAVES GREEN.

WILLSH ROSEUM (Wills).—Bright magenta-rose; very free-flowering; dwarf compact habit; makes a very distinct feature amongst bedding Pelargoniums.

## LEAVES VARIEGATED.

L'ELEGANTE.—White, very large flowers; foliage pale green, edged with white, changing to a beautiful rose in autumn; free trailing habit.

## GOLD AND BRONZE.

BEAUTY OF CALDERDALE (Wimsett).—Pale scarlet flowers, very freely produced; good robust habit; broad dark zone.

BEAUTY OF WOLVERSTONE (Wimsett).—Vivid scarlet flowers; large foliage, of the brightest yellow, narrow dark zone; very effective and distinct; strong, but compact growth.

BLACK DOUGLAS (Downie & Co.).—Salmon flowers, freely produced; a good grower, robust and dwarf; fine dark broad zone, and very narrow yellow edge; first class.

BLACK PRINCE (Carter & Co.).—Good scarlet flowers; large foliage, with broad bold zone; very free-growing; first-rate.

CIBO NULLI (E. G. Henderson).—Pale salmon flowers, with deeper centre; good broad bright zone; robust, yet compact in habit; good.

CLEOPATRA (Carter & Co.).—Flowers scarlet, of good form; bright red broad zone; free and good.

EMPEROR OF BRAZIL (Downie & Co.).—Salmon flowers; a facsimile of Black Douglas, and, if different, not so good.

GOLDFINDER (F. and A. Smith).—Carmine flowers; bright foliage, but washy, pale zone; very compact growth.

GOLDEN SUPERB NOSEGAY (Sampson).—Purple-crimson Nosegay flowers; dwarf spreading habit; a free-grower and free-flowerer; bright yellow foliage, with very pale zone; A. 1.

HIGH ADMIRAL (E. G. Henderson).—Pale scarlet flowers; dark broad zone; a good grower, and first-rate.

JAMES RICHARDS (R. H. S.).—Bright scarlet flowers of good form, very free-flowering; style of Beauty of Calderdale, but neater and more evenly marked; first-class.

KENTISH HERO (Downie & Co.).—Rosy-orange flowers; bright yellow dark-shaded zoned foliage; a good grower; one of the best.

MARÉCHAL M'MAHON (Downie & Co.).—Scarlet flowers; without doubt the very best bronze zonal amongst the new varieties; very dark, broad, and very even zone; flat leaf; good, robust, compact habit; A 1.

MASTER LEONARD (R. H. S.).—Bright scarlet flowers; narrow bright zone; distinct and pretty.

MRS. ELLIOTT (Downie & Co.).—Scarlet flowers; bright reddish maroon zone; good habit and free; first-rate.

PLUTUS (F. & A. Smith).—Bright salmon flowers; foliage lively yellow, with bright red zone; moderate grower, effective.

REINE VICTORIA (Downie & Co.).—Scarlet flowers; very large foliage, yellow ground, with bright broad zone; free; a first-class variety.

REV. W. F. RADCLIFFE (Windebank).—Pale scarlet flowers; very dwarf flat habit; greenish yellow leaves, with narrow dark zone.

SYBIL (F. & A. Smith).—Pale scarlet flowers; very dwarf and compact habit; very bright and broad zone; excellent: one of the best dwarf bedders.

THE MOOR (F. & A. Smith).—Pale scarlet flowers; dwarf and compact habit; good foliage, with broad shaded red zone.

#### VARIEGATED-LEAVED.

SILVER-VARIEGATED; WHITE OR CREAMY MARGIN, NOT ZONATE.

ALBION'S CLIFFS (Chater).—Scarlet flowers; white-variegated; the strongest grower of the section; first-rate for large beds.

ALMA (Turner).—Pale scarlet flowers; good flat creamy foliage; free and good.

BRILLIANT SUPERB (Parsons).—An improved form of the last, with better-defined variegation.

FLOWER OF SPRING (Turner).—Flowers rosy-tinted scarlet; good cream-coloured variegation; free-growing and compact; a first-rate bedder.

MISS KINGSBURY. —Scarlet flowers; perhaps the best white-variegated variety grown for general purposes.

MOUNTAIN OF SNOW (Fraser).—Scarlet flowers; good white variegation; moderate grower and good; habit spreading.

MRS. LENOX (Taylor).—Scarlet flowers; one of the best white-variegated varieties grown.

PRINCESS ALEXANDRA (G. Smith).—Scarlet flowers; white-edged foliage; free-growing; dwarf and compact in habit, very good.

QUEEN OF QUEENS (Bull).—Very bright scarlet flowers; exceedingly free-flowering, the trusses standing well up; large cream-edged foliage; very free, and first-class.

SILVER CHAIN (E. G. Henderson).—Scarlet flowers; cream-margined foliage; free and compact habit; a first-rate variety.

SNOWBIRD (Carter & Co.).—Brilliant scarlet flowers in small trusses; compact and moderate grower, with cream-coloured variegation; very good and distinct.

#### WHITE OR CREAMY MARGIN, WITH RED ZONE.

GLEN-EYRE BEAUTY (E. G. Henderson).—Pale scarlet flowers; moderate grower, free and good; one of the very best; zone very bright.

ITALIA UNITY (E. G. Henderson).—Scarlet flowers, freely produced; a moderate grower in its class, and still ranking amongst the first-class varieties.

#### GOLDEN VARIEGATED; YELLOW MARGIN, NOT ZONATE.

CRYSTAL PALACE GEM.—Carmine flowers, free-blooming; foliage yellow, with green blotch near the base; a free compact grower; one of the best bedders.

GOLDEN CHAIN (Scott).—An old favourite; foliage clear green, with broad margin of golden yellow; very bright; a slow grower, but still unsurpassed in its way.

GOLDEN FLEECE (Scott).—Bright scarlet flowers; foliage large, very bright yellow, with small blotch of green on the lower part; a very dwarf and compact grower.

#### YELLOW MARGIN WITH RED ZONE.

AMY RICHARDS (R. H. S.).—Scarlet flowers; good flat foliage with fine bright red zone; a good grower, free and first-rate; one of the very best.

LADY CULLUM (E. G. Henderson).—Scarlet flowers; a variety always good and effective, whether bedded out or in pots; zone broad, dark, on a flat leaf; a good grower; first-class.

LOUISA SMITH (F. and A. Smith).—Scarlet flowers; foliage very round, with narrow bright zone; free-growing, of good habit, and distinct.

MACBETH (Bell & Thorpe).—Decidedly the gem of the season in

tricolors; a strong robust grower; large flat foliage, with a very dark broad zone; altogether a grand thing.

MRS. POLLOCK.—Still an old favourite amongst the free-growing bright-coloured tricolors; always effective.

MRS. TURNER (Turner).—Scarlet flowers; foliage flat, the centre small, the zone broad and brightly coloured; free-growing, compact, and good; distinct and worthy a place.

QUEEN VICTORIA (Perkins).—Pale scarlet flowers; broad leaf, with broad dark zone; a good grower and distinct.

SIR ROBERT NAPER (Carter & Co.).—Flowers flesh colour; very dark and very broad zone, shaded with bright red; a first-rate distinct variety.

SUNSER (E. G. Henderson).—Distinct and pleasing foliage, but of very bad habit and constitution.

#### YELLOW SELF-COLOURED.

CREED'S SEEDLING (Creed).—Crimson; good flowers in small trusses, well up, and very freely produced; the foliage bright greenish-yellow; very free and compact habit; A 1.

GOLDEN SUPERB NOSEGAY (Sampson).—This variety appears from a distance to come in this class, but upon closer examination is found to be zoned.

JASON (W. Paul).—Scarlet flowers, but not very free-flowering; foliage bright soft yellow; dwarf, compact, and first-rate.

*Thos. Moore, in Proceedings of the Royal Horticultural Society.*

#### SPRING GARDENING AT BELVOIR CASTLE.

WHILE cold winds and driving snowstorms plainly indicated that we had scarcely escaped from the thralldom of winter, it appeared something more than tautalising to hear spring flower gardens described as masses of beauty; but at Belvoir, on the 17th of April, this was really the case. On approaching the grounds the noble castle of Belvoir arrests attention, on account of its commanding position, and also on account of its massive yet beautifully broken outline, thrown into bold relief by the sky background; in fact, its position is everything that a castle of such formidable dimensions and nobility of contour should have—a position doubtless equally appreciated by its ancient occupants when they bade defiance to their foes, and by the modern sight-seer who wanders thither in quest of the picturesque.

No special dispensation of climate seems vouchsafed to this particular locality; the road-side flowers are but Daisies—no banks of Ground Ivy or Speedwell to show that spring had roused her sleeping children even a week earlier than in Yorkshire; but it must be borne in mind that I am yet on the north side of the hills. I ought to have mentioned before that on each side of the castle knoll a range of hills trending south-west is covered with a dense wood of fine old timber, with a beautifully broken outline in the foreground, this wood rising in height a little above the base of the castle walls; and that on the north-east side there is a similar furnishing, only of much less extent, owing to the rapid declivity of the hills in that direction. Making one's way to the garden, which is situate on the south side, we pass in close proximity to the castle, where we have an uninterrupted view of it from the road. There it stands, combining the massive outline of the olden time with all the perfection of modern stonework; if it lacks the poetic halo of ruin and decay, it evidently makes amends for the deficiency by possessing all the necessaries for palatial life of modern times. The grassy slope up which we now look is broken into easy terraces, not sharp, angular formalities—these would be quite out of place—no long flights of steps, but quiet rounded lines, that sweep as it were from side to side, thus rendering the ascent for the pedestrian gradual and easy, but, from our point of view, showing no sign of a walk whatever. Descending some distance downhill, we reach the gardens, a peep at which, almost a square of some eight acres in extent, within the walls, and a run through the houses, was soon accomplished. But let us pass on to the primary object of my visit—the spring gardens. Our walk for about half a mile was through woods skirting the south side of the castle, which have undergone a good deal of thinning, the coarser undergrowth making way for such shrubs as are adapted for such semi-shaded localities. As we pass along one element of floral beauty crops up in the shape of large masses of *Eranthis hyemalis*, which, when in bloom, must have been lovely, and even now their dark green foliage

and dense growth make a pleasing contrast with the lighter tints of the Grass; that, however, is a bit of nature's own flower gardening. So we proceed, until presently, in the distance far below us, we get a peep of a few irregular groups of flowers, almost shut out from view by intervening shrubs, and another hundred yards brought us to a delightfully secluded open space, shut in on all sides, except the sunny south, by masses of shrubbery. Here the walk, which hitherto followed in graceful curves the natural line of the hillside, wandered through groups of beds of various sizes and patterns, now bending one way, now another, as though it wanted to make the most of the little paradise into which it had led us.

Here, then, I am in the original spring flower garden, where the first happy attempt at Belvoir was made to blend the springtide of nature and art together; and how am I to describe it? Here of a truth I am at a loss; there is a beauty and charm about it that words cannot convey. Besides the

they were interspersed. What can be happier than the idea of associating the blue wood Anemone with a golden carpet of Stonecrop? or lighting up, as it were, the lovely crimson Erica carnea with such golden surroundings? On this, and on the judicious way in which Mr. Ingram carries out such arrangements hinges in no small degree the strong spice of nature which is the charm of these spring-flower beds.

Many imagine that spring gardening must necessarily consist of early-flowering bulbs, which, to my mind, have never proved satisfactory. In the first place, there is a lack of foliage with many of them—then, again, there is a uniformity and sameness; and how short-lived is their maximum of beauty! Crocuses may be lovely for a few sunny days in March, but let the sun decline to beam forth, and their loveliness is hid, and soon their glory is departed. Squills are more lasting, and so are Hyacinths and Tulips; but here, in these beds, we find all these, not rising from a surface of naked earth, but

Belvoir (from a Sketch by Mrs. Ingram).

sheltered character I have just alluded to, the natural lie of the ground is to the south, the surface diversified in a somewhat irregular manner—here a flat space, with a group of beds somewhat geometric in character; there a slight elevation crowned with a bed of irregular outline; or if, as in some cases, formal, then irregularity and diversity was given to it by the arrangement of the flowers. Here I must mention one all-important point; not a bit of soil was visible in the beds—no stiff formal cut margins and 6 inches of mother earth, to show that art had got the whip-hand of nature, were to be seen. The flowers themselves, with loving affection, hugged, as it were, the emerald sward. But how was the soil disguised? In some cases by thick planting, in others by covering its surface with the golden and glaucous forms of Stonecrop, and with various mossy and crustaceous Saxifrages; these, while answering the purpose of garnishings as it were, assisted materially in bringing out the beauty of colour in flowers amongst which

from banks of Violets—the giant Czar with its dark blue flowers, or the Neapolitan with its more delicate tint, breathing a fragrance such as they alone can yield. Interspersed among them are fine tufts of the common yellow Primrose, intermixed here and there with the double Lavender and the white, the whole margined round with the Aubrietia, in many fine forms, such as Mr. Ingram has been enabled to obtain by a careful process of seeding and selecting. The effect of such an arrangement is grand in the extreme, and, as a crowning element, there is a sort of aerial addenda, rising 9 or 10 inches above the general surface of the bed, in the form of rich, bright, rosy Tulips, whose single blooms yet unfolded, borne upon slender, almost invisible stalks, arranged about 15 inches apart, gave a charm to the effect such as must be seen to be appreciated.

Take, again, another irregularly shaped bed, with glorious tufts of the old Saxifraga crassifolia or cordifolia, their massive leaves, almost semi-tropical, harmonising with their equally

massive trusses of soft pink blossom; bordering these and following out the irregular line is the *Heuchera glabra*, whose dark deep chocolate foliage contrasted well with golden *Feverfew*, between which again arose tufts of the common *Anemone* in its varied tints of blue, scarlet, and crimson, beaming in full expanded beauty. Then came a row of *Polyanthus*, of which Mr. Ingram possesses a splendid strain, some of them assuming the type of the *Oxlip*, only larger, and of a deep colour almost approaching to orange. Here you have no lack of variety. Outside of these came the old *Arabis albidia*, which, like the *Aubrietia*, has improved under constant selection, acquiring compactness of growth and abundance of bloom, with a waxy substance of petal such as I have not seen before. Outside of all came the purple-leaved *Bugloss*, rising from a golden bed of *Stoncrop*. Here and there dotted over the surface were *Hyacinths* of a lovely magenta colour, which, protected by the foliage of the plants, rose well up above them, and gave an effect somewhat similar to the *Tulips* before described, but not so aerial. These descriptions doubtless indicate that a certain amount of formality is evident in the beds thus described; but, nevertheless, they do not strike the eye as formal. One bed in a secluded nook contained fine tufts of *Christmas Roses*, the beauty of which was, however, all but past. Amongst them I noticed, besides the old *Christmas Rose* and its larger varieties, *H. olympicus*, *H. orientalis*, *H. colchicus*, *H. atropurpureus*, and *H. atropurpureus*; these were located together, being looked upon as fixtures. The same applies to the *Hepaticas*, which ought to form a marginal line round the group, the various colours alternating, as they do not flourish under the influence of repeated removals; and they would appreciate a permanent tenancy under their big relations. The *Dog's-tooth Violet* surrounding the margin of one bed, though out of bloom, had left in its mottled leaves a legacy which for beauty was not to be despised; *Lamium maculatum* was also largely used with excellent effect. *Omphalodes verna*, beside whose beauty even *Myosotis dissitiflora* must "pale its ineffectual fire," was well represented. In some of the little pin-cushion beds, covered with the crustacean *Saxifrages*, and where the major form of *S. oppositifolia* would look charmingly, I noticed beautiful tufts of the rarely-seen *Polygala Chamæbuxus* covered with bloom; this is largely grown, and used for spring purposes. Both *Erica herbacea* and its far finer and more compact variety *carnea*, as also the white form of the Mediterranean *Heath*, grown as they are here in compact tufts and well bloomed, have a wonderfully fine effect. The old wood *Anemone* in its double and rosy form, and also *A. ranunculoides*, *apennina*, and *blanda*, are all amenable to cultivation under the favourable circumstances just described. These, and many others I have named, when planted in a terrace garden, usually look the picture of misery—in fact, the formal, exposed flower garden we usually find adjacent to the mansion is not the place for spring gardening. Here, secluded and sheltered by trees and shrubs, the spring flowers are unmistakably at home.

Before bidding adieu to the beauties of the original spring garden, I was somewhat surprised to find that its situation is within a stone's throw of the outworks of the old castle, as by passing through a thicket of shrubbery I found myself face to face with a set of bronze guns, pointing from the casemates of a plateau raised some 10 feet above the level of the Grass sward; the exterior of the plateau being also a level of Grass, unbroken by shrub or other adjunct, adding to the repose and nobility of the majestic pile of building. Nor did I really appreciate the charm of the flower garden to its full extent till my return, with the mind freshly imbued with the austere severity of the old castle. But a few yards of secluded walk, and the whole scene breaks on view—a charming kaleidoscopic picture, widening from a somewhat narrow embouchure, and embracing a tolerably extensive mass of the topmost twigs of the trees planted far below, rich with those indescribable purple tints that all plantations present when the first flush of sap rises responsive to returning spring. On reaching the edge of the plateau to descend, far below is another group of beds, smaller in extent, but from this bird's-eye point of view exquisitely charming. These were the beds that first attracted my attention in the distance; and descending by a wild path, partly steps and partly sloping walks, we reached the low level. By the way, I ought to have mentioned in the upper

garden a raised bed of the beautiful rosy *Rhododendron præcox*, which had just passed its best with the exception of one plant; this was in perfection—evidently a distinct form, deeper in colour, more compact, and later in blooming than the ordinary *R. præcox*, and a variety well worthy of a name and a place in every spring garden.

Passing along in a south-western direction, we take the walk known by the name of the Duke's Walk; this skirts along the slope about half-way up. After walking a short distance, the clearance of the valley beneath—which was, up to a recent period, one mass of trees—has been considerable, and presents a magnificent site for a flower garden. A noble group of *Birches*, the most graceful of all trees, with their beautiful silvery stems, stand out objects for admiration at all times, but perhaps never more lovely than when their branches are festooned and pendent with catkins, giving just a sufficient amount of massiveness to their graceful outlines. These have all been preserved; and when, as will doubtless be the case at some future time, this extensive portion of the valley is broken up into an irregular surface round the margin, and groups of *Rhododendrons* are established on the knolls, fringed with *Heaths* and other dwarf American plants, contrasting with the smooth Grass surface, and enlivened here and there during summer with the bright denizens of the flower garden, we shall have all the elements of the beautiful on a grand and extensive scale. On the right-hand side the rising ground is as wild as Nature herself has formed it; but after some ten minutes' walk, we are admonished by a gate and a wire fence that we are about to enter some sacred enclosure. Scarcely have we passed the unpretending little entrance before we are made aware, by the presence of some goodly old *Conifers* and other trees and shrubs, which must have been established here at least fifty years ago, that we are in what is known as the Duchess's Garden. Prominent above all others here is an *Araucaria imbricata* fully 40 feet high, and beside it *A. Cunninghami*. In a situation, therefore, where *Cunningham's Araucaria* has withstood the vicissitudes of our climate for years, there must be some exceptionally favourable influences. Here, however, we must pause and look above and below. Above, as the eye ranges up the face of a wild bank some 50 feet high, jut out irregularly masses of rock; presenting the appearance of an old quarry, but covered with vernal beauty. Below, the surface of the ground is still wilder and more irregular; every here and there, where a little natural plateau has presented itself, it has been used for a few beds, filled to overflowing with blooming beauty. These beds, irregular in outline, appeared, as viewed from above, to indicate that the wildness of Nature herself was so lovely that Art dared with but trembling hand to poach on her royal preserves; but this is only in appearance, for I shall have now to show that Art and Nature have here been so happily blended together as to defy anyone to detect where the one ends and the other begins. Our path terminates in a fine old summer-house, notable for its ecclesiastically Gothic rustic character; windows in whose tracery the old Oak branches twist and twine in all sorts of wild vagaries; its thatched roof almost hidden beneath the drooping sprays of the *Canada Spruce*—a tree that, for light graceful elegance, bears the same relation to evergreens as does the *Birch* to deciduous trees, but more capricious in its tastes as regards soil and locality, and but rarely met with.

Let us now digress from the path, and, climbing upward, let us examine in detail the materials which cushion these projecting rocks with floral beauty. Our path now has lost its formal outline; it more resembles stepping-stones, between the interstices of which a stream of flowers is in continuous flow—here quietly gliding past some projecting stone in the form of a mass of the glorious vernal *Omphalodes*, studded with flowers of an azure blue, the brightness of which raises even a pinky blush on the adjacent *Forget-me-Not*; there tumbling in a mimic foam-like torrent over a rocky ledge is a mass of pure white *Arabis*, intermixed with the purple *Aubrietia*, hanging far down in graceful irregularity. But these beauties, however effective and lovely they may be, constitute, as it were, only the frame or setting of the picture. So wild and natural is the arrangement that one can hardly imagine it to be artificial. As we climb upwards we find spaces to the right

and to the left—say two or three square yards in extent—with a nearly level surface, each filled with soil specially prepared to suit the plants they are intended for. Here we have a group of the diminutive Saxifrages nestling affectionately round their queenly representative, *S. longifolia*—there we have a mass of the rarer forms of *Stoncrop*s; a similar space is devoted to the silvery *Senecios*—*argenteus*, *incanus*, and *uniflorus*; another to *Silenes*, with their pink and snow-white flowers peeping out of emerald cushions. Higher we reach a moderate extent of level ground, well prepared with bog and leaf soil; and here we have a group of *Epimediums*, from the midst of whose light green leaves, suffused in their younger state with that lovely pink tinge that gives such a charm to some of the Maiden-hair Ferns, arose the sulphur-yellow blossoms of *E. pinnatum elegans* by thousands, intermixed in wild profusion with the large white blooms of *E. macranthum* and various other species, growing with a luxuriance that could not be suppressed. This was alone a sight worth travelling miles to see. Similar localities are devoted to *Trilliums* and *Cypripediums*, and various other partial-shade-loving plants. Every here and there are nooks with a nice background of shrubs, containing rustic seats. Reaching the top, we follow a walk to a seat beneath a noble old tree, and, looking around from this elevated spot we catch a glimpse of the *Abies canadensis* already alluded to, with its graceful spray-like growth; beyond it a noble Portugal Laurel, with a well-formed stem some 2 feet in diameter, comes into view, and down the irregular slope beyond the walk leading to the summer-house are planted in prominent groups the mountain Bamboos, full of life and vigour to the very tips of their last year's stems, and some noble specimens of *Arundo conspicua*, fully 10 feet across, so distinct in their habit of growth as to be well worthy of association with the Pampas Grass and other plants of that character. This *Arundo* reminds one of a giant *Renealmia* rather than a Grass. Intermixed among these prominent irregularities were the spring-flower beds to which I have already alluded; and down in the valley far below we get a glimpse of the group of Birch trees, and of that open expanded glade, at present bare, but which in summer is a wilderness of wild Bracken. Beyond the summer-house, beneath the shade of giant overhanging trees, a space has been recently dedicated to Ferns; and here, beside our British Ferns, doubtless many of the semi-hardy sorts from New Zealand, Japan, North America, and Mexico will find a fitting home. Through a portion of this rockery Mr. Ingram intends some day to have a continuous stream of water, and with the addition of an artificial cave or two, the filmy Ferns will here find a fitting home; and possibly even the lovely *Todea superba*, of which I saw a number of fine plants in one of the houses, may be found under such favourable circumstances capable of withstanding the rigour of our climate.

Amongst the many usually tender shrubs planted out here, I noticed some fine plants of *Camellias*, studded with hundreds of buds, looking models of health and vigour, also some of the Sikkim *Rhododendrons*; and I have no doubt that the Chilean *Lapageria* would also thrive well, and have a glorious effect, festooning some of the old tree stumps that yet remain, and contribute not a little to the general grace and beauty of the scene. One word as to the mode in which the rockery has been made in the Duchess's Garden. The materials all belong to the locality, and consist of a slightly reddish marl stone, with horizontal fractures. In the disposal of these stones Nature's arrangement has been followed; they jut out here and there on their natural bed, sometimes singly, sometimes one on the top of another, the crevices between forming admirable root-hold for the plants. We have no attempt at impossible pinnacles, or aiming at effects that the materials do not justify. Mr. Ingram's knowledge of geology is such as to guarantee that no infringement of Nature's laws would be admitted.

*Botanic Gardens, Hull.*

J. C. NIVEN.

*Aster scorzonerifolius*.—A new species introduced by M. Roczel, from the Sierra Nevada of California, resembling *A. alpinus* in habit, but differing from all other known species in its radical leaves. These are very long, ribbon like, smooth, entire, channelled, usually 5-ribbed, erect or nearly so, and longer than the stem, which is simple and about 10 inches high. Stem-leaves sessile, linear-lance-shaped. Flowers terminal, solitary (seldom axillary), large, of a pale violet colour with yellow disk. The plant is quite hardy.

## NEW ROSES.

Of the new Roses that have already been shown this season, I must give the palm to Hybrid Perpetual Star of Waltham, a seedling raised by Mr. William Paul, of Waltham Cross. This is a very fine pale bright red coloured flower, very full, with great depth of petal, and an abundance of them in it; habit vigorous and free. As seen at one of the recent meetings of the Royal Botanic Society, this flower was as near perfection as a Rose could well be. Hybrid Perpetual Mons. Claude Levet is also remarkably fine; colour shaded rose, flushed with violet; large and full, and with a good free habit. Hybrid Perpetual Madame Jamin is another splendid flower, and its beautiful pale blush pink tint will be certain to render it acceptable to everybody. If the testimony of our leading rosarians be of any value, this will prove to be one of the best of the new Roses just being put in commerce. A thorough good Rose is Hybrid Perpetual Etienne Levet, and this so completely established its character as a good autumnal flower that its general good qualities may be taken for granted. This is of a shaded brilliant rose hue, flushed with violet; the habit appears to be all that could be desired. Tea Madame Cecille Berthod is a beautiful bright pale yellow flower, of remarkably fine build and substance, and a free grower; it is a variety showing the possession of a great deal of refinement. Tea Madame Camille has full and finely cupped smooth flowers, with a great depth of petal; the colour blush on the exterior, with a bright salmon buff centre. Tea Madame Jules Margottin is a charming Tea Rose, the circumference of the flower flesh white; the centre primrose and nankeen; in the bud state it is simply perfection; the habit is vigorous and free, and it has a most desirable upright growth. Qu.

## SPRING-FLOWERING CLEMATISES.

At a meeting of the Royal Horticultural Society, on April 16, a group of new spring-blooming Clematises was staged by Messrs. Jackman, of Woking. There were seven finely grown and flowered plants, trained over oval wire frames, that were studded with large eight-petalled flowers of varying tints. Of these, four were deemed worthy of first-class certificates, viz: Fair Rosamond, silken white, tinted on the edges with pale soft mauve, and having purple stamens, flowers large in size, stout, well formed, and distinct; Stella, pale violet, paling off to lilac on the edges of the petals, and with a flame of pale puce along each, flowers large and of fine quality; The Queen, very pale mauve, with a slight pale green flame along each segment, large and very fine; and Vesta, pure white, with a fine primrose-green stripe along each petal, a beautiful white Clematis. The others were scarcely less inferior in size and beauty, and comprised Lady Stratford de Redcliffe, pale shining mauve, with a creamy flame along each petal, flowers of fine form, and vigorous habit. This variety will in all probability prove the precursor of a new race, as it has resulted from a cross between the spring-flowering *C. Standishii* and the summer-flowering *C. Jackmanii*, the principal change being in the habit, which is much freer and denser in growth than is usually seen in this section. There were also Maiden's Blush, pure white, with a flame of primrose-green on each segment, dark stamens, very fine; and Lord Derby, pale silken mauve, with a dash of cream along the centre of the petals, very delicate and fine. These will form valuable additions to this beautiful class of spring-blooming plants, many of which could be bloomed in the open air if planted in warm, sheltered, and sunny spots, and in large domains. It may also be stated that Messrs. Standish & Co., of Ascot, have raised a beautiful lot of seedlings from *C. Standishii* fertilised by other spring-flowering types. In many of these can be found what is much to be desired—flowers having a deeper hue of colour than is present in *C. Standishii*. We are now rich in white and pale flowers, also in those having most acceptable delicate touches of mauve. Tints of mauve deepening to violet, and again to blue and purple, are needed, and these Messrs. Standish bid fair to supply. They have a large number of selected seedling varieties that are full of promise. Any house in which these Clematises can be screened from the frost is a fitting place in which to grow them. It must not be supposed that an elaborate conservatory or greenhouse, furnished with a costly heating apparatus, is absolutely essential; such facilities as these would assist the development of the beauty of the plants, but are not essential. Liberal culture is essential, nay, indispensable. Whoever grows them in pots should use a rich soil in the first instance, and when blooming time comes there must be a liberal mulching with manure and occasional supplies of manure water. These assist the development of flowers having a

fine texture and exquisite tints; and when such qualities as these are present, then the spring-blooming Clematis is seen to the best advantage.

R. D.

### OLD-FASHIONED WALLFLOWERS.

AMONGST Wallflowers for ordinary purposes, nothing equals the sort grown in the market gardens round London. Great care is taken every year to select the darkest-coloured and earliest-flowered kinds from amongst the immense quantities which are grown, and to mark them, by inserting a peg alongside of such sorts as are selected for seed. The seeds are sown the following spring, as early as the weather permits, March being the common time, but if in February, so much the better. As soon as the plants are strong enough, they are transplanted to spaces under trees and between rows of fruit bushes, in lines a foot apart, and here they are allowed to remain. They grow pretty well in such a position, and in moderately open weather they come into bloom about Christmas, and sometimes earlier, and continue to flower well until May, and, if the weather be not too dry, well into June, when they are supplanted by hosts of other flowers. The plants are never preserved for more than the one season, as young ones are always the best. The continued selection of the finest and earliest kinds for seed has a material influence upon their time of flowering—a circumstance which I have fully proved. Last year I procured some much-applauded sorts from various sources, and in March I sowed them, together with some of my own old-fashioned market strain (I may say old-fashioned, for during my experience of twenty-seven years, I never grew any but the one kind, which was old-fashioned when I started), all on the same piece of ground, but each kind in separate patches. I transplanted them all under the same conditions, with the following result, viz.:—My own seedlings came into bloom in the last week of December, and have flowered well since, and with the exception of a bloom here and there amongst the others, it was more than mid-March ere they came into flower, my own old strain producing the most and best-formed flowers, and the darkest-coloured ones, with not more than half-a-dozen yellow-tinged flowers and not one striped one amongst them; whilst amongst the others one-third of the plants yielded yellow and crimson-striped or yellow blotched varieties, which, in the market, would not realise nearly the price of my own old-fashioned market-garden kind; consequently I must discard the new comers, and still retain my old and valuable strain.

A MIDDLESEX MARKET GARDENER.

**Ramondia pyrenaica.**—With reference to Mr. Palmer's inquiry (see p. 331), I beg to state that I have grown this plant in various situations, and have never found the least difficulty in its culture, except that it is impatient of excessive drought, and, under a hot sun, is liable to turn brown and lose its foliage, which weakens the plant for the succeeding year. It is doing fairly with me in an open rock border, composed of broken stones mixed with equal parts of sand, loam, and peat, and blooms freely in this situation, but as the flowers are very fugitive, its beauty soon passes away. In a cold frame it is one of the easiest alpine to grow. It likes thorough drainage and a cool moist situation. I repot it every year at midsummer and put about seven roots in a 12-inch pan. The soil I use consists of equal parts of loam and sharp sand, with a little peat or leaf-mould. I place the pans in the shady part of a deep pit; they are now quite covered with healthy rosettes of the handsome rough leaves, and in about six weeks will be adorned with a profusion of delicate mauve flowers. To preserve its beauty unimpaired it is necessary to keep the flowers from exposure to the sun, and also to avoid wetting them in watering. The flowering pans of *Ramondia* will be lovely objects for at least three weeks, and well worthy of a place in the conservatory or sitting room.—GEO. MAW, F.L.S., *Bentham Hall*.

**Calandrinia umbellata.**—For vivid beauty and brilliancy of colour there is nothing to equal this in cultivation. It is as cheap as the Wallflower if raised from seed; and moreover may be grown to perfection by the treatment which suits bedding plants—a treatment with which every person fond of gardening is now familiar. Its colour is a vivid magenta, open in the full sun to an almost inconceivable glow, yet soft and refined. In the evenings and in cloudy weather it shuts up, and nothing is then seen but the tips of the buds. It grows about 3 inches high, and does very well in any fine, sandy, peaty, or other open earth. It may be sown now or in spring, or indeed at almost any season that the seed comes to hand. It is a hardy perennial on dry soils and on well-drained rockwork, but for the bedding garden it is far best when raised every year from seed, kept over the winter in frames, and turned out the beginning of May in a free-growing condition. It looks best in small beds, but may be used with advantage as a broad edging to large ones. The *Calandrinia* may be sown in autumn with advantage, half the seed

being kept for sowing early in spring. It should be raised on a gentle hot-bed to compensate for sowing so late, and is best kept in a snug frame or pit with warm aspect for the winter. In spring, very early, some seed may be sown in a Melon or Cucumber frame, or other warm structure, and brought on as fast as things may be at that season. I have seen it do beautifully in fissures of rockwork, and even remarkably well when sown in large beds in the open air in a nursery.—F.

**Rocky Knolls.**—In THE GARDEN (p. 331) a rocky knoll in Osmaston Gardens is cleverly sketched, and the description rightly sets forth the pleasure that may be derived from the introduction of such little bits of scenery to our gardens when laid out and planted with taste. My object in thus writing is to state that I lately observed another rocky knoll in a pleasure ground in this neighbourhood, which struck me as deserving of notice. This was in the shape of a well-designed piece of rockwork of about 14 feet in height, and the same in breadth, planted with *Berberis Aquifolium*. The creeping roots of this *Berberis* had struck all through the mass of stones, producing quite a mass of fine green foliage; and, being in flower at the time, the whole looked, at a distance, like an immense plant. In some of the crevices where the *Berberis* had not spread, little patches of the *Aubrietias* were seen in full flower; and at the base of the knoll, in places on the Grass, the white-flowering *Arabis* presented itself in masses, as well as *Primroses* of different colours. This was seen in the shrubbery at the end of a walk, to which it formed a fitting and tasteful termination.—WILLIAM TILLERY, *Ivelbeck*.

**Coloured Primroses.**—This place has always been noted for its wild flowers, but more especially for its coloured Primroses, which this season have been truly lovely. I have been here seven seasons, but have never seen them so gorgeous before. Last summer suited them well, as they delight in shade and moisture, and the rains brought into existence a whole host of seedlings, which have flowered, though many of them are small plants furnished with not more than six leaves. I observe that there is a great improvement every spring in the fresh seedlings, both as regards colour and form; but this season there is more than an average quantity of the flowers first-rate. They are growing in a shrubbery not far from the garden, where they have received no attention: therefore the improvement in colour and form has been entirely effected by means of insect agency.—W. ALLAN, *Guntton Park*. [Along with this communication came a boxful of Primroses, all beautiful. In colour they ranged from delicate pink to brilliant mauve, and when seen *en masse* must be very effective.]

**Oxalis corniculata rubra.**—This is an exceedingly beautiful plant, forming patches of deep bronzy-red leaves, studded with golden stars. I do not know whether any use is made of it in an artistic point of view, as a carpeting plant. I once had a small round bed of it, edged with a silvery Saxifrage, and dotted over with *Echeveria glauca*, the effect of which was charming; but such is the astonishing fecundity of this plant, that I bitterly repent ever introducing it into the garden. Every part of my garden is now covered with it, even the gravel road and the walks. Every pot on every shelf in my little greenhouse swarms with it, and I fancy I can see some bits of it on the top of my house. Much against my inclination, I destroyed last summer thousands of this beautiful plant. Still it may have its proper place. Old quarries and rough rocky places, especially in a calcareous district, would suit it well, and their bareness might with advantage be hidden by a handsome plant which speedily covers the most unpromising surfaces.—THOS. WILLIAMS.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Tasmania aromatica.**—This interesting plant, usually grown in the greenhouse, has withstood the past winter at Bilton.

**Solomon's Seal.**—What a pity it is that the stately grace of this lovely plant is not often visible along shady walks and in the fringes of shrubberies in our gardens. It is one of the many plants that have been destroyed, to a great extent, by the mischievous system of digging every surface, which is so common in our gardens.—H.

**Erodium guttatum.**—This is one of the handsomest of the small-flowered species, and grows abundantly throughout Algeria from the southern borders of the Tell, at Bonghari, to the Sahara, south of L'Aghout, where it forms neat perennial tufts of glaucous leaves, covered with a profusion of rosy-lilac flowers with a dark purple centre, as big as a shilling.—G. MAW, *Bentham Hall*.

**The Creeping Forget-me-Not (*Omphalodes verna*).**—I find this to be the easiest of all plants to naturalise, and it is so pretty blooming throughout the spring months. I once thought it required moist free soils to become naturalised in, but find this is not so. Although it thrives best in a cool elevated region, it runs about freely in any wood or copse or shrubbery, in any part of the country.—W.

**Idiotic Gardening.**—I have been pained to see in this garden land of Kent many wretched examples of what are called "polychromatic beds." The hateful colours of their broken bricks, &c., are mingled with the delicate tints of spring and early summer flowers. The wretched example of Kensington has caused many to fancy they are gardening, when they are wasting precious time and energy by breaking up and carefully spreading forth in geometrical pattern broken bricks, &c., to produce ridiculous eyesores.—R.

## THE GARDEN IN THE HOUSE.

### BEGONIA SEDENI.

BEGONIAS, as a rule, are amongst the finest of indoor flowering plants, and a large section of them is also remarkable for the beauty of their foliage. *B. Sedeni* is a garden hybrid, and, as regards flowers, one of the handsomest of the genus. Its blooms are individually large, of a bright magenta colour, and are produced in the greatest possible profusion. The leaves,

dormant during the winter, either in the pot in which it has been growing, or in sand, like *Achimenes* roots. In February or March it should be started, using well-drained pots containing a compost of loam, peat, and thoroughly decayed manure, mixed with some sharp river or silver sand. Small pots should be used at first, and the plants should be shifted as they advance in growth into larger ones, or they may be potted at once into 6-inch pots. If large specimens, however, are desired, they should be potted regularly, and when in sufficiently large pots they should be supplied occasionally with

*Begonia Sedeni.*

which are also large, are of a shining dark green colour, with veins more or less tinged with red. In order to develop the full beauty of this *Begonia*, a little more heat than that of an ordinary greenhouse should be given when it is starting into growth, but afterwards it may with advantage be removed to a warm position in any ordinary greenhouse or conservatory. In autumn, when the plants show signs of decay, they should be kept rather dry, until after a week or two the stems may be cut off close to the soil, and the roots kept dry. As it is a tuberous-rooted kind it must be allowed to remain

manure water. For indoor decoration, for which this *Begonia* may be made useful, 6-inch pots are sufficiently large, and in these excellent plants of it may be grown. It has flowered beautifully with Messrs. Veitch, of Chelsea. J. W.

---

**Novel Mode of Dishing Strawberries.**—Procure a round dessert dish, and surround it with a tin rim 1 inch deep, filled with peat and sand. Then place on the surface small round stones of the size of pheasants' eggs, and plant between them *Selaginella apoda*, keeping it in the shade until the stones are half covered, then remove the stones and put in their place ripe Strawberries, which will make a dish fit for an emperor.—R. GILBERT.

## THE KITCHEN GARDEN.

### ASPARAGUS.

(Continued from p. 365.)

#### ASPARAGUS CULTURE IN FRANCE.

ASPARAGUS is grown much more extensively and to a much larger size in France than it is in England. The country is almost covered with it in some places near Paris; small and large farmers grow it abundantly, cottagers grow it—everybody grows it, and everybody eats it. The system of culture is so essentially different from ours, and so successful, that it is desirable to make it fully known. Near Paris it is chiefly grown in the valley of Montmorency and at Argenteuil, and it is cultivated extensively for market in many other places. About Argenteuil 3,000 persons are employed in the culture of Asparagus. It is grown to a large extent among the Vines. The Vine, under field culture, is simply cut down to near the old stool every year, and allowed to make a few growths, which are tied erect to a stake; they do not overtop the Asparagus in any way, but on the other hand the strong plants of that show well above the Vines. It is not in distinct close lines among the Vines, but widely and irregularly planted. They simply put one plant in each open spot, and give it every chance of forming a capital specimen, and this it generally does. When the stems get large and a little top-heavy in early summer, a string is put round all, so as to hold them slightly together (the careful cultivator uses a stake), and the mutual support thus given prevents the plant from being hurt by wind in its prime. We all know how apt it is to be twisted off at the collar by strong winds, especially in wet weather, when the drops on every tiny leaf make the foliage heavy. The growing of Asparagus among the Vines is a very usual mode, and a vast space is thus covered with it about here. But it is grown in other and more special ways, though not one like our way of growing it, which is decidedly much inferior to the French method.

Perhaps the simplest method, and the most worthy of adoption, is to grow it in shallow trenches. I have seen extensive plantings that looked much as a Celery ground does

Common French mode of forming an Asparagus plantation.

soon after being planted, the young Asparagus plants being in a shallow trench, and a little ridge of soil being thrown up between the lines of Asparagus. These trenches are generally about 4 feet apart. Here, for instance, is a young plantation planted in March. In England, the Asparagus would be left to the free action of the breeze, but the French cultivators never leave a young plant of Asparagus to the wind's mercy whilst they can procure a bit of Oak stake about a yard long. But when staking these young plants they do not insert the support close at the bottom, as we are too apt to do in other instances, but at a little distance off, so as to avoid the possibility of injuring a fibre; each stake leans over its plant at an angle of 45°, and when the sapling is big enough to touch it or be caught by the wind, they tie it to the stake. The ground in which this system is pursued being entirely devoted to Asparagus, the stools are placed very much closer together than they are when grown among the Vines, say at a distance of about a yard apart. The little trenches are about a foot wide and 8 inches below the level of the ground—looking deeper, however, from the soil being piled up.

The young plants are placed in these trenches very carefully. A little mound is made with the hand in each spot where a plant is to be placed, so as to elevate the crown a little and permit of the spreading out of the roots in a perfectly safe manner. In fact they seem to be about as particular as regards depositing the young plants in the first instance, as a good Grape-grower is about his young Vines. They plant in March and April—using any kind of manure that can be had, but chiefly here, so far as I could see, the refuse of the town—the ashes, old vegetables, rags, and other matters, that the people throw before their doors, and which

the dust-carts take away in the morning. They are very particular to destroy weeds, and they also take good care to destroy all sorts of insect enemies in the mornings, especially during the early summer. Between the lines of Asparagus they plant small growing crops on the little ridges during the first years of the plantation, but are careful not to put the large vegetables there, which would shade and otherwise injure the plant. When they plant, they spread a handful or so of thoroughly-rotten manure over each root, and they repeat this every year, removing the soil very carefully in the autumn down to the roots, putting on them a couple of handfuls of rotten manure, and spreading the earth over again, so that the rain is continually washing nutriment to the roots. When doing this, they notice the state of the young roots, and where one has perished, or has done little good, they place a stick, to replace the plant the following March. Early every spring they pile up a little heap of fine earth over each crown. When the plantation arrives at its third year, they increase the size of the little mound, or, in other words, a heap of finely pulverized earth is placed over the stool, from which some

This figure shows the mode of planting and the depth of the successive annual earthlings given to the Asparagus, as grown in France. After four or five years' growth the ridges disappear, and the highest points of the grounds are those over the crowns of the roots.

but not much, Asparagus is cut the same year, taking care to leave the weak plants and those which have replaced others, to themselves for another year.

They cut the best of it when it is about an inch and a half out of the ground. Let us hear the French side as regards blanched Asparagus:—"In certain localities they do not yet value the distinction between blanched and green Asparagus, and occasionally prefer the last. That is an error very prejudicial to the consumer's interests. In the green Asparagus there is only the point edible; in the white it is often entirely so, and, moreover, it is infinitely more tender and delicate. All Asparagus cut when it is green is not fit to be eaten in the ordinary way, but may be used cut up small as an accompaniment to other dishes. To serve up green Asparagus is to dishonour the table! In the markets of Paris the green Asparagus is worth one franc a bunch, when the blanched is worth three francs; they do not eat it (the green Asparagus)—it serves for the manufacture of syrup of Asparagus.—V. F. Lebeuf."

When the plantation reaches its fourth year the little mound of blanching earth is increased to 15 inches in height, for then they expect to cut something worth while, and these mounds are made in the early part of March; and even after this, as they grow stronger the little mounds are increased; and they always keep a look-out for the feeble plants, with a view to replace them. To have Asparagus as it ought to be, they say you must cut every day, or every two days, according to temperature, so that it may be obtained at the right moment; indeed if they do not do this, the shoots become too high and too green. They place great importance on obtaining strong and healthy plants; and in the establishment which I visited they have three kinds, l'Ordinaire, La Hollaude tardive, improved, and La Hâtive d'Argenteuil. The first is described as very fine, the second very strong, and the last is the earliest, most productive, and best. Of course there are various modifications of the plan just described, and in several instances I saw two rows placed in a rather wide trench in an alternate manner. As to the size and quality of the Asparagus produced by this method there can be but one opinion.

Concisely: the French mode of cultivating this delicious vegetable differs from our own diametrically in giving each plant abundant room to develop into a large healthy specimen, in paying thoughtful attention to the plants at all times, and in planting in a hollow instead of a raised bed, so that as the roots grow up they may have annual dressings of enriching

manure. They do not, as we do, go to great expense in forming a mass of the richest soil far beneath the roots, but rather give it at the surface, which is consistent with the nature of the root.

The French mode of forcing *Asparagus* chiefly consists in digging deep trenches between beds planted for the purpose, covering the beds with the soil and with frames, filling in the trenches between the beds with stable manure, and protecting the frames with straw mats and litter to keep in the heat. In the beginning of November the pathways between the beds of *Asparagus* are dug up about 2 feet deep, and as much wide. Divide the soil coming from the pathway very carefully, and put about 8 inches thick of it on the surface of the bed. Fill up the trench with good new horse-dung, and place frames on the bed. The manure should rise as high as the top of the frames, and the lights be entirely covered with mats and litter, to prevent the heat accumulated in the frame from escaping. About a fortnight or three weeks after, the *Asparagus* begins to show itself on the surface of the bed. Many market gardeners cover the whole of the bed inside of the frame to a thickness of 3 or 4 inches with dung, to force the vegetation more quickly, but in this case the manure must be removed when the *Asparagus* begins to shoot. When the shoots are about 3 inches out of the ground they may be cut. The mats must be taken off in the daytime, but the heat must be well kept up or the roots and buds will fail to push. The beds are forced every second year only. The gathering of the *Asparagus* may continue for about two months, but no longer, or the plantation would be injured. When the gathering of the *Asparagus* is over, the frames and dung linings are taken away, and the soil which has been dug up from the alleys is put back again. The preceding applies to the forcing of the better qualities of *Asparagus* chiefly. A speciality is made of

Preparation for forcing *Asparagus*. The trenches are dug out and filled with stable manure, the earth being heaped on the beds. These are covered with rough frames, up to the edge of which the heating material is piled.

forcing the smaller sized *Asparagus*. It is in the garden of M. Caucannier, Place de l'Eglise, at Clichy, and a number of iron houses are there devoted to the culture. Indeed, if I mistake not, those in the Jardin Fleuriste are copied from them. There are frames within each house, just as in many propagating houses in England, and beneath them the *Asparagus* is forced for the markets, and in large quantities. The houses are heated by hot water, and the culture in other respects resembles that which is practised in forcing gardens in England—that is, when the plants are taken up to be forced indoors or in pits. The disturbance weakens the roots a good deal, and by this method the large table *Asparagus* is never forced. M. Caucannier and other growers produce it specially in a small state for soups, &c., but it is impossible to obtain in this way the large table *Asparagus*.

#### ASPARAGUS PESTS.

Foremost amongst the causes which tend to diminish the yield of *Asparagus* deserve mention the luxuriant growth of fungus on the part of the plant above-ground, the attacks of caterpillars on its roots, and the depredations of the *Asparagus* beetle, *Lema* (*Chrysonela*) *Asparagi*, L. Of these the most serious evil is the parasitic fungus. With regard to the beetle alluded to, it is not so much the insect in its perfect form which proves so destructive, as the larvæ. Great damage is often done to the plantations by the *Asparagus* beetle (*Crioceris asparagi*), which abounds more in some seasons than in others, and is sometimes very destructive in one locality and almost unknown in others. The larvæ feed upon the leaves, perforate the buds, and even gnaw the rind of the stems. When the beetle first appears it may be controlled, but if allowed to become established the task is hopeless. Whenever the eggs or the larvæ appear, cut and burn the plants as long as any traces of the insect are visible. The larvæ, beetles, and eggs are generally found from the middle of June to September;

its larva state continues only for about ten days, after which it descends into the earth to undergo its changes; and in three weeks the perfect beetle is formed, when it ascends the plants to deposit its eggs. The beetle, after eating into the vegetable, lays its eggs in the tender juicy portion of the stalk and leaves, and when the larvæ (the produce of the eggs) issue forth, they totally destroy those parts of the plant with which they come in contact. The most efficient plan of dealing with this insect-plague is to collect and "stamp out" the young brood, or better still, the full-grown beetles, before they have laid their eggs. The work of collection must, however, be carefully proceeded with, for with the slightest movement the beetles will fall down and conceal themselves in the earth. After a time they reappear, and, if permitted, will crawl again on to the plant, lay their eggs, and recommence feeding. In his war of extermination with the beetles, the *Asparagus*-grower has no better friends and allies than the birds. If he is wise, he does all in his power to attract and protect them.

Respecting the fungus, the first symptoms are observable in August. Small dark brown spots, which in a few days attain the length of a quarter to half a centimetre, appear on the stalks, and gradually assume a much darker shade. These spots are surrounded by the ruptured epidermis of the stalk, and are somewhat inflated. On close examination, vertical layers of small powdery spots are remarked under the epidermis; and it is their great accumulation here and there which causes the latter to burst. The injury done to the parts of the vegetable that are above the ground has an unfavourable effect on the roots, checking their development, and in the ensuing spring the yield of *Asparagus* will be found materially diminished by the premature death of many of the plants. As to the precise nature and proper designation of the disease, whether rust or another disease greatly resembling it, whether originating in (or greatly increased by) over manuring with nitrogenous fertilisers, and whether—as some maintain—never met with under the shade of trees, these are questions on which uncertainty prevails. Should it be ascertained on further investigation that the disease is not confined to *Asparagus*—and Dr. Birnbaum has noticed parasitic fungus almost identical in appearance on Couch Grass—the difficulty of combating the evil and preventing it from spreading will be proportionally increased. If it turns out to be rust, the spores alluded to are possibly the *Telento*, or winter spores, which first develop themselves in spring on another plant, and are afterwards found on *Asparagus* in the form of mycelium or spawn. On one point, viz., the dangerous character of the disease, there is unfortunately no room for doubt, and the grower has every reason to be careful that it shall not gain ground, or be imported into districts hitherto free from it. Above all things he must endeavour to prevent the discharge of the spores—the organs of reproduction—and, as soon as any signs of disease show themselves, his best course is to remove the parts attacked and burn them.

Wireworms are sometimes very destructive to the roots of *Asparagus*, but by means of dressings of salt, pieces of Carrots or Potatoes attached to a skewer, and buried a few inches in the ground near the crowns, they may be attracted and destroyed; these decoys should be examined once every two days or so. Snails and slugs often attack the plants in mild springs, just as they push through the soil, but they may readily be got rid of by dusting the ground with lime.

#### NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**The Chinese Yam.**—This plant, one of the many failures among the novelties offered for our kitchen garden, is of some use as an outdoor pillar or trellis plant, wherever a variety of such subjects is desired.

**Climax Potato.**—I have never yet seen this variety so handsome as Mr. Gilbert (see p. 269) describes it to be. Possibly there may be some mistake respecting it, as I am inclined to the belief that what he has for Climax must be Bresset's Prolific, which if not grown too large is very handsome, and a capital sort for purposes of exhibition.—A. D.

**Sowing late Peas.**—In thin light soils Peas do little good when sown in May and June, in the usual manner. The plan I have practised for many years is to take out narrow trenches, as for Celery, putting in the trenches 3 or 4 inches of good dung, digging up the bottom, and filling the trenches half full of soil. When the Peas are well up, add more soil until you get them in a level with the rest of the land. By doing this, and if a dry day, giving them one good soaking with water, and afterwards mulching them, they seldom suffer from drought.—R. GILBERT, *Burghley Gardens*.

### THE OPENING OF ALEXANDRA PALACE GARDENS.

On this day week, the 24th inst., a great flower show takes place here, and from that date, let us hope, may commence the opening of a long and prosperous career for this important public garden. We looked over the grounds the other day, and were very much pleased with the preparations for flower shows and horticulture. There is already erected and in full working order, one of the best constructed groups of glass houses we know of, quite a village of glass. To these houses we shall probably again return. The great flower show will be held in the transept of the palace, an excellent position for a flower show. The arrangement proposed by Mr. McKenzie is a novel one; the most important plants and groups of plants will be grouped in a series of large and massive tazzas and vases running the whole length of the transept. As we propose to have an illustration showing the effect of these, we reserve further comment on them for the present. There is an excellent collection of American plants from Mr. John Waterer, of Bagshot, who for so many years has sent his fine and well-

### WORK FOR THE WEEK. PRIVATE GARDENS.

**Pleasure Grounds.**—Amongst the most ornamental of shrubs at present in bloom are the *Pyrus Malus floribunda*, which bears a profusion of reddish flowers, and *Cytisus præcox*, plants of which, no matter how small, appear this year to bend under literally a load of cream-coloured blooms. *Rhododendrons*, *Azaleas*, flowering *Carrauts*, &c., are also in great beauty. *Roses* are covered with flower buds. *Pines* are beginning to grow, and in some cases, have been nipped by frost; *Grass lawns*, too, look beautifully green. Dead blooms under *Cherry* and other trees should be swept up; indeed, mowing, sweeping, hoeing, raking, clipping *Grass* edges, tying in shoots of *Clematises* and other climbers, and removing decayed flowers and seed-vessels from early *Rhododendrons* and *Azaleas*, form the principal operations in pleasure-grounds at present.

**Herbaceous Plants.**—Among plants now in flower is *Iris nudicaulis*, a dwarf young free-flowering blue kind; various forms of *panila* are also blooming well, as are likewise *Pansies* and *Violas* of different sorts. Of these, cuttings should be put in under hand-lights in the open border, and seedlings and early-struck cuttings of them should be transplanted. Double-flowered *Daisies* of various colours are amongst the hardiest of spring flowers and the most

Alexandra Palace and Gardens.

grown collection to the Botanic Gardens in the Regent's Park. This collection is arranged in a large tent, and will form an attractive feature in the grounds. As the prizes for the first great show are very large, and, in consequence, the show likely to prove one of the most important ever held, our gardening readers will find it well worth a visit. To the general public, the noble views which the gardens command of one of the most picturesque suburbs near London, and of London itself, must make Alexandra Palace well worth a visit, even if there were no other attractions there. Many of our readers will be pleased to learn that near the glass house department there is a piece of ground of some 15 acres, of which it is proposed to form an experimental and ornamental garden.

**Influence of different Occupations on Health.**—A recent paper read to the Institute of Actuaries of Great Britain, on this subject, shows the ratio of mortality per thousand persons from 25 to 60 years of age to be of gardeners, 10.4; masons, 17.6; beer sellers, 21.5; wine and spirit merchants, 24; inn and hotel keepers, 27. Between the ages of 45 and 65, 32.2 hotel keepers die for every 14.5 gardeners.

easily managed, and their continuity of blooming is almost equal to that of *Pansies*. Now, although in their greatest perfection, they must in many cases be removed to make room for the summer half-hardy bedding plants; therefore lift and divide them, and transplant them in nursery lines in the reserve garden, where, if well watered and partially shaded with branches or otherwise, they will soon start again into growth, and afford many blooms that will come in usefully for cut flowers. *Saxifrages* are seldom used except in the herbaceous border, properly so-called, and as alpinas, and as they are now coming into flower in quantity, they must be left undisturbed; they are, however, benefited by a mulching of decayed leaf-mould, which not only contributes nutriment to the plants, but saves them from drought. In the case of the fine-leaved kinds, do not permit them to flower, as it spoils their beauty. *Ranunculuses* and *Anemones*, now everywhere very pretty, should have their flowers picked off when they begin to decay. *Scillas* of the *sibirica*, *bifolia*, and *amœna* class, are ripening seed plentifully, which should be carefully preserved and sown as soon as gathered, or in the following spring. As these are self-sowing plants, the ground in their immediate vicinity should not be hoed but hand-weeded, so as to preserve the seedlings unhurt. *Scilla campanulata*, *nutans*, and their varieties are now at their best, and fine ornaments they are, for, being hardy, free-flowering, beautiful, and easily accommodated, whether in the border or shrubbery, they are suitable for

every garden. Narcissi past flowering are best left undisturbed until early autumn, if possible, but, if it is necessary to remove them at once, lift them carefully without mutilation of root or leaf, and transplant them in the reserve garden, watering them well, and shading them for some time afterwards with boughs, mats, or canvas. Of this great family, *N. triandrus*, though little known, is one of the most ornamental, being a small-leaved kind, with bright single canary-coloured blooms, that appear almost before any of those of the other members of this genus; and now that Narcissi blooms are about over for a season, these are still in perfection. If bushy plants of *Antirrhinum* are required, the main spike should be pinched out, but if early flowers are wanted, leave them alone. Divide and transplant, like Violets, the runners of *Omphalodes verna*; they enjoy a shady position. *O. Lucillæ* is one of the finest of our hardy garden plants, its light blue or mauve-coloured starlike flowers being just now exquisitely beautiful; it prefers a more open position than *O. verna*, which is quite at home in a semi-wild state, *i. e.*, amongst Grass, broken or decaying branches, and leaf-mould; indeed, it is frequently found in better condition near the edge of some rubbish heap than in the most cared-for positions.

**Specimen Herbaceous Plants.**—If for exhibition purposes these are generally grown in pots, and to have them well established they should have been potted last year. The pots should all be of one size, say 8, 9, 11, or 12-inch pots, as may suit special requirements. In order to have the pots well filled it may be necessary to insert therein several plants together, especially such small kinds as *Aubrietias*. Keep them at present in coll pits and have the pots plunged in cocoa-nut fibre or coal-ashes. If the flowers are backward keep on the sashes, but tilt them up a little, so as to admit plenty of air. The following are commonly used for exhibition purposes, *viz.*, *Veronica repens*, *Aubrietias* of different sorts, *Delphiniums*, *Tradescantias*, *Irises*, *Coronilla montana*, *Cheiranthuses*, *Dicentra spectabilis* and *eximia*, *Centranthus ruber*, *Iberis coreifolia*, *Astilbe japonica*, *Spiræa palmata* and *venusta*, *Erodium Manescavi*, *Betonica grandiflora*, *Aquilegia cærulea*, *californica* and *glandulosa*, *Campanula persicifolia* coronata, *Pyrethrum roseum* fl. pl., *Lychnis viscaria* fl. pl., *Phlox decussata*, and alpine varieties, *Primulas* of sorts, *Statice latifolia*, and others.

#### MARKET GARDENS.

The parching easterly winds of a fortnight ago did much injury to crops in general; newly planted Lettuces had a hard struggle for existence, and many of them succumbed. French Beans planted out from frames have suffered considerably, and even Cauliflowers and Cabbages newly planted have not escaped unhurt; indeed, before the rain came, means of irrigation being at hand, the water was turned on, and half a pint or so given to each Lettuce and Cauliflower plant as it was committed to the soil. In lining off a field for these, mark off precisely the distances at which the rows are to be apart; one man should then tread on the line just before the marker, and another should pull the marker along, thus four or five rows are marked at one time. This is not necessary the second time, for the man with the machine can come back pretty accurately without the line being set; but the third time the line should again be set, not because it is absolutely necessary, but to prevent bends in the field; so that one setting of the line is only required for every second draught of the rake or marker. In dry, rough land marking is hard work, especially if the drills must be made deep. Ridges for the first crop of Celery must now be formed about 5 feet apart, by casting out a trench about 8 or 9 inches deep, and putting some manure therein and digging it into the soil. On the ridges between the trenches scatter thinly some horn shavings, if they can be got, mixed with horse droppings, and plant Cauliflowers thereon. A top-dressing of this manure is very good for Cabbages and Cauliflowers. Fully expose Celery in frames, and supply water to plants in the open beds. Draw an iron-toothed rake over the drills containing French Beans, Beet, Mangolds, Peas, and Potatoes, so as to permit an easy egress of the shoots. With pieces of matting, tie Cabbages and Cos Lettuces, so as to cause them to heart more freely. Place wooden pegs beside the finest Cabbages, the heads of which may be removed for market, but the stumps retained for seeding purposes. Hoe and weed Onions, thin Parsnips, and also the earliest crop of Beet. To Cucumbers admit air but sparingly whilst the cold is so great, pinch the shoots as required, water well, and protect the frames at night with plenty of litter. Plant out Vegetable Marrows under handlights and vegetable baskets, and protect them well with litter, especially those under the baskets. Before planting them holes should be made, and a barrowful of fermenting manure put therein, over which some soil must be placed; the plants may then be covered with handlights and litter. Expose as freely as possible Tomatoes in pots and frames, and clear away Mushroom ridges, unless required for growing Tomatoes against.

## SOCIETIES, EXHIBITIONS, &c.

### ROYAL BOTANIC SOCIETY.

(MAY 14 AND 15.)

THE first of this society's great summer exhibitions this season took place on this occasion, and was favoured with dry weather, though cold. The exhibition itself was most attractive, the great conservatory particularly gay, and the grounds pleasant, as one might expect at this season of the year. Their Majesties the King and Queen of the Belgians, Prince and Princess Teck, and other important personages, honoured the exhibition with their presence on the morning of the first day.

**Stove and Greenhouse Plants.**—These were well represented. In the class for nine, Mr. Baines, of Southgate, was first, with immense plants of *Eriostemon nerifolium*, *E. cuspidatum*, *Azalea Duc de Nassau*, carmine; *Azalea magnifica*, a cloud of pure white; *Boronia pectinata*, *Aphelaxis macrantha purpurea*, *Erica Cavendishii*, *E. ventricosa coccinea* minor, and the finest variety, as well as by far the finest specimen of *Anthurium Scherzerianum* in the whole exhibition. These plants, especially the hard-wooded greenhouse ones, were from 4 feet to 6 feet in diameter and of proportionate height. Mr. Ward, of Leyton, who was second, had somewhat similar plants, with the exception of a specimen of *Statice profusa* some 4 feet in diameter, and laden with bloom. In this class Mr. Herrington and Mr. J. Wheeler had equal third prizes awarded them; and although their plants were smaller than those of their more successful competitors, they were, nevertheless, well-grown and flowered. In the amateurs' class for six Mr. Baines was again first, with a fine group, in which was a large specimen of *Ixora coccinea*, with trusses of bloom some 6 or 8 inches in diameter; also a plant of *Hederema tulipiferum*, nearly 6 feet through and 4 feet high; *Azalea Distinction*, a plant of *Boronia pinnata* about 4 feet through, and the same in height; and a very large specimen of *Erica Cavendishii*. The second prize in this class was awarded to Mr. Chapman, Rugeley, in whose group was a plant of *Pimelea spectabilis*, 5 feet through and a little less in height, quite a mass of bloom; also some good *Chorozemas*, a fine plant of *Clerodendron Balfourii*, a Heath, and an *Azalea*. Mr. G. Wheeler, Regent's Park, was third, with plants of a similar description. In the nurserymen's class for six, Mr. B. S. Williams, Upper Holloway, was first with *Aerophyllum venosum*, *Aphelandra macrantha purpurea*, *Polygala acuminata*, *Azalea Stella*, *Anthurium Scherzerianum*, and a large Heath, all large and well-bloomed. Messrs. Jackson & Son, Kingston, were second, with a fine collection, in which was a grand plant of *Pimelea Hendersonii*; also a well-bloomed example of *Rhododendron Countess of Haddington*. Mr. Wm. Cutbush, Barnet, was third.

**Orchids.**—These were unusually fine, for not only were the specimens large, but they were uncommonly well-flowered. In the amateurs' class for the best single specimen, Mr. James, Isleworth, was first, with a plant of *Cattleya Mossia*, having some two and a half dozen flower-spikes on it in full perfection; Mr. Chapman was second with a splendidly bloomed plant of *Phalaenopsis grandiflora*; and Mr. Ward, of Leyton, was third with *Oncidium ampliatum majus*. The best specimen Orchid in flower from nurserymen was *Dendrobium infundibulum*, from Messrs. Jackson & Son, with twenty flower-spikes on it. The first prize for nine exotic Orchids was won by Mr. B. S. Williams, in whose group was a superbly bloomed plant of *Cypripedium caudatum* with nineteen flowers on it, *C. barbatum* superbum with some five dozen blooms, *Cattleya Mossia* with twelve flower-spikes, *Saccolabium retusum* with four flower-spikes, a plant of *Phalaenopsis grandiflora*, and some *Vandas*. Mr. Wm. Bull Chelsea, was second, and Mr. G. Wheeler third. For six Orchids, Mr. Ward was first with *Phalaenopsis grandiflora*, having three large, compactly-set flower-spikes; a plant of *Oncidium sarcodes*, having three very large and well-furnished flower-spikes; *Cypripedium villosum*, *Dendrobium nobile*, *Lycaste Skinneri*, and a fine plant of *Odontoglossum Phalaenopsis*. Mr. Hill, The Poles, Ware, was second with the extremely beautiful *Dendrobium Falconeri*, furnished with thirty expanded flowers, and several unopened buds; *Cattleya Skinneri*, with nine flower-spikes; *Vanda suavis*, an immense plant, with eight flower-spikes; and one of *V. tricolor*, with seven spikes; a *Phalaenopsis amabilis*, and an *Odontoglossum luteo-purpureum*. Mr. T. Godfrey, Ankerwyke, Staines, and Mr. J. Wheeler were awarded equal third prizes.

**Roses.**—Those furnished by Messrs. Paul & Son and Mr. Turner were in splendid condition, both as respects fine foliage and brightly coloured flowers, of which there were from four to seven dozen on each plant, the plants themselves measuring from 4 feet to over 5 feet in diameter. Mr. Turner was first in the class of six kinds, with *Celine Forestier*, President, Mad. Victor Verdier, Charles Lawson, *Souvenir d'un Ami*, and *Souvenir de la Malmaison*; Messrs. Paul & Son were second. For nine Roses, distinct, Messrs. Paul & Son were first, with magnificent plants, and the same firm were also first in the class of twenty Roses in 8-inch pots, the other successful exhibitors being Mr. C. Turner and Messrs. Veitch & Sons.

**Azaleas.**—These comprised some good kinds as well as large and well-flowered plants, though in point of size they were scarcely so large this season as we have seen them in former years. In the amateurs' class for six Mr. Chapman was first, with *Leopold the First*, *Mars*, *Juliana*, *conspicua purpurea*, *lateritia*, and *President*; Mr. G. Wheeler was second, and Mr. Herrington third. In the nurserymen's class for six Mr. C. Turner was first, with *Miltou*, *Hooibrunkii*, *Flag of Truce*, *Reine des Roses*, *Marie Vervaene*, and *Wm. Bull*; Messrs. Jackson & Son and Messrs. Lane & Sons were second and third. For twelve Azaleas Mr. C. Turner was first, with a group of small but finely managed plants; other

winning groups came from Messrs. Ivory & Son, Dorking, and Mr. G. Wheeler. In the amateurs' class there were also some fine plants in 12-inch pots. Beauty of Surrey, exhibited by Messrs. F. and A. Smith, of Dulwich, was literally a gem, its flowers being pure white, of good substance, and its shape exquisite.

**Rhododendrons.**—These consisted of forced hybrids, the first prize for twelve plants being won by Messrs. Lane & Sons, with some well-flowered plants, and the second by Mr. G. Wheeler. For nine plants Mr. Roe, Roehampton, was first, and Messrs. Lane & Sons second. Some nice plants of *R. Countess of Haddington* and of *fragrantissimum* were exhibited amongst miscellaneous collections of plants.

**Heaths.**—These were good, though, owing to the schedule specifying that the pots, except in one class, should not exceed 12 inches in diameter, there were fewer large specimens than usual. In the amateurs' class for twelve, Mr. Ward was first, with splendid plants, amongst which were *Erica profusa*, *tricolor elegans*, and *ventricosa grandiflora*; Mr. G. Wheeler was second. For twelve Heaths from nurserymen, Messrs. Jackson & Son were first, with *E. Lindleyana*, *odora rosea*, *depressa* (fine), *ventricosa grandiflora*, *v. minor*, *tricolor*, *Wilsoni*, *Devoniana*, *mundula*, *Victoria*, and *Cavendishii*; the same exhibitors were likewise first for half a dozen specimens, and Mr. Ward was second.

**Pelargoniums.**—These were excellent; indeed, the specimens of show Pelargoniums exhibited by Mr. Ward were models of skilful cultivation; they were in 8-inch pots, trained almost flat, from 4 to 5 feet in diameter, and literally smothered with flowers, open and opening. To these a first prize was deservedly awarded; the kinds were *Alabama*, *Rose Celestial*, *Lady of the Lake*, *Atalanta*, *Royal Albert*, *Patroness*, *Lady Canning*, *Emperor*, and *Rob Roy*. Mr. James also exhibited successfully in this class. From Mr. W. Bull and Mr. T. Pestrige, Uxbridge, came collections of beautiful tricolor Pelargoniums.

**Calceolarias.**—Of these there were only two groups, but both were particularly fine; that from Mr. James contained a first-rate pure yellow large-flowered kind called *Canary*, the other group came from Messrs. Dobson & Son.

**Liliaceous Plants.**—Mr. Ware, of Tottenham, exhibited a group of these, in which were *Scilla hyacinthoides* and others, *Tulipa Breyana*, *Fritillaria persica*, &c. Mr. C. Turner showed some well-flowered plants of *Lilium auratum*.

**Hardy Herbaceous Plants.**—Of these there were some interesting collections: the first prize for twelve kinds was won by Mr. Parker, Tooting, with *Alyssum orientale*, *Paeonia officinalis* fl. pl., *P. tenuifolia* fl. pl., *Phlox frondosa*, *P. subulata*, *Aubrietia purpurea grandiflora*, *Iris nudicaulis*, *Astilbe* (*Spiraea*) *japonica*, *Cheiranthus Dillenii*, *Primula cortusoides amena*, *Iberis correuifolia*, *Veronica repens*, and *Convallaria majalis variegata*. Mr. Ware was second, and Mr. G. Wheeler third. Various groups of hardy flowering and ornamental leaved plants were shown by Mr. Ware, and amongst them, in addition to many others, were *Viola lutea major variegata*, a yellow variegated-leaved kind; *Mimulus cupreus*, a red-flowered, very dwarf pretty plant; *Smilacina bifolia*; *Primula involuta*; the new *Aquilegia aurea*; *Delphinium nudicaule*; *Erythrina Cottiana*, a red-flowered, attractive sort; *Oxalis floribunda*, bearing a great profusion of white flowers; *Erinus hispanicus*, a reddish-purple flowered, pretty alpine or wall plant; *Orchis fusca*, well bloomed; and *Gentiana verna*.

**Bedding Plants arranged for Effect.**—In the centre of the exhibition was a group of hardy plants, tastefully arranged, from Mr. Ware; set within an edging of Grass was a band of *Phlox frondosa*; then belts of Pansies, Polyanthuses, Succulents, Pinks, Carnations, and other spring flowers, relieved here and there by a few taller growing, graceful plants, some of which were also placed at the back. A green groundwork was obtained by means of a free use of *Sedum acre* and of *Spergularia pilifera*, thus relieving the eye from too dense a mass of colour. Messrs. E. G. Henderson and Son showed several boxes of cut flowers of Tulips and spring flowers in this class.

**Stove and Greenhouse Plants arranged for Effect.**—Messrs. Rollison and Sons, Tooting, who were first in this class, showed an extensive collection of excellent and valuable plants. Towards the back were placed tree Ferns, Palms, and tall *Dracenas*; and in front, tastefully intermingled amongst other things, were specimens of *Alocasia Lowii*, *Adenandra fragrans*, *Cupania undulata*, a good plant of the variegated variety of *Pandanus javanicus*, *Kentia Forsteriana*, and other small Palms; *Saccolabium ampullaceum moulineusei*, *Dendrobium Devonianum*, and, as a margin in front, the beautiful silvery-leaved *Echeveria pulverulenta*. Mr. E. Morse, Epsom, was second, with a good group of Palms, Ferns, Heaths, and many other flowering and fine-leaved stove and greenhouse plants, particularly a large specimen of *Ananassa sativa variegata*.

**Palms and Ferns.**—Mr. B. S. Williams showed a fine group of Palms, as did also Mr. T. Godfrey and Mr. Wm. Cutbush, of Barnet. Of Ferns, Mr. B. S. Williams had a grand group, consisting of *Cyathea princeps*, *Cybotium regale*, *Dicksonia antarctica*, *Gleichenia Spelunca*, and *G. decarpa*, and a fine specimen of *Adiantum Farleyense*. Other contributors also showed nice groups, amongst which were several kinds of *Adiantum*, *Blechnum*, *Lomaria*, and filmy Ferns, together with several kinds of tree Ferns.

**Clematises.**—Mr. Noble, of Sunningdale, Bagshot, furnished a large collection of early-blooming kinds, including not only the older varieties, but also several new kinds of great merit. Worthy of particular mention amongst the latter was one called *Charles Noble*, a decided acquisition, with large purplish violet flowers, tipped with red; this promises to take the same place amongst early-flowering sorts that *C. Jackmanii* occupies amongst late-blooming kinds. Early Clematises are for the most part of a

pale lilac or white colour; but in *Charles Noble* we have very dark coloured, large, and fine flowers. Other new kinds consisted of *Mrs. Villiers Lister*, a fine white, with a purplish pink bar near the base of the petals; *Madame Albani*, a well-formed, large lavender-coloured flower; *Mdlle. Torriani*, a beautiful blush flower; and *Mdlle. Kellog*, a pure white, well-formed flower, with blunt petals—a fine variety.

**Miscellaneous Plants.**—Mr. B. S. Williams staged an effective group of Ferns and Orchids, amongst which were good plants of *Miltonia bicolor*, *Saccolabium retusum*, with two fine spikes, and a profusely-bloomed plant of *Maxillaria lutea alba*. Messrs. Lucombe, Pince, & Co., exhibited a group of Heaths, *Dracenas*, *Dioffenbachias*, *Azaleas*, &c., and a fine example of *Maranta tubispatha*; also another large collection of Ferns and Orchids, and a small plant of *Puya Altensteini* in flower. In another miscellaneous collection of plants furnished by the same exhibitor were the beautiful *Chianthus Dampieri* in flower, a pretty plant of *Pandanus Veitchii*, a nice specimen of *Ananassa sativa variegata*, *Marantas*, *Higginsias*, *Palms*, &c. An extensive group of Roses was shown by Messrs. Lane & Sons, and a group of miscellaneous plants by Mr. R. Jeal, Regent's Park. Several seedling *Gloxinias* were shown by Mr. Stone, Regent's Park, and Mr. Ware sent a group of *Sempervivums*, prominent amongst which was a plant of *S. arachnoideum*. Messrs. Ivory & Son, Dorking, exhibited a pretty little silver-leaved Ivy called *Hedera Dorkingensis*, and Messrs. E. G. Henderson & Son furnished a group of tree Caruations. Two brace of Cucumbers were sent by Messrs. Minier, Nash, & Nash, 60, Strand.

**Certificates of Merit.**—These were awarded to the following:—*Oncidium fuscatum* (Veitch), a pretty little purplish-flowered Orchid. *Masdevallia Lindenii* (Veitch), one of the most brilliant of cool house Orchids. *Demonorops fissus* (Veitch), a graceful and very handsome Palm. *Phoenix rupicola* (Veitch), another graceful Palm. *Phycosperma Keilii* (Veitch), a strong-growing, handsome *Geonoma*-like Palm.

*Platyloma brachypterum* (Veitch), an extremely pretty little Fern. *Platyloma bellum* (Veitch), somewhat like the former, but dwarfier. *Vresia reticulata* (Bull), a strong, compact-growing Bromeliad. *Encephalartos regalis* (Bull), a vigorous, stiff leaved, fine Cycad. *Encephalartos villosus ampliatius* (Bull), a strong-growing sort, with very large, spreading fronds.

*Demonorops palembanicus* (Bull), a very graceful Palm. *Colax jugosus* (Bull), a pretty Orchid, the sepals of which are creamy white, and the petals and lip striped and spotted with violet.

*Dracena Shepherdii* (Bull), a strong-growing sort, with broad, bronzy, green leaves, edged with a pale, copper-coloured band. *Dracena splendens* (Bull), a compact-habited, dark, copper-coloured kind, the old leaves of which are banded with bright red, a colour which is strikingly conspicuous in the young leaves.

*Cattleya Mendelii* (Williams), one of the most magnificent of the genus. *Aradia Sieboldi aurea reticulata* (E. G. Henderson), a yellow, variegated sort, at once pretty and effective.

*Astilbe* (*Spiraea*) *japonica aurea reticulata* (E. G. Henderson), an extremely pretty variety, beautifully variegated with yellow, and a welcome addition to our collections of hardy plants.

*Canna tricolor* (E. G. Henderson), a finely variegated form of *Canna*, the leaves of which are green and yellow, ribbed and veined with dark red or copper colour.

Variegated *Otaheite Orange* (Paul & Son), one of the best variegated forms of the Citron family we have yet seen, the creamy white variegation on the leaves being distinct and clear, and the plant free and vigorous in growth.

*Azalea Apollo* (Turner), flowers large, white, faintly streaked with red—an excellent variety.

*Rose* (H. P.), *Madame Laclarme* (Turner), a French Rose of great promise, flowers white with blush centre.

*Polyanthus Ceresus* (Ware), a large and showy yellow ground kind, with a deep orange eye.

*Polyanthus Parisine* (Ware), a large white ground coloured sort, with a primrose centre.

*Pansy Pluto* (Ware), one of the darkest of dark-coloured Pansies, fine in form and velvety in substance.

*Primula acialis*, var. the *Giant* (Ware), a large double-flowered yellow Primrose.

## COVENT GARDEN MARKET.

MAY 16TH.

CONTINENTAL and other foreign fruits and vegetables are now better and more abundant than they have been lately; English grown Strawberries and Grapes too are improving in flavour, colour, and ripeness. A few Melons have made their appearance, and Cucumbers are plentiful and good. Young Potatoes, English and foreign, are moderately abundant.

**Prices of Fruits.**—Apples, per half sieve, 3s. to 5s.; Apricots, 2s. to 3s. per doz.; Cobs, per lb., 2s. to 2s. 6d.; Cherries, per box, 3s. 6d. to 6s.; Gooseberries, per quart, 1s. to 1s. 6d.; Grapes, hothouse, per lb., 10s. to 15s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 6s. to 12s.; Peaches, per doz., 1s. to 36s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 8s. to 12s.; Strawberries, per oz., 9d. to 1s. 6d.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 3s. to 6s.; French, 2s. to 8s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, per bundle, 9d. to 1s. 6d.; Cabbage, per doz., 1s. to 1s. 6d.; Carrots, per bunch, young, 1s. 6d., old do., 8d.; Cauliflower, per doz., 3s. to 6s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 6d. to 2s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz. 1s. to 2s.; Mushrooms, per pottle, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 6s. to 8s.; pickling, per quart, 6d.; Parsley, per doz. bunches, 6s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 3s. to 6s.; Potatoes, per bushel, 5s. to 10s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsify, do., 1s. to 1s. 6d.; Savoy, per doz., 2s. to 3s.; Scorzoneria, per bundle, 1s.; Seakale, per basket, 1s. to 2s.; Shallots, per lb., 8d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, old, per bunch, 3d. to 6d., young do. 2s.

## THE GARDEN.

—o—o—o—  
 “This is an art

Which does mend nature: change it rather: but  
 THE ART ITSELF IS NATURE.”—*Shakespeare.*

—o—o—o—  

### THE GARDEN IN MAY.

THE system of flower-gardening so long followed by us has been notoriously destructive of the charms of the garden in spring, and equally so to those of the May or early summer garden. And even where “spring gardening” has been extensively adopted, and the parterre made gay with early-flowering bulbs and annuals and perennials, the beauty which a garden should exhibit in May is often seen but to a small extent. Thus the miles of Hyacinths and Tulips in the flower-garden along Park Lane being now out of flower, the whole of that vast strip of garden is a blank, so far as flowers are concerned. We need hardly urge that this should not be so. No garden, even if freely embellished with spring and summer bedding plants, should, or need be, poor in interest in May. To guard against that we have merely to plant freely a good variety of the numerous shrubs and low trees that flower at this season, and to cover the often bare surfaces of shrubberies and beds of shrubs with the numerous hardy flowers that bloom now. We must not depend on the merely formal set of beds, forming what is generally called the “flower garden,” if a garden is to be thoroughly enjoyable at this or at any other season. To confine our main efforts to the embellishment of such is of necessity to deprive ourselves of that varied and changeable life which is the charm of a true garden. We have seen some private gardens this year in which a few simple beds and small groups of Hyacinths produced a better effect than the enormous areas of those bulbs planted in the parks. In the small gardens alluded to the very small space devoted to these bulbs would not be much of an eyesore till they were replaced by other flowers, whereas when a large and formal flower garden is thus embellished, a lapse of weeks occurs when the year is in its freshest dress. This all points to the fact that the ornaments of the garden should be more of a permanent and varied character. This they may be without encroaching on the space or beds necessary for a tasteful display of “bedding-out.” And this kind of decoration is only seen at its best when so placed that it is relieved by an abundance of the verdure both of grass and shrub and tree. Where bedding plants and formal flower gardening are not important considerations, there need be no doubt that the most beautiful of early summer gardens could be made. What lovely results might we not attain, for example, if the pains now bestowed on grouping and growing bedding plants, which only beautify the garden for a season, were devoted to the best modes of cultivating, and the most artistic ways of grouping, the numerous families of hardy plants that flower in the open air at this season! It may appear to some that the plants and shrubs and trees we refer to require no “cultivation:” nor would they, if allowed a fair field to grow, but this is not their fate as a rule. Look in most shrubberies, and see the fine subjects which, from overcrowding, shade, &c., have dwindled so that their full beauty is never seen. Every day we see things stifled in shrubberies, which, with sufficient room for root and light for branch, would be each a picture. Surely a bush of one of the fine shrubs that flower in May is as well worthy of being grown into a perfect specimen as anything ever grown in the greenhouse or stove! Then as to kinds; how much we should gain by paying more attention to these. As the cultivation

of hardy shrubs and trees involves almost no expense, compared with that necessary for plants grown in a more artificial state indoors, all the known ornamental species should be in every country garden where there is room for them. Half the gardens in the country betray a disgraceful poverty as regards the variety of hardy early-flowering trees and shrubs grown. And, even where the species are liberally planted, there is seldom due attention paid to the varieties. Look, for example, at the Lilac—sweet and fair as any flower we have, and only seen in a few forms in our gardens. Yet there are in France several dozen good varieties of this valuable shrub. A difference that specifically, or to a botanist, may appear of no account, is often of the highest importance in the garden; as, for example, the brightly-coloured form of the common Flowering Currant of the mountains of North-Western America—its brilliancy in the shrubbery makes it a far more valuable plant than the older form. And there is scarcely a species long introduced into our gardens of which gardeners have not detected and propagated varieties more or less valuable. Therefore, not only should those who wish their gardens to be worthily adorned at this season take care to have all the species known to be ornamental, but study also to secure their good varieties—often more valuable, as has just been shown, than the original forms themselves.

As to arrangement, that is a subject quite in its infancy. The gardener is not yet an artist; he must become so if the art is to advance. Pictures formed by the accidental grouping of a few wild plants we may often find in our woods and lanes and hedges; they rarely occur in our gardens except by accident. That it is perfectly easy and practicable to make such in our gardens without in the least interfering with the convenience of either gardener or owner, there need be no doubt. The materials our garden flora now affords for picture-making in spring and early summer are both numerous and varied, and the living pictures that may be made by combining and grouping them in a more artistic and natural manner than is at present the rule, are innumerable. To this phase of the subject we shall again return; and should we happily find any good examples which can be well shown by engravings we will illustrate them.

In conclusion, we cannot do better than name a few of the more important plants which are generally in full beauty at this season, viz., Alyssums, Snowy Mespilus, Andromedas, Anemones, Columbines, Arabises, Aubrietias, Berberries, Cherries, Wallflowers, Clematisses, Solomon's Seal, Corydalis, Hawthorns, Japan Quince, Cytisus, Daphnes, Alpine Pinks, Dicentras, American Cowslips, Doronicums, Epimediums, Ericas, Fritillarias, Genistas, Geraniums, Gentians, Geums, Rockets, Candytufts, Irises, Kalmias, Linums, Honeyuckles, Lithospermums, Honesty, Lupins, Lychnises, Magnolias, Horse-chestnuts, Maluses, Muscaris, Forget-me-nots, Daffodils, Orobuses, Paonies, Pansies, Poppies, Phloxes, Polemoniums, Primroses, Prunuses, Lungworts, Pyrethrums, Pyruses, Rhododendrons, Raunculuses, Rock-roses, Saponarias, Saxifrages, Scillas, Spireas, Lilacs, Globe-flowers, Tulips, Veronicas, Viburnums, Vincas, Violets, Weigelas, Anthericums, Dentzias, Erodiums, Jasmynes, Sedums, Menziesias, Ornithogalums, Potentillas, Achilleas, Adonises, Campanulas, Collinsias, Cotoncasters, Galegas, Day-lilies, Pentstemons, Silenes, Tradescantias, Trilliums, Aponogetons, Arenarias, Azaleas, Calthas, Convallarias, Double Daisies, Erinuses, Exochorda grandiflora, Menyanthes trifoliata, Nemophilas, Omphalodes, Pernettyas, Ribes, Sun-roses. There are scores of other plants less common than these, which we could have added to the above list.

## NOTES OF THE WEEK.

— IN many of the Rhododendron beds near the Serpentine in Hyde Park, there are now in flower, beneath the shrubs, numbers of Pheasant-eye Narcissus, Wallflowers, &c., gracefully embellishing ground usually left bare. It is a decided improvement. We hope the Narcissi, &c., will not suffer from the usual digging in autumn.

— AT last we have seen an alpine plant creditably staged at a flower-show. A little carpet of the beautiful *Dianthus alpinus*, dotted all over with flowers, was shown by M. Ware this week, at Kensington. If the many fine species of alpine flowers now in cultivation were exhibited in equally good condition at our flower-shows, these plants would soon become as popular in our gardens as they deserve to be.

— THE Potatoes, as well as other things, have suffered from the recent frost. In the Chiswick Gardens a singular result has been observed, namely, that Potato plants of the same species display a capricious tenderness under frost, some of the individuals, as of the Lapstone Kidney, &c., exhibiting perfect hardiness, while others succumbed speedily. This would point to the fact that every plant, like every man, possesses a special constitution.

— AT Chiswick House, notwithstanding the coldness of the season, the beds in the flower garden were furnished with their summer occupants some three weeks ago. Owing to the beds being narrow, they have been well protected with evergreen branches, so that injury from frost and cold winds has been avoided, and the plants are now starting freely into growth. Such early planting, however, cannot be universally recommended; but at Chiswick House circumstances require the gardens to be at their best in June and July, consequently early planting must be resorted to, and the uncertainty of the weather guarded against.

— OUR correspondent, Mr. J. Luscombe, of Coombe Royal, Devon, sent to South Kensington on Wednesday, last, two of the most beautiful and remarkable shrubs we have ever seen. These were two kinds of *Embothrium*, literally swarming with their bright coral-red flowers. They are said to attain 18 feet high in his garden in the open air. Being so distinct from anything else that grows in the open air with us, they are worth going a long journey to see them. Those who have gardens in mild districts would do well to try these *Embothriums* in their collections.

— HER MAJESTY has conferred the honour of a Civil Companionship of the Bath on Professor Owen. As our readers are aware, Professor Owen, when he touches on botanical subjects, shows the same power of lucid reasoning and exposition with which the scientific world is so familiar when he deals with the subjects long ago made his own. He is also an enthusiastic gardener, and we know of few gardens more charming than that in which his pretty cottage stands on the edge of Richmond Park. This garden, of which we gave an illustration (see p. 117, Vol. II.) has been a favourite haunt of Dickens, Thackeray, and many other distinguished men.

— A VERY destructive frost occurred in London and many other districts on last Monday night—10° of frost were registered at Chiswick. Apples and small fruits have been destroyed to a large extent. Every unopened bud of the Strawberry has been quite cut off. In the Rhododendron nurseries in Surrey, the young growth has been much injured. In the Midlands the damage has not been so great.

— BITTERLY cold nights, with the wind set fast in the east for some time past, have made vegetation quite three weeks later than usual. Nevertheless fruit crops in the Eastern Counties are promising, especially Apricots and Damsons, both of which have set abundantly. Apples are in full bloom, and have leaves sufficient to keep it from the cold. As for bedding-out, it must be late. Glass, mats, and boughs are as requisite as in March. Even *Calceolarias* wintered in cold frames, and with no covering but glass, have become yellow in leaf, by having the glass removed for *Pelargoniums*. On the evening of May 19th, we are informed by Mr. Henry Taylor that Yorkshire was visited by a frost of 20°, which severely damaged Potatoes and fruit blossoms. Of late years we have seldom more than one month free from frosts, that month being July.

— AS we led our readers last week to anticipate (see p. 370) the special exhibition of stove and greenhouse plants for the Davis Memorial Prize at South Kensington, on Wednesday, though supported only by one exhibitor, Mr. Baines, of Southgate was highly satisfactory, and demonstrated very clearly that only a little more tact and enthusiasm are necessary to rid our flower shows of the sticky and half-leafless specimens which for some years past have disgraced them. Judged from any point of view, Mr. Baines' exhibition was eminently satisfactory, but as the result of less than three years' cultivation, they were simply magnificent. Fancy *Ixora coccinea*, a dense bush, more than 3 feet in height, and as much in width, with upwards of 100 heads of bloom on it, some of them 8 inches in diameter, and you will be ready to exclaim

"prodigious!" *Boronia pinnata*, *Hedera tulipifera*, and *Aphelexis macrantha rosea*, all densely bloomed and superbly coloured, and you have plants which a Queen might be proud of. With these were a matchless *Dipladenia amabilis*, quite dense in colour, *Epacris miniata splendens*, wreathed in bloom, and a grand *Clerodendron Balfourii* in superb condition. We congratulate Mr. Baines upon his triumph, for though his supremacy was unchallenged, the victory is none the less on that account. These plants take one back to the early days of the "one shift" system of plant growing, and we hope the council will have the courage to do full justice to the revival.

— THE best Oranges now in Covent Garden Market come from Valencia, and very delicately flavoured they are.

— THAT fine yellow *Columbine* (*Aquilegia aurea*) shown at Kensington the other day, is a distinct and handsome plant, with fine clear yellow flowers, making it worthy of association with the very finest species of *Columbine*.

— A NEW genus of Bamboo-like plants is reported to have been discovered by M. Balansa in New Caledonia, and dried specimens of it have been deposited by him in the herbarium of the Muséum at Paris. An account of this and of other New Caledonian plants will shortly be published by MM. Brongniart, Bureau, and Balansa.

— SPRING Turnips are always welcome. France is now, and has been for many weeks past, supplying us with a thick and tapering kind almost like a small Beet in shape, but white as snow. This is the famous *Navel* of the French; it is much esteemed in cookery, boiling much more tenderly than our early Turnip.

— MR. RICHARDS, who has for some years been assistant-secretary to the Royal Horticultural Society at South Kensington, is about to give up that situation; and, as a mark of respect for his services, the society has made him a life member. He has, we believe, accepted an appointment under the Royal Commissioners.

— THE *New York Tribune*, which has an able fruit-growing editor, lays down the following golden rules for those who plant Pears for profit:—1. Grow standards and not dwarfs. 2. Plant trees not more than two years old, and thrifty yearlings are still better. 3. Plant not less than fifty trees of any one kind. 4. Confine the list for market to six varieties or less.

— AMONG the crowd of plants now making our flower markets gay, we notice *Rhodanthe Manglesii*, especially the white variety, the silvery flowers of which have a most charming effect, either for decoration, bouquets, or button-holes. The plants spring-raised are not well grown, but the pretty everlasting flowers are none the less acceptable on that account.

— IN the great avenue of Horse Chestnuts, at Hampton Court, we have seen no tree bearing such fine flowers as one growing on the margin of the lake at Chiswick House, the flower-spikes of which are from 12 to 16 inches in length, exclusive of the footstalks, and the blooms individually are well coloured. To a good soil and a never failing supply of moisture we are doubtless indebted for this result.

— A WILTSHIRE correspondent has sent us an extremely beautiful seedling *Polyanthus*. It has a conspicuous orange eye, surrounded by a well-defined belt of bright magenta, set in a field of deep velvety maroon. The general complaint is that *Polyanthuses* are too much alike; but here we have a welcome innovation, which may possibly be the forerunner of quite a new race of *Polyanthuses*.

— AGAVE *Jacquiniana*, one of the large specimens of American Aloe at Kew, is now throwing up a strong flower-spike. It has been removed from the Succulent plant house to the great Palm stove, where it may now be seen. The plant is in vigorous health, and the flower-spike, which is already some 8 or 10 feet high, is making rapid progress. Some weeks must, however, yet elapse before the plant will be in flower.

— THE opening of Alexandra Palace and Park this day will be an event of importance, adding, as it does, a new place of amusement and recreation to Londoners, especially to those in the great and rapidly growing northern suburbs. The palace, situated in a beautiful park of over 220 acres, occupies the summit of a range of hills which have been aptly named "the northern heights of London;" and, extending as they do from Hauptstead to Mnswell Hill—a sweep of over four miles in length—they constitute a natural limitation to the already overgrown city. The view from the terraces, both on the north and south sides of the building, is very extensive. On a clear day, the Crystal Palace at Sydenham and the Surrey hills can readily be seen. The distance apart of the two palaces is exactly twelve miles, and it is a curious fact that the six miles' radius round Charing Cross intersects both buildings. The flower show, as far as we can learn, will be well supported. The new railway in connexion with the whole of the Metropolitan system, and running direct from King's Cross to the central transept of the Palace, was virtually opened to the public this week.

## THE FLOWER GARDEN.

### DATISCA CANNABINA.

By the casual observer, the subject of the accompanying illustrations might readily be taken for a rigid perennial form of the ordinary Garden Hemp. Hence its very appropriate specific title, and hence also does this very fact recommend it for more general cultivation, seeing that we have few plants that present a more graceful contour than the giant form of our common Garden Hemp. The *Datisca* is dioecious, or rather is said to be so; but seeing that, from the female plant, I have raised some seedlings before I was the happy possessor of its consort, I have a suspicion that occasionally, in the female flowers, stamens are developed; in fact, I have found some myself—many abortive, but some few perfect. So that Presenius, who recorded the occurrence of fully-developed seeds, independent of the male plant, was right; but in basing a theory of embryology without fertilisation thereon, he was evidently wrong. The species of which the representations are here given is the only one I have yet seen in cultivation. It is a native of the south-east of Europe, and is perfectly hardy; besides which important item it possesses such a vigorous constitution and such a powerful root-hold, the hempen character being as characteristic of its rope-like roots as are the leaves of

which are not; for in a batch of seedlings I have, obtained mostly from *Polyanthuses* which had been crossed by both the ordinary wild Cowslip and the cultivated Primrose, I find plants that defy classification under any one of the three classes just given; in fact, the Primrose runs into the *Polyanthus*, and the latter into the Cowslip, rendering determination impossible. I expect Mr. Dean and many others (myself included) would confine the Primrose to kinds which produce one flower only on each stem, the calyx being tubular instead of inflated, as in the *Polyanthus*, while the Cowslip in an ordinary way differs from both in the umbel of flowers being pendent, *i.e.*, hanging mouth downwards, and in the calyx being much enlarged. Then, again, the Oxlip differs but little in form from the *Polyanthus*, except in being mostly of the normal colour; but cultivation or hybridisation has removed many of these distinctions, and one of the most useful Primroses I have (a single crimson one) produces quite as often umbels as single flowers, both being met with on the same plant; and this is by no means a solitary freak or confined to one year, but has been the same for several years and on several dozens of plants. Now, I ask, is this a Primrose or is it not? I need hardly say that I also find amongst the seedlings alluded to some having the same peculiarity, while the ordinary Cowslip here has become red in colour, and instead of being drooping is partially erect, some of the flowers merging, by various degrees, into those of the *Polyanthus*. Now it is not so easy to determine from the above what is a *Polyanthus*, any more than what is a Primrose; and what is still more difficult, what is the Oxlip. For

the plant itself, that it is qualified to hold its own with all comers, and, if placed in a border, to bid defiance to the most energetic of skilful spade-drivers. I have said—if placed in a border, but this is not its proper location; it is, above all others, a plant adapted for the grassy margin of an irregular shrubbery, and will be rendered all the more effective if planted on the face of a grassy slope, where its deep-seeking roots will soon defy even the most protracted drought; nor is any margin of open soil between it and the adjacent turf requisite. It grows to a height of 5 feet in our clay soil, and used to attain even a greater size in the light sandy soil at Kew. The male plant is decidedly the most vigorous and graceful of the two—the terminal panicles of flowers being less dense, otherwise, in foliage, there is little difference. They both have one important qualification, that they require no artificial supports; in fact, their numerous stems (a well-established old plant will make a score or two) should be always allowed to display their beauty without let or hindrance.

Hull Botanic Gardens.

JAS. C. NIVEN.

### WHAT IS A PRIMROSE?

THIS question is mooted I see by your correspondent Mr. Dean (see p. 360), and without entering into any controversy there may be about the plants exhibited at a late Metropolitan show, I confess that I am unable to say, in many instances, which are Primroses and

the sake of distinction I have been calling a "hose-in-hose" variety of the ordinary wild Primrose colour by this name, not that it is botanically right, but by way of distinguishing one of the most ornamental members of the family from the others, and one which I cultivate (or rather intend to do so) largely, on account of its remarkably free-flowering qualities; as a late one it has all the beauty of the double yellow with a tenfold means of multiplying itself. But the most useful Primrose which I grow is the single white, the earliest and most prolific bloomer of the whole lot. We had several hundreds of plants of it in flower long before Christmas, and long before the wild one made its appearance, although both had the same advantages. This, I expect, would be pronounced a Primrose, properly so-called. The only one that I have had for any number of years that presents both the single-stemmed and umbel form is the common one alluded to; and as the Primrose or rather Primula family is evidently in the ascendant, perhaps some one will be good enough to set us right in their nomenclature. On visiting a friend some few days ago who is very fond of these flowers, I found he was trying to fertilise some of them with the pollen of *P. cortusoides amœna*; and his alpine Anemone had also undergone a similar ordeal. The kinds which we grow here out-of-doors include *P. denticulata*, which stands the winter tolerably well, but suffers from slugs; *P. cortusoides amœna*, and *P. japonica*. I need say no more in reference to this matter, on which most of my fellow cultivators know little more than myself; but, I repeat, if some one sufficiently acquainted with the subject will be kind enough to define the kinds, in so far as relates to the first three mentioned, I shall be glad, for I confess my inability to do so.

J. ROBINSON.

## PENTSTEMONS.

A CONSIDERABLE period having elapsed since a former trial of these useful border flowers took place, and a large number of novelties having been raised in the interim, it was determined that another trial should be made this season (1872). The varieties grown were contributed by Messrs. Downie, Laird, and Laing; they bloomed satisfactorily; and several awards equivalent to first-class certificates (indicated by the mark §) were made by the Floral Committee. For the selection given at the end of this Report, I am indebted to Mr. Spinks, foreman at Chiswick, who has had the plants under observation during the whole of the blooming season. The varieties are classified according to the colour of their flowers.

## FLOWERS NEARLY WHITE.

- §BRIDESMAID.—Nearly pure white, free and good habit.  
 LADY COUTTS LINDSAY.—Creamy white, robust but tall; fine flower.  
 DELICATUM.—Nearly white, shaded with rose; throat white; rather small flower, free.  
 AUGIER.—Nearly white, shaded with pale rose; throat large, creamy white; of a pleasing shade; free.  
 GEORGE BRUANT.—White, shaded with very pale purplish rose; throat large, open, pure white; free.  
 SNOWDROP.—White, free-flowering, and good.

## FLOWERS ROSE-COLOURED.

- QUEEN VICTORIA.—Tube rose and white, clear rose segments; throat white; showy, free.  
 LEAH.—Rose, large.  
 MONARCH.—Rose; throat white, with heavy crimson pencillings.  
 FLOWER OF THE DAY.—Very pale rose, washy; white throat; not desirable.  
 §JOHN POW.—Rose-colour; throat white, with dark red stripes on the lower part; free, compact, and good.  
 MRS. A. STERRY.—Pale rose, with white throat; free-flowering and pretty, but small.  
 LADY BOSWELL.—Very large pale rose; throat large, open, white; free-flowering and distinct.  
 PAULINE DUMONT.—Rose-colour, with pure white throat; free.  
 BESSIE ANDERSON.—Clear pale rose, the throat very pure white; of good shape; tall and straggling, otherwise good.

## FLOWERS BRIGHT PINK OR CARMINE.

- §JAMES ROHSCHILD.—Rosy crimson, striped and shaded with purplish crimson; good habit and free.  
 DR. HOGG.—Bright rose; white throat striped with crimson, upper segments shaded with lake; fine, free, and good habit.  
 CHRISTINE NILLSON.—Bright reddish carmine; white throat; dwarf, but rather weak in habit.  
 COLIN BELL.—Bright rose; throat shaded purple, with dark maroon stripes; very free, and good habit; distinct.  
 GRANDIS.—Large, rose; throat white in the upper part, thickly striped and shaded crimson-purple below; fine.  
 ALFRED PILLEN.—Very bright carmine, the throat shaded with dark maroon, and striped on the lower half.  
 APOLLON.—Very bright carmine; the throat pure white, with a few purplish-crimson stripes; late, and fine habit.  
 §A. SAINTE-CLAIRE.—Dull rose; throat large, white, very heavily shaded and striped with crimson; of good form, very free, and good.  
 §POLLY KING.—Bright rosy carmine; throat white, striped with dark carmine; free and good habit.

## FLOWERS RED.

- JOHN MORRIS.—Red tube and limb, the three lower segments large, upper ones small; throat white, heavily shaded, and with a few stripes of dark maroon; slender growth.  
 ELEGANS.—Red, with small tube and narrow segments; dull white throat with crimson stripes; not desirable.  
 MRS. R. CLARK.—Dull red; the throat white, with a few dark stripes; small, with narrow segments, but free.  
 FLORENDIA.—Bright carmine red, of fine form; throat white, thickly striped with crimson, shaded with lake; dwarf and good.  
 §M. MONTON.—Bright scarlet, very free, and of good habit; a fine variety.  
 HENRY KING.—Brilliant carmine-scarlet; throat very large, white, striped and shaded with crimson; fine variety, free.  
 MISS BAILLIE.—Flower long, brilliant scarlet, the throat creamy white, with a few crimson stripes; fine shape, free and good.  
 §SURPASSE VICTOR HUGO.—Bright red, large, and finely formed; throat nearly pure white; good habit; very free.  
 ROYAL SCARLET.—Good bright red, with striped throat; free and good.  
 §BONS VILLAGEOIS.—Very large, with broad smooth segments;

bright red, the throat striped with a darker colour; exceedingly free; one of the best.

§STANSTEAD RIVAL.—Large, crimson-scarlet; throat white, with a few crimson stripes, the edge of the upper segments shaded with mauve; very robust, free-flowering, and late; a grand variety.

§M. LEMOINER.—Tube dark purplish red, segments red; throat pure white, very heavily striped with dark maroon on the lower part, slightly striped above, shaded on the margin of the throat with bright lake; very fine form, and distinct; good habit, and free. The finest for individual beauty of all Pentstemons.

## FLOWERS ROSY PURPLE.

- LE CONQUÉRANT.—Pale rosy purple; throat large, white, with few stripes; very free.  
 §SUNRISE.—Purplish rose; throat white, with dark stripes on lower segments, shaded with purple; distinct and good.  
 ROSY GEM.—Pale purplish rose, throat pure white; rather washy.  
 AGNES LAING.—Very clear pale rosy purple, of good form; throat pure white; good, distinct, and free.  
 §MRS. CAFOR.—Pale rosy purple; throat large and white; very free, good foliage, and robust.  
 MRS. MOON.—Pale purplish rose, very clear throat; fine form, robust, tall, and distinct.  
 §JAMES ADAMS.—Clear rosy magenta, of fine form; throat pure white, with few stripes; excellent, distinct, and free.  
 §LE KHÉDIVE.—Dark purplish rose, heavily shaded and striped with maroon; free, distinct, and good.

## FLOWERS PALE PURPLE.

- MRS. McHARDY.—Pale lavender; white throat, with few stripes, rather washy.  
 §JOHN McPHERSON.—Bright mauve; throat nearly white, with a few purple stripes; very pretty, free-flowering, but of weak habit.  
 JAMES FORREST.—Pale shaded mauve, laced and striped with a darker colour; ill-shaped and small.  
 RICHARD LENOIR.—Like Mrs. McHardy in general appearance and colour, but with a purer white throat; free.  
 LOVELY.—Lilac, with pure white throat; rather small, free.  
 §GEORGES SAND.—Bright lilac tube and segments; throat white, with few stripes; very free, showy, late.  
 CANDIDATE.—Pale washy purple; a small ill-shaped flower, not desirable.  
 GUSTAVE LAMBERT.—Clear pale purple, large, and of good form; throat large, white, peculiarly shaded on lower segments; distinct and good; an improvement on Georges Sand.  
 BOURBAKI.—Pale clear purple; white throat, with few stripes; very robust, free.  
 §W. M. ALEXANDER.—Fine purple; throat white, with a few stripes; very large and well formed, free, robust, and good.  
 MARIE HELD.—Clear pale purple-shaded on white; throat shaded, large, striped with the same colour; free, and compact.  
 MADAME LOUIS SCHMIZER.—Pale magenta; throat white, a badly shaped flower; not good.  
 CHAMPION.—Large pale magenta; throat large, pure white, with dark purple stripes; very free good habit, and pleasing.  
 PETRUCHIO.—Pale mauve; throat shaded and striped with dark purple maroon; small flowers, but free.

## FLOWERS DARK PURPLE.

- MAGENTA.—Fine clear purple; throat of the purest white; fine form, robust, excellent in habit; the best of the colour.  
 REGALIA.—Purple, the throat white, with few stripes; rather a weak grower.  
 M. E. WYNNE.—Clear purple, throat white, with few purple stripes; very badly shaped.  
 STANSTEAD SURPRISE.—Dark purple tube and segments; throat pure white; free and good.  
 VICTOR.—Dark purple; throat white, shaded on the upper part with purple, on the lower part marked with a few darker stripes; free and good.  
 W. E. GUMBLETON.—Clear true purple, throat white; a bold flower, free and good.  
 CZAR.—Very clear bright purple, throat white, with dark purple stripes; compact habit, and free-flowering.  
 MULBERRY SUPERB.—Dull dark purple, with brighter segments; throat white, slightly striped on the lower part; free.  
 ROBERT PENN.—Dull maroon-purple, small; throat heavily striped with dark maroon; good.  
 ATRACHON.—Very dark purple, throat white, with broad dark maroon stripes; free-flowering.  
 BLACK KNIGHT.—Dark purple, with white throat.

## FLOWERS DARK MAROON-PURPLE.

- §DE SAINT PAUL.—A large cupped flower, dark maroon-purple;

throat white, with dark stripes on lower part; a fine, showy, free, robust, late variety.

§COL. LONG.—The counterpart of the last variety in general colour, but with whiter throat, better-shaped flowers, and not so late; fine and good.

EMILE CHATÉ.—Purplish crimson; throat white shaded and striped dark crimson; flowers of good shape; habit compact.

ARTHUR STERRY.—Small rosy purple; throat white, with few stripes; not very good.

GEORGE ARNER.—Very dark dull purple; throat heavily striped and shaded with dull maroon on lower half, white on the upper half; habit robust, very free, and late; a fine variety.

BLACK PRINCE.—Intensely dark purple, with very large and broad segments of the same colour; throat shaded and striped heavily with a darker colour; a very bold and desirable variety, of the darkest type; good.

#### A SELECTION OF TWENTY OF THE BEST PENTSTEMONS.

Long, De Saint Paul, George Arner, Georges Sand, James Adams, Lady Boswell, Lady Counts Lindsay, Le Khédive, Magenta, M. Lemoisier, Queen Victoria, Stanstead Rival, Victor, W. M. Alexander.—*T. Moore, in "Proceedings of the Royal Horticultural Society."*

### IRIS IBERICA.

THIS handsome plant is far easier to cultivate than most persons imagine. It is perfectly hardy, and not at all fastidious as to its requirements. I have seen it planted in frames

Flower of *Iris iberica*.

and in the open air, in light soil and in heavy, and in all cases it has grown freely and flowered. From my experience of this plant, I find it thrives best in a rich fibrous loam, in which it can send its long roots deep into the soil. The rhizome does not require to be planted deeply—just below the surface seems to be sufficient. In most cases I have found the roots perish when planted deeply. The rhizome, during the winter, is very impatient of moisture, and should be kept comparatively dry. To attain this end, I use coarse river sand, planting the rhizome completely in it, in the same way as many Cape and other bulbs are planted. By this means the rhizome is kept rather dry during the winter; and it is also a great assistance to the plant in summer, as the young shoots can easily force their way through. Under this treatment the plant grows more freely, and can be easily multiplied by division of the rhizome. It is admirably adapted for rockwork, or for the select border, and, when better known, will find a place in every garden. P.

**Bedding Petunias.**—The best way of managing Petunias in beds is as follows:—After the plants have made some growth in the beds, procure a lot of pliable Hazel rods, about 2 feet long and as thick as one's little finger; bend both ends firmly into the ground at suitable intervals all over the bed, so as to make a kind of trellis about 8 inches from the soil, which will look like a lot of small

croquet hoops all over the surface of the bed. The sticks of course need not be put in till the plants have made some growth and are showing symptoms of requiring some attention, and then train the shoots over the hoops, tying them down so as to form a neat, compact bed. This tying and bending down of the shoots will have a tendency to check rampant growth and induce a greater freedom of flowering. Without something of this kind, Petunias by September, when the garden ought still to be in full dress, will be getting straggling, and liable to be blown about by the wind; and this plan really does not involve much trouble. In fact, a bed of Petunias may be kept in good condition with as little or even less labour than Verbenas or Geraniums; for, what with pegging the one, and incessantly picking the other, they require almost constant attention. A man, with a stout plank sufficiently strong to bear his weight, with a couple of large flower-pots to support each end, will soon travel over a bed of Petunias and do the necessary training without putting a foot on the bed. It is, however, necessary to bear in mind that the trellis must be formed in time. Do not wait till the necessity for it is forced upon you by seeing, some windy morning, the shoots straggling on the Grass or over the Box edging, as the difficulty in putting matters right will then be tenfold.—E. H.

**Iron Flower Vases.**—Allow me to corroborate the remarks of Mr. Buchanan as to the adaptability of cast iron for plant vases. I much prefer them to either stone or composition vases for growing plants in the open air. I have had no experience with iron indoors, but I should, nevertheless, not hesitate to use pots made of it. For eleven years I annually filled seventeen vases, which were made of iron and 2 feet in diameter, with plants generally used for that purpose, and I found the plants to do perfectly—better than many others in the same grounds which were planted in white marble and rough sandstone vases. The success of those made of iron I always attributed to their holding more soil in the same space, and not to any advantage which iron has over stone. The vases were painted stone colour, and if dusted with sand when the paint is wet, no one, except upon close examination, could tell that they were made of iron. Such vases as those referred to were cast at the Colebrookdale Iron-works. Vases of this description need not be more than a quarter of an inch thick, and are not nearly so heavy as vases made of stone of the same size, and are not so liable to be broken when overturned. Composition vases of whatever sort are always cracking and falling to pieces with the weather, and lack solidity both in appearance and in reality.—W. DICK.

**Edging for Suburban Gardens.**—Adjoining a certain class of dwelling houses in and about large towns are plots of ground, often only a few feet square, in which flowers are grown; and in order to prevent persons from plucking the flowers, a gravel walk divides these little plots from the low palisade-bearing wall. Turf, tile, slate, and stone, have been used as edging for such gardens, with varying success, but by the following method a very pretty edging for such a position may easily be made. Place a layer of small flint stones on a level, a trifle lower than that of the gravel walk, draw a little soil between and upon them, lay pieces of Stonecrop alternately with London Pride, so that their tops may be nearly flush with the stones next the walk, then apply a little more soil, and put on another layer of stones, pressed a little off the perpendicular towards the bed, and plant as before. The Stonecrop partially hiding the flints forms a neat groundwork, while the London Pride, throwing its foliage and flowers above the whole forms a contrast at once pleasing and natural.—T. W.

**Aubrietias.**—I feel as if I could not let the spring, with all its beautiful flowers, pass away without a word or two in praise of Aubrietias, which last long in flower, delight in open, dry, exposed situations, and produce charming masses of warm-coloured blossoms. There are many varieties of Aubrietias in gardens, but probably all of them may be reduced to some half-dozen species; all of them are, however, beautiful, some of them eminently so. The oldest variety is the one called by some people *Aubrietia purpurea*, a pretty flower enough, but thrown into the shade by some of the other kinds. There is a well-known variegated variety of this, not of much value, except as a neat little rock plant. Then there is what is called *deltoidea*, which is very near, if not identical with *purpurea*. We have also *grandiflora*, a kind similar in colour to *purpurea*, but twice or thrice its size. This has a lax diffuse habit, which makes it a charming rock plant. There is a variety of this called *græca*, a fine plant, opening out at first a full purple, and dying off a lavender colour. Masses of this, with its various shades of colour, are very pleasing. There is also a fine variegated, large-flowered form of it. Then we have *A. spatulata*, *erubescens*, and *hesperidifolia*. The last of the Aubrietias I shall notice are *Mooreana*, *Columnæ*, and *Campbelli*. *Mooreana* is a compact little cushion-like plant, which, in its flowering season, is literally smothered with bloom. This has a shade of blue in it. *Campbelli* and *Columnæ* appear to me identical; but, like

Mooreana, they are among the loveliest of Aubrietias. The last three are well adapted for spring gardening purposes, being charming either in masses or as edging to beds of other plants. They are perfectly hardy, and will flower from March until June.—J. WILLIAMS.

GARDEN DESTROYERS.

VINE PESTS.

THERE is an old saying that "a taste of practice is worth a whole windbag of theory," and I can assure Mr. Pearson that the remedies I have recommended I have used with some of the finest collections of plants in England since 1832, without any of the ghosts he speaks of having arisen. Mr. Pearson says I recommended syringing with "a mixture of lime and sulphur." Where and when did I recommend this novel system of whitewashing? Until Mr. Pearson informed me of it it never struck me, and I should now certainly be sorry to deprive him of an idea so perfectly original. What I have used, and what I desired to teach others to use, was the vapour of sulphur and, in case of need, its resultant product—soluble or liquid sulphur. Either or both of these I have long found a perfect remedy for red spider and mildew in plant-houses of all kinds, and that without the slightest injury to either crop or foliage. Surely, it is unnecessary to explain that the vapour of sulphur and soluble sulphur are products very different from sulphur fumes. The latter are known to be destructive to both vegetable and animal life, but, by the process which I have recommended, the atmosphere of a house may be so thoroughly impregnated with the vapour of sulphur as to render it impossible for human beings to breathe it for any length of time and yet be quite innocuous to plants. But let it be understood that it must be vapour, not sulphur in an ignited state. And further, I may explain that under my rough-and-ready method of production the liquid sulphur will not be very potent. To make it of full strength two parts of quick-lime to one of sulphur should be boiled together in a close vessel, and then be decanted and closely stopped; but, in my case, I merely want the vapour, and, therefore, the clear liquid is not very strong. Mr. Pearson pins his faith to what is called "Gishurst compound." What is that but soluble sulphur and soft soap? At least for more than forty years I have known that those two substances, properly combined, are as safe a remedy for red spider and mildew as need be used. With Mr. Pearson's objection to crude sulphur I have nothing to do; sufficient for me is it that it has answered my purpose, and, if others abuse its use, that is their affair. And now for live fire: I grant that, in an hermetically-sealed house, it is a dangerous agent, but for the benefit of those whom it may concern, I may state that in the winter of 1850 I had, through the bursting of a boiler, every night for a fortnight, with 10° to 20° of frost all the time, one of the finest collections of stove and greenhouse plants in England, with nothing to protect them but external coverings, and the heat evolved by scores of pounds of candles and a number of braziers of charcoal and coke inside the houses. A chink of air at the highest part of the house, call it a chimney if you like, allowed the products of combustion to escape, and no harm was done. With such examples as these in my experience, I have no sympathy with those who make mountains of mole-hills; but, on the contrary, have a strong conviction that extreme caution is quite as likely to result in failure as a little whole-some daring. P.

**The Bullfinch.**—This is one of the most beautiful of our British birds, but unfortunately his mischievous proclivities render further eulogy regarding him impossible. Some of his friends (he has not many) attempt to form an excuse for his tree-disbudding propensities on the plea that he is searching for insects; but this cannot be substantiated. Be that as it may, he has certainly a weakness for the best and plumpest flower-buds of the Apricot and the Plum, which he prefers even to the buds of the Gooseberry and Currant. Even in a short space of time a pair or two of bullfinches, in winter or in early spring, will ruin a wall of fruit trees, or a quarter of Gooseberry and Currant bushes. Fortunately, however, compared with other finches, bullfinches are by no means numerous, although they appear to have been much more so than usual this spring, a circumstance possibly owing to the comparative mildness of the foregoing winter; for, notwithstanding the robust and burly aspect of bullfinches, they are, nevertheless, constitutionally delicate, and a severe winter proves fatal to great numbers of them. Bullfinches, moreover, are not greatly gifted with the power of keeping themselves free from danger. Their peculiarly plaintive and frequently uttered cry gives intimation of their whereabouts to birds of prey, as well as to wingless enemies, who are by no means slow to take advantage of the circumstance. Altogether, therefore, Mr. Bullfinch has a somewhat rough time of it; and he might justly sing that "Few and evil are his days," so short-lived are they. In confinement the term of his life seldom exceeds three or four years, and possibly this is not much exceeded when he is in the enjoyment of liberty. In a domesticated condition he soon becomes a docile, confiding, and

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Gentiana ancalis.**—This is at present the gem of the mixed border. Its lovely flowers of azure brightness almost hide the thick carpet of leaves below them.—D. T. FISH.

**Fritillaria delphinensis (Grenier). F. lutea (Bieb).**—The plant figured by Mr. Mogeridge under this name is one of the most ornamental of the genus, and is found in alpine pastures about Tenda and Limone in the Maritime Alps. Last June I had the pleasure of seeing a meadow high up in the mountains above Limone, adorned with hundreds of its beautiful orange-buff flowers, and some roots I brought home have flowered in my garden in the middle of April.—G. Maw, *Bentham Hall*.

**Narcissus triandrus.**—This is one of the loveliest of all Narcissus, producing charming bright canary-coloured flowers, the petals of which are reflexed, and the cup bell-shaped; the foliage is dark green, and grassy like. An ordinary garden soil will suit it, and it will succeed in the herbaceous border or on rockwork. It is considered to be a late-flowering kind, but in Mr. Parker's nursery, at Footing, it commenced flowering fully as early as any of the other members of the genus, and it has quite outlived them, for even now, it is the only flowering Narcissus we have, with the exception of *N. Bulboodium*.—J. D.

**Omphalodes Lucilia.**—Of the many hardy gems that grace our flower and alpine gardens, few surpass in loveliness this exquisite little flower. Its leaves are glaucous and smooth, those nearest the root furnished with a foot-stalk, and those near the end of the shoots sessile. Its flowers are of a bluish lilac or mauve-colour, marked with white, and about half-an-inch in diameter. It succeeds admirably in a sandy loam, enriched with leaf-mould in a partially shaded warm situation. In such a position a long succession of flowers from the first of May onwards may be looked for. In early spring or in autumn the plants may be increased by division, and seeds sown any time after they are ripe, or in spring.—CHAS. WILKINSON.

affectionate pet; and when in the full enjoyment of liberty, a glimpse of his gay and varied plumage flitting amid sunlit foliage, recalls distant scenes of early joyous boyhood, of Saturday half-holidays, sunny glades, and shady woods.—P. G., *Culford*.

**Cure for Red Spider and Thrips.**—It was stated, I think, in your columns, some time ago, that there was no cure for red spider when once it had thoroughly established itself. I thought so myself at one time, but I imagine that I have discovered an antidote, not only for red spider, but also for thrips and greenfly. This season red spider made its appearance in rather an aggravated form on a particular Peach tree here, almost as soon as the first leaves were well out. I had tried my liquid remedy on Cucumbers with success, and so I applied it to the Peach tree in question by putting a little in the water with which it was syringed every evening. The result is, that after a fortnight's application the spider has been completely subdued. In confirmation of what I say, I send you a shoot for inspection. You will observe that the first leaf on the shoot is covered with dead spiders, and that traces of them are on others, from which they have been dislodged, and that the leaves formed since are perfectly clean and healthy, showing that the liquid is harmless to the plant, while it is destructive to insect life. In fact, so far, I have proved that it may be applied repeatedly in a concentrated form to the most tender foliage without bad effects; but a weak solution, applied in the way I have stated, seems more

### ENTER A GARDEN, EXIT A NUISANCE.

IN the most southerly portion of that part of Paris which may be best indicated by naming the Boulevard du Temple, there was formerly to be seen, conspicuous for its unwholesome and repulsive-looking water, the Canal de l'Ourque—a place even more unsightly than canals passing through great cities usually are. It was a favourite resort of suicides, and there are few French novelists who have not in more than one of their sensational fictions described some tragic event in connection with it. Where such scenes were, the magic wand of an ingenious horticulturist has caused a garden to appear, removing from public view the unsightly canal without impairing its usefulness. The canal and its towing paths have been arched over at a sufficient height not to impede the traffic, which now takes place through a tunnel, and a handsome garden has been planted in the ground thus improvised above the course of the canal. The diagram No. 1 shows a section through the arched tunnel with the garden above, and also one of the tunnel roadways for returning horses or other purposes. This creation of a garden "without a site," as it were, may be fairly described as a new "hanging garden," a thing of beauty suspended over and veiling a public eyesore, so that, in

Section showing Canal, Garden, and Road.

than enough for the insects. It costs me about 3s. per gallon to make it, but that quantity diluted is sufficient for 200 gallons or more of water.—J. SIMPSON, *Wortley Hall Gardens*. [The leaves sent were quite free from living insects.]

**Crickets.**—I am much troubled with these pests in a small stove, heated by means of hot-water pipes. Can you or any of your correspondents furnish me with a remedy for destroying them? Last year I got rid of them by putting treacle in basins, into which they got and could not escape. We could then catch and kill them. At the present time we have literally swarms of them. Their chief food is *Lobelia speciosa* and *Dablias*.—J. B. [The remedy by which you got rid of the crickets last year is one of the best that can be adopted, and might be repeated now with the same success. Slices of bread and butter covered with Battey's Vermiu-killer Paste or Phosphor Paste might also be tried.]

**Bullfinches.**—The destruction committed by these little depredators in this neighbourhood is something alarming; in fact, our fruit trees are nearly ruined, the buds all up the branches being gone, so that not only is this year's fruit crop destroyed, but next year's as well. Vigorous action therefore must be taken if our fruit crop is to be saved. I would suggest that every proprietor of a garden should give one shilling a dozen for all bullfinches' eggs taken, as a means of getting rid of such destructive birds to fruit bushes. Taking the eggs would be the most humane way of destroying them, and would not injure the trees so much as shooting. The trees destroyed here are Gooseberries, Plums, and Apricots on walls.—C. RICHARDSON, *Galsdon, Surrey*. [Mr. Gilbert, of Burleigh, is obliged to Mr. Harrison Weir (see p. 345) for his correction in respect to bullfinches; nevertheless, as they have spoiled his crop of Gooseberries, he states that he can make no rash promises in reference to them on the score of humanity. On the contrary, he adds that he shall kill all that come in his way.]

theatrical phrase, the horticultural creator of the scene might fairly have said, on the completion of his work, "exit a nuisance, enter a garden." The scene painter and his slutter could not in fact have produced a more striking transition of effects.

Diagram No. 2 represents the ground plan of the garden over the Canal de l'Ourque. In the centre is a spacious basin surrounded by a handsomely moulded stone coping, and in the midst of the basin rises one of those handsome fountains, of which continental nations have the secret, and which it would seem that we insulars have not even the capacity to imitate—if we may judge from the wretched attempts in Trafalgar Square and Kensington Gardens. The central enclosure of this ingeniously created Parisian garden is terminated at either end, within the enclosure, by circular shrubberies, which, in a garden necessarily formalistic in style, are productive of a pleasing effect. Beyond are two rows of trees, forming handsome avenues, in the course of which occur handsome stone seats, and architecturally designed lamps, which are lighted at dusk during the winter season.

Diagram No. 3 represents a longitudinal section, showing the effect, in profile, of the central enclosure, the circular shrubberies, and the handsome fountain. This garden is a good example of what might be done by "Metropolitan Boards of Works" in many great cities less advanced than Paris, in

the art of city embellishment and improvement. In dirty, ugly, and unwholesome Berlin, for instance, what an improvement might be effected! what an embellishment achieved, by covering the course of the stench-emitting Spree with such a garden as that which now conceals a portion of the Canal de l'Ourque in Paris.

H. N. H.

## THE FRUIT GARDEN.

### PEACHES AND NECTARINES IN POTS.

BY THOMAS RIVERS.

Few fruit trees give more satisfaction in the orchard house than a choice selection of Peaches and Nectarines. When in blossom in early spring, the trees are so fresh and beautiful—they are so exceedingly prolific; and in autumn what can vie in beauty with a ripe Peach or Nectarine? And what, to the lover of fruit trees, can be more gratifying than to see his sideboard or dining-table decorated with Peach-bushes in pots, studded with their lovely and perfectly ripened fruit?

#### CULTURE.

If bushes of only a moderate size be required, 11-inch pots may be used. It is surprising to see the vigorous growth and fine fruit of Peach trees in 11-inch pots; for owing to the compost being rammed down, a large quantity of nutriment is comprised in a small space. I may as well, however, state, once for all, and for all descriptions of fruit, that, if fewer and larger trees be required, larger pots may be employed; thus, 13, 15, or 18-inch pots may be used with equal success. A Peach or Nectarine tree may thus, in two or three years, be made capable of bearing many dozens of fruit; but I must confess that my taste inclines to small prolific trees, because one can have greater variety in a small space; and small trees are pretty, and easily looked over, so that each leaf and bud, each blossom and fruit, is known. If Peach trees already in pots, and in a bearing state, can be purchased, so much the better for then a year is saved; but as such are more expensive than either "maiden" or "cut-down" trees, these had better be purchased. I may here state that "cut-down" trees are two years old, and, if nice healthy trees with fully ripened shoots can be found, they are better than "maiden" trees. But as they are not often to be met with, I will first give the treatment required by one-year-old or "maiden" trees.

#### PRUNING.

The trees have one shoot, more or less vigorous, which should be well furnished with buds towards its base. This shoot must be cut clean off with a sharp knife at the seventh bud from its base, and the tree then potted towards the end of October or early in November. This season is recommended, but it may be departed from; for my Peaches and Nectarines are sometimes not potted till March, yet they make fine growth. The following summer every bud will, or ought to, produce a shoot. If there are seven shoots the tree is formed for the season; they need not have their tops pinched off, but will merely require the laterals (small side-shoots) pinched off to within two buds of their bases, as soon as they are 1 inch long. This will induce the ripening of the shoots, so that by the end of the summer they will be full of blossom-buds. At the end of August the point of each shoot should be pinched off, and they will then only require the annual pruning, either in autumn or in spring, for which directions are given. If the tree puts forth a fewer number of shoots than seven, the tops of all should be pinched off early in June; each shoot will then put forth three or more young shoots; all that are not required to form the tree must be pinched off in the same way as laterals, leaving seven or, if the tree be vigorous, nine shoots to each tree. These trifling manipulations are easy to do, but difficult to describe; so, to make the matter as clear as possible, let us place a young tree before us early in June, with five branches, each 12 inches in length; then let us, with a sharp knife, shorten each branch to 9 inches; then, at the end of June, let us take the same tree in hand, and we shall find that each shortened branch has put forth two or three shoots; we must pinch these so as to leave on four branches two, and on one only one, making nine shoots, which as they grow should have their laterals pinched off regularly; they will then make vigorous trees in one summer, and form an abundance of blossom-buds. No other pruning is necessary the first season; and if abundant ventilation and syringing daily have been attended to, the fruit-buds will, towards the end of August, begin to be fully developed. The experienced gardener can at once distinguish them: such a person may prune his trees early in October. Let me endeavour to tell how to distinguish a fruit-bud, which, by the way, is the only bud to prune down to.

#### FRUIT-BUDS AND WOOD-BUDS.

Towards the base of each of your seven or nine shoots, you will

find four or five pointed single buds, covered with their brown coats: these are leaf-buds. Next to these, and higher up the shoots, are triple buds—a plump silver-coated one on each side, and a thin one in the centre: these plump silvery buds are blossom-buds, and the central one a leaf-bud, which produces a shoot so necessary to the well-being of the blossom-buds, that without it they would be abortive. Be sure to have on each shoot, if possible, nine to twelve of these triple buds, and cut off the shoot close to one of them; if this cannot be found at the proper place, so as to be able to form the foundation of a nice, regularly-shaped, bush-like tree, cut off the shoot at a leaf-bud. If the trees be pruned in autumn, the buds are difficult to distinguish; it will, therefore, be better for the beginner not to prune his Peach and Nectarine trees till February, or early in March, when every bud will plainly show its character; the blossom-buds by that time will have opened their silvery coats, and the bright pink will be peeping out. If the shoot be cut off at a single blossom-bud, it will die down to the next leaf-bud; this must, therefore, be carefully avoided.

#### SPRING PRUNING.

Let us now proceed with the culture of our maiden tree. A season has passed; it is early spring, say the middle of February, and our tree, with its nine branches of the last summer's growth, is before us; three of these should be cut down to within five buds of their basis, to give a supply of young shoots for the succeeding year, and six should be cut down, so as to leave on each branch ten or twelve triple buds. These are the fruit-bearing branches for the present season—and so it must be every year; a few branches, say one-third, must be cut in closely on opposite sides of the tree, to give young shoots, and the remainder left as above to bear fruit. Those shoots that have borne fruit will often require to be cut out, to make the tree dwarf and prevent its becoming naked, as the spurs die after bearing, unlike those of the Apricot and Plum, which continue to bear fruit for many years. Much will depend upon the sort cultivated, and the vigour of the tree. One thing must be borne in mind—do not let the tree become bare of young shoots towards its base, and tall and straggling. If pruned in spring, the nature of every bud may be seen, and the tree formed, by the proper use of the knife, into a fruitful beautiful bush. When the trees are in a bearing state, many short spur-like shoots, from 4 to 6 inches long, will be made every season on the stem and towards the base of the principal branches. These will be generally covered with single blossom buds and a terminal leaf-bud: they may be removed if too much crowded, but never shortened. From twelve to fifteen leading shoots should be left, in summer pruning, on each tree when in a full bearing state. I have thus endeavoured to follow the "maiden" tree to its fruiting state. The "cut-down" tree, which should have four or five branches, should be potted in autumn and pruned in early spring: each branch must be shortened to 6 inches; these will put forth numerous young shoots, which in June should be thinned out with a sharp knife, leaving nine or more shoots to be pruned the following spring, as above directed. If trees in pots three or four years old in a bearing state can be purchased, it is a saving of time; for, if they be potted before Christmas, a crop of fruit may be expected the ensuing summer. In such trees, the shoots intended to bear fruit, and covered with triple blossom-buds, may be shortened to ten buds, and those which are to make young shoots for the next year's bearing should be shortened to five buds.

#### SUMMER PINCHING.

Pruning of bush-trees by summer pinching only has been practised here to a large extent. As this is the most simple of all the methods of pruning known, and may be practised by any lover of gardening who does not mind employing his finger and thumb when walking in his orchard house, it is worthy of a few lines of description. A Peach or Nectarine tree of the usual bush-like form, two, three, or four years old, may be potted in the autumn. In March its shoots should be shortened to about half their length, forming the tree into a round bush. In May it will put forth young shoots. As soon as they have made four or five leaves, the fourth leaf, with the end of the shoot, must be pinched off, leaving three leaves, exclusive of one or two small leaves at the base of the shoot, which are without buds; every shoot must be thus operated on. In eight or ten days a fresh crop of shoots will show itself, for from the bud at the base of every leaf a shoot will spring forth. These, as soon as they are ready, must all be pinched down to three leaves, and so on all through the summer with every fresh crop of young shoots till the end of July; for if the pinching be continued till the end of August, a great number of the shoots will be a mass of blossom-buds, without a terminal shoot or leaf-bud; and although they may be cut out, and yet leave more blossoms than the tree can carry on to a fruiting state, it is as well to have most of the spurs with a terminal shoot or leaf-bud. If bush-trees are in very large pots, or planted in the borders of a large house, and it is desired to have

them increase more rapidly in size than pinching to three leaves will lead to, the pinching should be at the sixth or eighth leaf, leaving five or seven in every operation instead of three. This is applicable to all kinds of fruit-trees under summer pinching, when large trees are wished for. My trees, under this incessant pinching,

are sturdy bushes, full of blossom-buds, and quite pictures of robust health, and the fruit they bear is always large and high-coloured, owing to its full exposure to the sun. In March it will be good practice to thin out some of the numerous blooming spurs and clusters of blossom-buds with a sharp penknife, otherwise the trees will be too much crowded with blossoms. This thinning out may also often be done in summer with advantage; for, if the trees grow very luxuriantly, the young shoots become crowded, and the thick mass of leaves shades the fruit too much; in such cases the young shoots may be thinned out in the month of July, much to the advantage of the tree. This simple and charming method of pruning, only occurring to me in 1858, was fully carried out in the summer of 1859. I am quite at a loss to account for its not having been discovered earlier. As far as regards myself, I think it was the fear of inducing, by incessant pinching, too many young shoots to

break out that deterred me from practising it. Reasoning from theory only, I imagined it to be impossible for young shoots made in August to ripen, forgetting the warm autumnal atmosphere of the orchard house. I do not hesitate to assert that this simple step forward of pruning by incessant summer pinching is one of the most successful advances that have ever been made in fruit-tree culture under glass. I may add, that if by any neglect the pinching of the shoots in June and July has not been attended to, so that the trees have made shoots of from 2 to 3 feet in length, these may be shortened with a sharp knife to ten or twelve leaves. The bud at the end will then form itself into a leaf-bud, and even make some small growth, while all the buds below will remain fruit-buds, and quite dormant till spring. I tried this experiment in August, 1861. No anxiety need now be felt even by the lady orchard-house cultivator—no advice need be asked of the too-often-unwilling-to-give-it gardener. Thinning in early spring those pretty clusters of blossoms with a penknife (for they are always too numerous,

and at least half of them may be cut out), and at the same time shortening shoots that are irregular; and in summer pinching off the ends of the young shoots, always fragrant, so as to give symmetry to the tree and make it pleasant to look on, are all agreeable operations. The climate of the orchard house will do all the rest, and a Peach tree in a pot will bear fruit even under very adverse pruning circumstances, much more under a lady's loving, yet pinching, care. All that seems to be required is to make the tree symmetrical, and prevent its bearing too bountifully; for it must be borne in mind that fruit from a tree overloaded, whether under glass or in the open air, is never of fine flavour. Peaches, Pears, Plums, Apples, and indeed all descriptions of fruit, suffer in flavour to an extent scarcely thought of, if the tree be allowed to bear too many. It is better to have one dozen of Peaches large, and of fine flavour, than two dozen small and inferior; besides this, a tree suffered to bear too large a crop will be sure to fail the following season. There are two methods of cultivating these fruits in orchard houses, both equally favourable to their well-doing; one is to cultivate the trees in pots, the other to plant them in the borders of the houses. With the large houses, the most eligible form of tree to plant in pots is the pyramidal; this most interesting form succeeds better in pots than when planted in the borders; the roots being confined, the shoots are not so gross as those on trees planted in the ground, the sap does not rush to the top so rapidly, leaving the lower branches in a weakly state; in fact, it seems more regularly distributed, so that for many years a pyramidal Peach or Nectarino tree, in a pot from 15 to 18 inches in diameter, will gradually increase in beauty, and by the simple operation of pinching all the young shoots formed during the summer to two, three, or four leaves, a fruitful and beautiful pyramid, 10 feet or more in height, may be formed. Such trees, placed among others planted in the borders, are most ornamental, showing, as they will do if attended to, perfect cultivation. The health and fertility of such trees is kept up by giving them every season some fresh food in the shape of a rich compost formed of loam (if tenacious, all the better) and manure, thoroughly decomposed, in equal quantities. This operation should be performed about the

No. 2. Plan of Canal Garden. (See p. 395.)

No. 3. Longitudinal Section of Canal Garden. (See p. 395.)

ing, as they will do if attended to, perfect cultivation. This operation should be performed about the

last week in October, by removing the surface soil, generally a network of fibrous roots—to a depth of 4 inches, and replacing it with fresh compost of the description just given. The most important matter connected with the culture of trees in pots is keeping their roots dry during the winter months, so that they are not too much excited—they are never at rest; the shoots then become dry and ripe, and in a fit state to put forth their blossoms in spring, which, owing to the trees not being subjected to the great atmospheric changes incident to the open air in an English winter, they do with great vigour. To make success doubly sure, this dryness of the soil in the pots must be strictly attended to. The trees should be well watered when top-dressed, and again before the middle of November; they may then, if in the large pots I have mentioned, remain without water till early in March, when the blossom buds begin to swell. Many failures in the pot culture of fruit trees have occurred from the fears entertained by cultivators that trees must always have their roots in a soil saturated with moisture—the great evil of our English climate; for, if the roots of our fruit trees in the open air could be kept from the heavy rains of our winter months, we should have much greater success in the culture of the more delicate kinds of fruits. Before I leave the subject of pot culture, I must mention the necessity of giving the trees extra food during the summer months. This is best done by placing on the surface of the mould in the pot a layer of some rich compost, about 3 inches in depth at the outside, and made concave round the stem of the tree, so as to retain water. This compost may consist of manure chopped into small pieces, and saturated with liquid manure; or horse droppings from the roads, and kiln-dust from a malt-house, equal quantities, also saturated with liquid manure; the latter compost is the most valuable surface dressing ever invented, for not only do the roots of Peach trees come to the surface to feed upon it, but Vines, if dressed with it, show extraordinary vigour. If a Vine in a pot has a dressing of it from 6 to 8 inches deep (this must of course be supported by pieces of slate stuck inside the rim), the roots ascend rapidly, and seem to devour it with avidity, so that by the autumn a mass of this compost on the surface of the soil in the pot, in which a Vine has been growing all the summer, will be found a complete mass of fibrous roots, hard and compact, the virtue of the compost being seemingly absorbed.

#### PLANTING OUT OF PEACHES AND NECTARINES.

I have thus far endeavoured to give an outline of the pot culture of Peaches and Nectarines in unheated glass structures. The other method of cultivation, by planting the trees in the borders, must next be considered; this is neither more nor less than planting a Peach garden, such as one would do in Italy or in some of the States of North America. Still, as a glass structure is of more value than a piece of uncovered ground, care must be taken that it is made the best of. There is a peculiar feature in most stone fruits—their love of a firm soil. A light, porous soil is generally fatal to the health of a Peach tree, at least in the gardens of Europe. How the light soils of Buenos Ayres and other parts of South America act on the constitution of the Peach tree I am not able to say; I only know from report that the trees make good firewood. In orchard houses, I am now able to assert, with full confidence, that a firm border for Peach and Nectarine trees is a *sine quâ non*; there is no sound prospect of success without it; and I may add, that if such a border is calcareous, or can be made so by mixing one square yard of chalk to ten of the natural soil, so much the better for the fruit trees. In forming the borders, the soil should be refreshed with a slight dressing of manure, and then stirred to a depth of 20 inches—no other preparation is required. The trees should be planted in this rather shallow border, heavily watered, and suffered to remain for a week; at the end of that time the entire border should be gone over with a rammer, and rammed firmly down; a wooden rammer of about 10 lbs. weight will be found the best implement. The border thus rammed and levelled should remain solid, and never again be stirred, except to be slightly pricked with a fork in spring—early in March—to admit water to the surface roots of the trees. After being watered, a slight dressing of rotten manure, about 1 inch in depth, should be laid on the surface of the solid soil, and no other disturbance of it should take place. So obnoxious is the disturbance of the soil to the roots of Peach and Nectarine trees when planted out—although the inert surface mass of fibrous roots may be removed from trees in pots without injury—that I have seen, in an otherwise well-managed house, fine and well-grown half-standard trees quite bare of fruit, owing to the borders having been carefully dug 6 inches in depth in spring, every blossom having consequently dropped without setting its fruit.—*The Orchard House.*

A PROFESSOR'S wife, who occupied herself sometimes in assisting her husband in making casts of interesting objects of geology and

natural history (says a scientific contemporary), also for her own pleasure sometimes made flowers and fruits of wax and other materials; but notwithstanding that she had become quite a successful expert in this line, she found that almost always her efforts were criticised by her friends. Once, at a tea-party, she passed a large Apple round, and stated her confidence that this time she had been quite successful in her imitation of nature's product; but her friends were, as usual, not of her opinion. One criticised the shape, saying it would be more natural if it were not so globular; another criticised the colours, and said it was better than other imitations, but that she had not quite hit that natural indescribable peculiarity which distinguishes the natural Apples from the imitations: almost every one had some fault to find. After the Apple had been passed round and had come into her hands again, she ate it without saying anything. Her friends had been criticising a real Apple, but never afterwards criticised her imitations of fruit.

## THE ARBORETUM.

### ARAUCARIA IMBRICATA.

The subject of the accompanying illustration forms one of the most interesting trees in the grounds at Woodstock, the property of the Right Hon. W. F. Tighe, where there is such abundant wealth of arboricultural treasures as is to be found in few other places in Ireland. This fine Araucaria was planted nearly fifty years ago by Lady Louisa Tighe, by the side of a pretty oval Rose garden, and opposite it a match tree was planted at the same time, but that tree died more than twenty years ago. Owing to the fine, healthy appearance of this tree, it has been supposed that the subsoil at Woodstock was peculiarly favourable to the growth of the Chili Pine, and this induced Colonel Tighe to plant Araucarias extensively, even when they were expensive. It was soon discovered, however, that the clay-slate, combined with the iron pan, which is the natural formation of the home-grounds of Woodstock Park, was unsuited to the healthy development of the Araucaria, and, excepting the one great tree now figured, not another healthy Araucaria, out of all that were planted, can be found. The success attending the tree which has escaped has arisen from its having been planted on artificially made ground, formed when the Rose garden referred to was made. There is no mystery about this; the newly-made ground suited the natural requirements of the tree, and visitors to Woodstock Park may now see in this Chili Pine what rapid growth this noble tree will make in our climate when properly treated. In Ireland it is seen in almost every garden of any importance, but rarely in a healthy state if above 10 feet in height. This arises in a great degree from little regard having been paid to its natural wants when it was planted. The Chili Pine never loses its leaves except from disease or accident. It succeeds best on a rocky bottom, or on a thoroughly dry subsoil. In the wet seasons of 1861-62, the tree at Woodstock showed unmistakable signs of suffering from wet, and to remedy this a drain was put in on the upper side of the tree (the ground lies on a slope), to cut off the water above it. This drain was from 6 to 11 feet deep, and was filled to the top with stones. Decay was thus arrested, and the tree made a distinctly vigorous growth the following year. It was surface-dressed with peaty sods and granite chips, through which the upper roots of the tree ran like those of a Vine. In entering the drain referred to, the site of the match tree was cut through, and clearly showed that when the roots had left the bit of made soil in which the tree had been planted they perished, with the exception of a few thongs which had penetrated into the stiff natural subsoil. It is worth stating that Colonel Tighe so much appreciates the stately grandeur of this fine Araucaria, that, besides it, he has a fine avenue of this tree, and considerable plantations of it have been made on suitable sites, on which from thirty to forty loads of the best materials within reach have been put. At about 1 foot from the ground the girth of the tree now illustrated has increased annually at the rate of 2 inches. The girth of the bole is now about 7 feet; the height is about 50 feet, and last year it produced cones for the first time.

*Phœnix Park.*

CHAS. McDONALD.

THE GREAT ARAUCARIA IN THE GARDENS AT WOODSTOCK, KILKENNY—HEIGHT 50 FEET.

## JAPAN CONIFERS.

I HAVE been induced to make a few notes on this most interesting family of Conifers, in the hope that my doing so may lead to their being more generally planted. The eye never grows tired of a collection of them, presenting as they do an agreeable diversification which I think can scarcely be seen in any other class of the Fir tribe. Take for instance *Retinospora pisifera* and *obtusata*. These are fine handsome timber trees, growing from 70 to 100 feet high. The first, I find, grows faster than any other Conifer at this place. The habit of growth is very graceful, somewhat resembling that of the Decodar. It seems to love a moist situation, and on a well-drained bog is quite at home. I have observed that, although as a rule rabbits are particularly fond of this family of Conifers, they seem to care little for this species. *R. obtusata* is not by a long way so fast a grower, and, although it is represented to be by far the largest tree in its native haunts, it will never, I think, make so large a tree as *pisifera* in this country. I find *pisifera* to make an average growth of 3 feet to *obtusata*'s one. The character of *obtusata* is more that of a bush than of a tree, its graceful pendent branches forming handsome round heads of a light green, tinged with a purplish hue. Nothing can be better for winter decoration of beds, being so hardy and compact in habit. It also bears moving well. *R. obtusata* *nana* and its golden variety, *aurea*, are invaluable for planting in centres of round flower beds or for edging large ones, or forming the second or third row in middle-sized beds in winter. In a word, they are useful plants for many different purposes when from a few inches to 2 feet high. Instead of the ever and again repeated *Biota aurea*, both in large and villa gardens, let us have, like the Japanese, a goodly number of these *Retinosporas*, and also of *Retinospora pisifera aurea plumosa*. This is a great favourite of mine, and indeed of all who have seen it. It is much hardier than *Biota aurea* or *gracilis*; in fact, the whole family of *Retinospora* is much more so than the *Biotas* are. Where we cannot get a presentable tree of *B. aurea*, our eyes may often alight on the fresh, healthy, feathery golden heads of *R. pisifera aurea plumosa*. I cannot deny the beauty of *B. aurea* when in a healthy condition; but it must have a dry warm subsoil, and as little rain and frost as possible, to retain its beauty, and then to me it has an air of stiffness that is quite wanting in the *Retinosporas*. In wet, cold-lying situations, where light-coloured trees of this character are wanted, we use only the *Retinosporas*, excluding the *Biotas in toto*. There are other *Retinosporas* with something of the same aspect as *pisifera aurea plumosa*—*pisifera aurea*, for instance, a distinct and desirable variety, not quite so golden and more Heath-like in its growth. This and the three other varieties of *pisifera* are very distinct subjects as dwarf trees. Well may the Japanese so highly esteem them, and grow them so extensively in pots. A handsome plant of *R. pisifera aurea plumosa*, in a pot, was shown in the excellent collection of Conifers of the Messrs. Barron, at the late Royal Horticultural meeting at Birmingham. I believe most people, like myself, thought it the most striking plant of the whole collection. I was surprised to see but this one out of so many beautiful varieties of *Retinospora*. We all know a *Thuja*, a *Biota*, or a *Cypressus* as old friends, and see them every day, but in such collections we look more for something with which we are not so familiar.

I will now turn to quite a different type; it is the peculiar and interesting thread-branched Japan Cypress, *filifera*. I know of no Conifer anything like it in character. It might be well designated the Weeping *Retinospora*, and is very suitable, I should think, for planting in cemeteries. And how grand for placing in vases or centres of beds! It is like *Amarantus salicifolius* in its outline when trained to one stem (which it always should be) and well furnished at the bottom. Placed in a pot or vase, it will throw its curved thread-like branchlets over the sides in the most pleasing manner. I can recommend it with confidence to all who want a weeping tree of a small size. One more species is so distinct from the rest that one can scarcely believe it to be a *Retinospora*; it is *cricoides* (the Heath-like Japan Cypress). This assumes during the winter a beautiful tinge of purplish hue on a pale silvery ground, which with its tiny Heath-like branchlets presents a charming contrast to the other species. Its growth is rather slow, and conical in character, and it is well adapted for Italian parterres instead of the Irish Yew. Like all the rest it is very hardy, and bears removing well. It is a good pot plant, invaluable for small villa gardens, &c. It is no exception to the rest of the family in doing well on a drained bog; but unfortunately, the rabbits are particularly fond of it—so much so that out of scores planted here not one is left whole. I thoroughly believe, if there are rabbits within a mile of it, they will find it out. Out of their reach, it should be planted largely on rockeries, margins of mixed borders, &c., and in gardens where winter decoration is carried out. Nothing can be propagated with greater ease by cuttings under a hand-light in the autumn in a free, sandy soil, with good drainage, the soil

pressed firm, with an inch of sand on the surface. Set the cuttings about 2 inches apart, give a good watering, to settle them, and then dry off the surface moisture, and put on the light, which should be allowed to remain, unless damp makes its appearance, when it should be removed for a short time. This, with a little dry sand or charcoal sprinkled on the surface, will arrest the damp at once. Take care that they have little or no sun for some months after being planted. If all goes on well, they will be rooted by the following August. They can then be planted in brick pits, and shaded for a while until they are quite established. When hard weather appears they must be protected by old lights or wooden or straw shutters, always giving light and air when the weather is favourable. After spring they will well be able to take care of themselves without protection, if their other wants are attended to. The trouble of raising the stock at home ought not to prevent their being used largely, the price of plants at the nurseries, too, being within the reach of everyone.

There are yet many other varieties deserving a word in this list, which, however, is not meant to be an exhaustive treatise, but merely a rough sketch of the most desirable kinds. I must not, however, omit *R. leptoclada* (the flat-branched little Cypress), which is interesting indeed—its stiff, rather formal, spiral, dense, flat, purplish, branchlets giving the slow-growing little tree the appearance of having been artificially bronzed. With this and a passing mention of the graceful and Fern-like *R. filicoides*, I end my remarks.

*Maesgwynne, South Wales, in "Field."*

J. TAYLOR.

**Corchorus (Kerria) japonica.**—It is somewhat singular that the double-flowered variety of this plant should be so little grown. I saw a fine example of it in flower the other day, and few plants could be more showy seen against a red brick wall in April. It is a plant of the freest growth and simplest culture, and can be increased to any extent by means of cuttings, layers, or suckers. The latter, in fact, become troublesome in some positions. Once give the plant a footing in the garden, and it is not very easily got out again; yet it has been eradicated from most gardens, and one seldom sees it now unless in the garden of the parsonage or of the cottage. In warm sheltered places it does well in a bush form, like a stool of Raspberries, the flowering shoots being cut to the ground annually, and young ones brought up to succeed them. On a wall it may be carried to a great height; and perhaps is most effective when its yellow Marigold-like flowers are interspersed with the drooping bunches of the Blue Laburnum—if I may take the liberty of calling the *Wistaria sinensis* by such a common name.—F.

## NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Pyrus Malus spectabilis.**—We have recently observed some specimens of this in the Hentherside nurseries, worked so low that the branches laden with their brilliant buds nearly touch the ground. In this form this brilliant tree struck us as one of the best of all, for lawn or pleasare ground, when isolated or grouped on the turf.

**Remarkable Oaks.**—In Bagot's Park, Staffordshire, are some very fine Oaks. One, called "The King's Oak," is 120 feet high. Another, "The Beggar's Oak," has a girth of 44 feet at the height of one foot from the ground; and one of its branches has a circumference of 7 feet 1 inch at a distance of 15 feet from the trunk. A space of about 1,000 square feet is shaded by its branches.

**Chestnut Timber.**—In your notice of the Westminster Abbey examples of this timber, you should have stated that it is sweet or Spanish Chestnut, and consequently, though faster in growth than Oak, slower than Horse Chestnut, with which it might be confounded. At Preston Hall, near Maidstone, there is, or was at the time when Mr. Betts purchased the place, a barn roofed with Spanish Chestnut in a splendid state of preservation, and no doubt in many old places it is confounded with Oak.—W. P. A.

**Amelanchier canadensis.**—I have a dwarf variety of this shrub from one to four feet high, which, in spring, covers itself with white bloom, and in June, or early in July, is loaded with pleasant edible fruit. This I think would please you; I am quite sure it would make a sensation among your lovers of such things, and I should not be surprised if it were esteemed as a fruit-bearing shrub. My only trouble with it is, that the fruit, which is very sweet, is so attractive to birds that I get but little seed.—Geo. THURBER, New York.

**Wych Elms.**—In the gardens at Chiswick House are several large trees of this Elm, and, being in good soil and near the water, they are in remarkably vigorous health. A peculiar characteristic, however, pertaining to them is that they send down, from a height of about 30 feet, naturally pendent branches, issuing from the main ones, to near the ground. These drooping branches are about an inch or very little more in diameter, maintaining this slender proportion throughout their whole length. Have others observed anything like this?—W. F.

**Magnolia conspicua.**—As a spring-flowering hardy tree (this is unsurpassed; for during the latter half of March and the whole of April it is literally a mass of white blossom; seen in front of Pines or other deep green trees it has a grand effect. As an indoor plant, too, it is excellent; for the smallest piece, if rooted and potted and the wood well ripened, will flower from every eye. Plants grafted this spring, and well cared for, will produce from half a dozen to two dozen flowers next year in six-inch pots. Of such plants Messrs. Osborn have this year had many in flower, and their blooms were in no way inferior to those produced by established trees. When placed amongst Ferns and other green-foliaged plants, such charming little trees are extremely effective.—W.

## THE INDOOR GARDEN.

### DWARF PITCHER PLANT OF NEW HOLLAND.

(*CEPHALOTUS FOLLICULARIS*).

This forms a neat dwarf greenhouse plant, which grows from 2 to 3 inches in height, and has short spatulate leaves rising from the centre, and comparatively large oblong pitcher-shaped organs, lying on the soil in a somewhat circular outline around the leaves. The pitchers are green, tinged with purple or brown, with several fringed linear plates, extending lengthways on the outward surface of each, whilst the lower lip or mouth is formed with a regularly corrugated or ridged margin. In some varieties, the lid, projecting from the upper or back part, is prettily marked with reddish-crimson bars. It forms one of the most wonderful illustrations of singular vegetable structure and economy. It thrives well in a warm greenhouse temperature, planted in a mixture of chopped sphagnum and rough sandy peat, well drained; the principal precautions are to maintain a porous texture in the material in which it grows, admitting a free circulation of water, with a partially humid atmosphere in summer, but which should be gradually lessened in winter. A partially elevated bell-glass over the plant is often found conducive to its vigour, on account of its maintaining a more uniform temperature around it, and of its serving as a screen from the chilling effects of cold air or water upon the leafy appendages. The accompanying is an illustration of a fine specimen, grown by Messrs. E. G. Henderson.

### TOUCH-ME-NOT.

*IMPATIENS*.

This is a genus of plants popularly known as Touch-me-Not, a name given to them on account of the sudden manner in which the valves of the oblong capsule roll back, thus as it were shrinking from the touch. Amongst the numerous species of which the genus consists, many are exceedingly gay flowered, and have the additional recommendation of being free bloomers, and of easy culture; some of the kinds, too, deserve special attention, on account of their blooming during winter, when flowers are scarce. The different kinds of *Impatiens*, as a rule, do not require much pot room, but they must have the pots well drained. For soil, use good loam, leaf-mould, and thoroughly decomposed manure, mix the whole thoroughly, and whilst doing so, add about a fourth part of sharp sand. Some of the kinds make long straggling growths, but this must not be allowed; if the points of the young shoots are occasionally pinched out, it will induce them to make lateral shoots, and thus nice, handsome, compact plants will be formed. The majority of the kinds about to be enumerated produce the finest blooms, and also the greatest quantities of them, upon young plants of from one to two years of age; and as they grow sufficiently large in that time for most people's accommodation, they need not be kept longer. No apprehension need be entertained of losing the kinds by this system, if care is taken to provide young plants before the old ones are discarded; and as they strike readily from cuttings, this will not be found a difficult task. The annual kinds must, as a matter of course, be obtained every year from seed. Plants of *Impatiens* in active growth enjoy an abundant supply of water to the roots, and a moist atmosphere, but they do not like heavy syringing; indeed, it will be found most conducive to their health if the syringe is discarded altogether, and the necessary moisture provided by steaming, and by sprinkling the floor and stages with water. In whatever way it may be applied, moisture in the air is quite essential to their well-being, for a dry atmosphere is

sure to result in attacks of red spider, which will speedily rob them of their leaves; and flowers without foliage lose half their attractions.

*Impatiens Hookeri*.—The stems of this species are stout, pale green, and furnished with large leaves. The flowers are large, the petals being very broad, ground colour white, lined and streaked with reddish crimson, and being in full beauty during mid-winter, it is doubly valuable. This species has the reputation of being a shy bloomer, but if a succession of young plants is maintained, there will be little to complain of as to paucity of flowers. It requires the heat of an intermediate house, or cold stove, and may be brought into the conservatory when in bloom. It is a native of Ceylon.

*I. repens*.—Those who have a little stove Fernery will find this a lovely object, if planted in one of the pockets in the wall, or upon some jutting mass of rock-work. In such positions the stems will trail over and about the stones; these stems are clothed with small intensely dark green leaves, which form an admirable background for the display of its large brilliant yellow flowers, which are produced in great profusion from June to September. It is a native of the Indian Archipelago.

*I. Jerdoniæ*.—This is a dwarf, compact, East Indian plant, having stout, fleshy, somewhat gouty-looking dark brown stems, bright green leaves, and a crown of brilliant flowers, which continue in beauty for a long time during summer, producing a charming effect. Plants of this species require resting during winter; but they

must not be what is termed "dried off." Cultivators too frequently forget that their plants are in pots, and that, if the drying process is carried too far, the soil becomes perfectly baked through and through, and all the roots are killed, and the plants thus become much weakened instead of being simply rested.

*I. tricolor*.—This is a rare species, the flowers of which are extremely handsome. It comes from West Africa, where it is found at some distance up the Camarron Mountains, and any one having friends in that locality should get them to send them seeds of this *Impatiens*. It is a free-growing plant, producing a profusion of

rich white and plum-coloured flowers during the winter months.

*I. Walkeri*.—A somewhat slender-growing plant, and also an extremely rare one. It grows some 12 or 18 inches high. The leaves are medium-sized and brilliant green. The flowers are freely produced, and brilliant scarlet in colour. It blooms about the month of June, and continues a long time in full beauty. It is a native of Ceylon.

*I. flaccida*.—This is a somewhat spreading plant, and requires frequent pinching to render it handsome in shape. The leaves are bright green, some 3 or 4 inches long. The petals are broad, somewhat bilobed, forming a large rosy-purple spreading limb, with a long spur. It blooms during the early spring and summer months.

*I. flaccida alba*.—In general appearance and habit of growth this resembles the preceding, but its flowers are pure white, and as these are produced all through the winter months, it is a most desirable kind. I would, therefore, strongly urge the necessity of its cultivation. This and the preceding are natives of Ceylon.

*I. platypetala*.—At first sight this species would seem to be closely allied to *flaccida alba*, but by that as it may, it is a very desirable plant. It should be made to grow in a compact form; the flowers are large and of a warm rose colour. It blooms during early spring and summer, and sometimes it may be made to bloom in winter; there is a very handsome white variety of this plant, as well as of the previously named. It is a native of the East Indies.

*I. latifolia*.—This is no doubt nearly allied to *I. flaccida*, but is nevertheless very distinct. In the first place, it is erect in habit and much taller than *flaccida*, attaining a height of from 2 to 3 feet, or

New Holland Pitcher Plant.

even more. Its stems are swollen at the joints and furnished with abundance of large dark green leaves. The flowers are large, produced singly from the axils of the leaves, but there are plenty of them, and as they measure nearly 2 inches across, and are rosy purple in colour, they produce a fine effect. It blooms during the autumn and spring, and as it does not require so much heat as the other kinds, it will be found extremely useful for the decoration of the conservatory. It is a native of the mountains of Ceylon.—*Farmer.*

### JOHN STUART MILL AS A PLANT-LOVER.

Of the tens of thousands who are acquainted with the philosophical writings of Mr. Mill, there are probably few beyond the circle of his personal friends who are aware that he was also an author in a modest way on botanical subjects, and a keen searcher after wild plants. His short communications on botany were chiefly, if not entirely, published in a monthly magazine called the "Phytologist," edited from its commencement in 1841 by the late George Luxford till his death in 1854, and afterwards conducted by Mr. A. Irvine, of Chelsea, an intimate friend of Mr. Mill's, till its discontinuance in 1863. In the early numbers of this periodical especially, will be found frequent notes and short papers on the facts of plant-distribution, brought to light by Mr. Mill during his botanical rambles. His excursions were chiefly in the county of Surrey, and especially in the neighbourhood of Guildford and the beautiful vale of the Sittingbourne, where he had the satisfaction of being the first to notice several plants of interest, as *Polygonum dametorum*, *Isatis tinctoria*, and *Impatiens fulva*, an American species of Balsam, affording a very remarkable example of complete naturalisation in the Wey and other streams connected with the lower course of the Thames. Mr. Mill says he first observed this interloper in 1822, at Albury, a date which probably marks about the commencement of his botanical investigations, if not that of the first notice of the plant in this country. Mr. Mill's copious MS. lists of observations in Surrey were subsequently forwarded to the late Mr. Salmon, of Godalming, and have been since published with the large collection of facts made by that botanist in the "Flora of Surrey," printed under the auspices of the Holmesdale (Reigate) Natural History Club. Mr. Mill also contributed to the same scientific magazine some short notes on Hampshire botany, and is believed to have helped in the compilation of Mr. G. G. Mill's "Catalogue of the Plants of Great Marlow, Bucks." The mere recording of isolated facts of this kind of course affords no scope for any style in composition. It may, however, be thought worth while to reproduce here the concluding paragraph of a short article on "Spring Flowers in the South of Europe," as a sample of Mr. Mill's popular manner, as well for its own sake as a fine description of a matchless scene. He is describing the little mountain range of Albano, beloved by painters, and, after comparing its vernal flora with that in England, goes on:—

If we would ascend the highest member of the mountain group, the Monte Cavallo, we must make the circuit of the north flank of the mountains of Marino, on the edge of the Albano Lake, and Rocca di Tassa, a picturesque village in the hollow mountain side, from which we climb through woods abounding in *Galanthus nivalis* and *Corydalis cava*, to that summit which was the *axis* of Jupiter Latiaris, and to which the thirty Latian cities ascended in solemn procession to offer their annual sacrifice. The place is now occupied by a convent, under the wall of which I gathered *Ornithogalum nutans*, and from its neighbourhood I enjoyed a panoramic view, surely the most glorious, in its combination of natural beauty and grandeur of historical recollections, to be found anywhere on earth. The eye ranged from Terracina on one side to Veii on the other, and beyond Veii to the hills of Sutrium and Nepesinæ, once covered by the Ciminius forests, then deemed an impenetrable barrier between the interior of Etruria and Rome. Below my feet the Alban mountain, with all its forest-covered folds, and in one of them the dark blue lake of Nemi; that of Albano, I think, was invisible. To the north, in the dim distance, the Eternal City; to the west the eternal sea; for eastern boundary, the long line of Sabine mountains from Soracte, past Tibur, and away towards Praeneste. The range then passed behind the Alban group, but reappeared to the south-east as the mountain crescent of Cora and Pometia, enclosing between its horns the Pontine marshes, which lay spread out below as far as the sea line, extending east and west from Terracina in the Bay of Fondi, the Volscian Anxur, to the angle of the coast, where rises suddenly, between the marshes and the sea, the mountain promontory of Circeii, celebrated alike in history and in fable. Within the space visible from this one point the destinies of the human race were decided. It took the Romans nearly five hundred years to vanquish and incorporate the warlike tribes who inhabited that narrow tract; but, this being accomplished, two hundred more sufficed them to complete the conquest of the world.

During his frequent and latterly prolonged residence at Avignon, Mr. Mill, carrying on his botanical researches, had become very well acquainted with the vegetation of the district, and at the time of his death had collected a mass of notes and observations on the

subject. It is believed to have been his intention to have printed these as the foundation of a flora of Avignon. In the slight contribution to the literature of botany made by Mr. Mill, there is nothing which gives any inkling of the great intellectual powers of their writer. Though always clear and accurate, they are merely such notes as any working botanical collector is able to supply in abundance. Mainly content with the pursuits as an outdoor occupation, with such an amount of home-work as was necessary to determine the names and affinities of the species, Mr. Mill never penetrated deeply into the philosophy of botany, so as to take rank among those who have, like Herbert Spencer, advanced that science by original work either of experiment or generalisation, or have entered into the battle field where the great biological questions of the day are being fought over. The writer of this notice well remembers meeting, a few years since, the (at that time) parliamentary logician, with his trousers turned up out of the mud, and armed with a tin insignia of his craft, busily occupied in the search after a marsh-loving rarity in a typical spongy wood on the clay to the north of London. But, however followed, the investigation of nature cannot fail to influence the mind in the direction of a more just appreciation of the necessity of system in arrangement, and of the principles which must regulate all attempts to express notions of system in a classification. Traces of this are not difficult to find in Mr. Mill's writings. It may be safely stated that the chapters on classification in the "Logic" would not have taken the form they have, had not the writer been a naturalist as well as a logician. The views expressed so clearly in these chapters are chiefly founded on the actual needs experienced by the systematic botanist, and the argument is largely sustained by references to botanical systems and arrangements. Most botanists agree with Mr. Mill in his objections to Dr. Whewell's views of a natural classification by resemblance to "types" instead of in accordance with well selected characters; and indeed the whole of these chapters are well deserving the careful study of naturalists, notwithstanding that the wonderfully rapid progress in recent years of new ideas, lying at the very root of all the natural sciences, may be thought by some to give the whole argument, in spite of its logical excellence, a somewhat antiquated flavour.—*H. Trimen, in Examiner.*

## THE GARDEN IN THE HOUSE.

### MULTIPLE FLOWER VASES.

As with the first four rules in arithmetic, so with the various forms of flower-vases; they may conveniently be classified under the headings of simple and compound. By compound forms, I mean combinations of two or more receptacles for flowers in the same stand.

If you look over the collections of vases at the different glass shops in London and elsewhere, you cannot fail to remark how greatly the compound forms outnumber the simple forms, while of many of them it may truly be said that they are "wonderfully made." It has often been observed that different persons frequently regard the same object with very different views, and of nothing may this be more truly remarked than of a flower-vase. The buyer and the seller both regard it as a means to an end, but the "ends" of the two differ very widely. The object of the customer is to obtain something that will set his flowers off to advantage. The object of the manufacturer is to get as much money as possible out of the public; and to effect this he too often runs riot in beautiful forms and complicated combinations, which, however pleasing they may be to the eye of the critic, as works of art and ingenuity, are too often unsuitable for the purpose for which they were designed. Vases of this kind are unfortunately too numerous; and when asked to admire them, one feels more inclined to remark that they are fearfully as well as wonderfully made!

Although some of the compound forms are both pretty and useful, they all possess one drawback, which is, that, if the flowers at command happen to be unsuitable, or fail to be numerous enough to furnish it, the result is unsatisfactory.

These reflections induced me to think that it might be possible to have two or more forms of simple vases made, of such proportions that they might stand one upon another in different ways, and be built up to produce compound vases of various forms, to suit the quantity and character of the flowers to be arranged. With the view of testing the practicability of this notion, I have had a saucer and a trumpet-shaped vase made for me, and have tried them with flowers in many com-

binations. Though this is only a first attempt, and consequently must be open to many improvements, it has succeeded so well that it may be interesting to some of your readers if I explain the sizes of these two simple vases, and some of the ways in which combinations of them have been used.

The trumpet-shaped vase (fig. 1) is 10 inches high, and the diameter of both top and bottom of it are exactly 3 inches. The saucer (fig. 2) is 7 inches in diameter and 2 inches deep, and is furnished, both inside and outside, with a projecting rim of glass. By means of this rim, the trumpet vase is enabled to stand firmly either within the saucer (fig. 3), or beneath it (fig. 4).

In the rim of the foot of the trumpet vase three little nicks have been made at equal distances from each other, as shown at fig. 5. The object of this is to make a taller vase by putting one upon the other and fastening their feet together (fig. 6)

the base of the group, then the saucer should be placed as at fig. 12.

It sometimes happens that the foliage which one desires to use for the base of a group is not only small in quantity, but of a flimsy character; and in such cases the arrangement of the saucers (as at fig. 13) gives desirable support to the foliage. Where a large and tall group of flowers is required for the centre of a table, the combination shown at fig. 8, with the addition of a trumpet vase in the upper saucer, may be placed upon a base formed of three or of four supports, which consist each of one trumpet vase and two saucers (as shown at fig. 14). Where a tall pyramid of flowers is required as a centre-piece for a sideboard or a buffet, or for the middle of a table in a drawing-room, some such arrangement as that indicated at fig. 15 will be found very convenient.

The foregoing are but a few amongst the numerous combina-

by winding a piece of fine soft wire over the nicks and round the stems above and below the junction. A very useful form of vase for many kinds of flowers of light character is made by standing these united trumpet vases in the saucer (fig. 7). When the selection of flowers to be arranged is limited to those of a drooping character, such as Fuchsias, the combination shown at fig. 8 will prove most suitable for the purpose. Fig. 9 represents a useful combination where long Fern fronds or other good foliage is at command, to make the base of the arrangement broad in proportion to the height of the group. But when only short pieces of flower and foliage can be procured, it becomes necessary to form a base by putting three (fig. 10) or four of the saucers together, and placing another saucer on the top of them. If the base of the group is to be a pyramid of flowers, the saucers should be placed as in fig. 11. But if the supply of flowers is only sufficient to form a ring at

tions for which these two simple forms of flower-vase are available.

W. THOMSON.

**Gardening for Women.**—There is nothing better for wives and daughters, physically, than to have the care of a garden; a flower-pot, if nothing more. What is pleasanter than to spend a portion of every day in working among plants, watching their growth, and observing the opening of their flowers, from week to week, as the season advances? Then how much it adds to the enjoyment to know that your own hands have planted them and have pruned and trained them—this is a pleasure that requires neither great riches nor profound knowledge. The advantages which woman personally derives from stirring the soil and sniffing the morning air are freshness and beauty of cheek and brightness of eye, cheerfulness of temper, vigour of mind, and purity of heart.—*H. B. Stowe.*

## THE KITCHEN GARDEN.

### ASPARAGUS CULTURE.

MR. NIVEN'S METHOD OF CULTURE.

[Mr. Niven has so long cultivated Asparagus with such success at Drumcondra, that we have thought it well to give his method of culture.]

ANY time during the winter or spring choose any portion of the surface of your garden, with an open, south exposure; it matters not much what the soil may be on which the plantation is to be placed—provided the surface-water, in winter, does not stagnate on, or about it—but a soil of sandy quality is always to be preferred, where it can be obtained; but where not to be had, it is easy to add a few loads of sand in the surface preparation. Having fixed upon the space to be occupied, a layer of half-rotted leaves, or rotten hot-bed dung, may be spread over the whole, about 3 inches thick, to which might be added, where it can be obtained, a stratum of sea-weed. This, during the winter, should be slightly dug in to the surface, leaving the surface in narrow ridges, to receive the action of the weather. Or, it may be done immediately before planting in spring; the former time of preparation is, however, preferable. This process of surface management may be described under the following heads, viz.: Planting, summer treatment, winter treatment, forcing.

#### PLANTING.

About the end of March or beginning of April (or even in May, when the young heads are 6 or 8 inches high), choose a dry day, and have the ridged-up surface neatly levelled down, after which, slightly dig the ground over again, which will thoroughly mix the surface with the manure and sand first applied; then tread over the whole, regularly, with the feet, and proceed to mark off, with the measuring rod, the places for the intended lines, at 4 feet apart; studying to run them as nearly north and south as possible, marking the place of each line with the corner of a draw-hoe, as for Peas. This being done all over the plot, at the distances described, have a quantity of compost ready, such as one-third rotten leaves, or rotted dung, one-third fresh soil (a hazel-coloured sandy loam from the corner of any Grass-field is best), and one-third river or sea-sand. If this has been for some time previously prepared, so much the better. Along each drill or line lay a small ridge of the said materials, so that, when ready for planting, a section of the surface of the plot will appear thus:—

Choose, if possible, good strong two-year-old plants, a quantity of which may always be kept in a reserve seed-bed for successional plantations in any odd corner of the garden. As it is of essential importance that the roots should be as little exposed as possible during planting to a drying atmosphere, it may be best to proceed thus:—carefully lift the plants, and cover them over in the barrow, with a little sand; proceed to set them on the little ridge or saddle prepared for them, as a man sits upon horseback, at about 6 inches apart from each other, having a person to follow with a barrowful of sand, which, with the spade, he lays over the roots and crowns, about 1 inch thick, observing to tread successively both sides of each line as he proceeds, with one foot, to firm the sand to the plants, so as to secure them from the action of the air, until the process of planting is concluded, when a second and final covering of about 4 inches of the compost is to be put over the ridge or lines, which is to be firmly trod to the line of plants as before. A small portion of the original surface between may then be thrown up with the spade, right and left, pressing neatly between every two lines as you proceed, and the process of planting, which is exceedingly simple, is finished. A plantation so made, containing from 140 to about 200 square yards, and requiring from 700 to 1,000 plants, or so, would be sufficient to supply Asparagus during the season for any ordinary family—the expense of which, apart from the plants, (which might be about 2s. 6d. per hundred) would be a mere trifle, particularly where sand and leaves or rotten dung can easily be had. I may remark that I much prefer the single line method of culture to beds, chiefly on account of the greater

facility in the subsequent management, and because the plants derive more equal nutriment from the artificial surface that is gradually forming. The produce of two rows so treated I have found fully equal in quantity to any one bed with three lines besides being much superior in quality.

#### SUMMER TREATMENT.

This is an important matter in Asparagus culture. The plantation being finished, as has just been described, a good watering or two, should the weather be very dry, would, towards May, be advisable. In May, when the short Grass-mowing begins, a portion of it is to be brought to the Asparagus lines, and shaken in between, quite to the necks of the plants—say, so as to fill up the hollow spaces between nearly level, when a section of the plantation would, at this time, appear thus:—The object of this application, which must

be renewed about once every month during the summer, will be at once evident, namely—the retention of moisture, and the production of vegetable food, and the slight fermentation that accompanies the decomposition greatly accelerates the growth of the plant: besides ultimately a bed of the purest vegetable matter is formed, into which, on both sides, the succulent roots of the Asparagus plants run freely. In this way, from the proximity of the roots to the surface, the genial influences of solar heat, and due atmospheric action, are enjoyed by the plant, without the least danger of its ever suffering from drought, in consequence of the non-evaporating nature of the vegetable mulching or covering alluded to, which receives and retains, as a sponge, the greater portion of the moisture that falls upon it, whereas, in the common Asparagus bed, the surface during the dry part of the year is almost completely exposed to the action of the sun and air, and, during any continuance of dry weather, may be seen to crack or rend in every direction, to the destruction of the roots in very many instances. After the shoots have begun to come up, we immediately begin to look regularly and carefully after the thinning. When the plants have pushed two or more heads each, the weakest are regularly cut away, as the stronger heads appear; so that by the end of the first season, not more than two, or at most three shoots, are left to grow to maturity on each plant. Proper attention to the thinning of Asparagus, in the first instance, immediately after planting, during the first and second years and afterwards, also in cutting for use, is of essential importance towards the future welfare of the plant. In consequence of proper attention not being paid to the subject of cutting, arising either from carelessness of the consequences, or from over-anxiety on the part of the gardener to send to table a good dish, much evil ensues to the plantation; for, frequently, instead of leaving a sufficient supply of strong shoots regularly over the bed, they are all cut away, and the weakest left, the inevitable result of which is a supply of comparatively small buds for the crop of the year following.

#### WINTER TREATMENT.

In November, or, as soon as the tops of the Asparagus become yellow, the whole should be cut over, and the soil along the crown of the ridge or line cleared away a little with the hand, when about 4 inches of sea or river sand should be laid along over the line of plants—this chiefly for the purpose of providing against the depredations of slugs in spring, and the clean, free progress of the heads the following season. In the spaces between the lines, a few barrow-loads of rotten dung, leaves, or sea-weed may be laid, and the whole should be neatly levelled with a three-pronged fork, stirring up the surface between the lines very slightly, as the levelling of the fresh material proceeds. No further care will be required till spring, when, just as the first heads begin to appear, the whole may be slightly stirred on the surface, and over the lines a little of the sand raked off. The process of mulching with short Grass, or, instead of it, other vegetable or decomposing animal matter, is to be followed up, as already described, from year to year. The second year some of the thinnings may be fit for use, but by no means should any of the

strong heads be cut for that purpose, except where there are too many to one plant, as the patience and forbearance now exercised will be amply repaid by the produce next year, when the crop may be regularly cut for use. In gathering Asparagus, a habit prevails of cutting the heads a few inches below the surface; but for what useful purpose I am at a loss to conceive; inasmuch as the white or blanched part of the Grass is usually so hard and stringy as to be scarcely fit for use; whereas, by allowing the heads to grow the proper length above the surface, say about eight inches or so, they will not only still be compact, but the whole of the "Grass" will be tender and eatable.

#### FORCING ASPARAGUS.

Wherever the forcing of Asparagus is an object, a supply may be cheaply and readily obtained for the table, for at least six months of the year. With the view of making a fresh plantation every third or fourth year, according to the quantity required, a small stock of seedling plants should be kept ready for use when needed. In the seed-bed I prefer sowing rather thinly, on a light, well-prepared bed of fine earth, which will yield plants fit for transplanting the first year after sowing; but after two years this would be better still. A plantation, such as I have described, being formed every fourth year, a portion of the preceding one may be lifted for forcing every year, after the second comes into bearing; and so keep on with a regular rotation of sowing, planting, and forcing, upon a comparatively small surface of ground, which will be much improved by the alternate cropping and moving. Various methods of forcing are in practice. Perhaps no more simple or successful one is followed than that of placing the roots in the border of any early Vinery or Peach-house "at work;" where, by being placed closely together, the spaces between the roots filled up with fine mould, and covered about 2 inches over the crowns, the produce will be rapid and regular, in proportion as the house may be slowly or quickly forced. A succession may be kept up in this way where there exists several such forcing-houses, as it is only in the early stage of the forcing of such houses that Asparagus will succeed best when grown in them. In a similar way a good succession of Asparagus may be kept up from an exhausted tan-pit in which Pines have been grown the preceding season. Next to the above method, where houses do not exist, or where it may not be convenient so to occupy them, old Melon-frames answer equally well, worked by fresh linings of fermented dung, the old bed being well perforated below, to permit the heat to pass more regularly into it from the linings. Two or three light frames worked alternately in this way, observing to fill one as the other is fit for cutting, will afford a regular supply for any middling-sized family, about every second or third day. Asparagus will also do well on newly made-up beds; but great care must be taken to have the materials well fermented, and the bed properly sweetened previous to planting, else the roots may be seriously injured, if not quite destroyed, as no plant is more impatient of over-heat than Asparagus; on this account I would prefer forcing this vegetable in exhausted beds or pits, as the case might be. The more closely the surface of any bed can be packed with roots, the greater the produce will consequently be, provided that sufficient space is left for a little package of fine mould amongst them, which operation must be carefully done, finishing the whole by a covering over the crowns about 2 inches thick, and settling the whole in a day or so after, with a good watering, when the bed may be shut close up, until the heat begins to rise, and the heads make their appearance, when, for the sake of strengthening and giving them colour, a little air may be admitted, more or less, according to the state of the weather and the heat of the bed; as a simple criterion, the guard, or watch-stick, should never feel much beyond blood-heat. Of late years Asparagus has been forced to some extent in permanent beds, formed by side walls of brick-work, the sides and ends being pigeon-holed; between which walls fermented dung is put, and the beds on either side are forced. This method answers very well where a large command of materials and labour can be had; but upon the whole, I would greatly prefer the simple method of forcing just particularised, namely, an old Melon-bed, or in exhausted Pine pits.

#### CELERY AND PEAS.

THESE do well together thus:—Form 2 or 4-foot trenches at intervals of 4 or 6 feet apart, according to the plentifulness or otherwise of your ground; 2-foot trenches are for two rows of Celery, 4 feet for four rows. I prefer two only, at intervals of 4 feet. Mark out the spaces, then dung and dig the centre of the space between the trenches at least a spit deep; next dig out the trench to the depth of 2 feet, forming one-half of the 4-foot ridge with the earth; 6 inches of the richest manure should then be dug into the bottom of the trench, incorporating part of it with the soil and spreading at least 3 inches of neat manure along the bottom, leaving the surface pretty even and smooth and quite light. A second trench is then formed in the same manner. These two form an elevated ridge of mellow earth with the deeply stirred richly manured centre. As soon as the ridge is finished, sow a row of No Plus Ultra, Veitch's Perfection, William's King of the Marrows, or any of Laxton's last and best Peas along the middle of it. These do wonderfully well among all this mass of earth; and, as the light and air play upon them on all sides, they are mostly podded from base to summit, and continue long in bearing. Peas so placed are generally exceptionally clean and unusually prolific. A row of Lettuces may also be planted on each side of the Peas, and will soon come to perfection. The ridges should run nearly north and south; if east and west, the shade will prove too much for the Celery in the trenches, which I by no means intend to sacrifice for the Peas; on the contrary, the Peas are meant to be helpful to the Celery, by affording shelter and providing shade. The ridges should be made in March at the latest; the ground in the bottom of the trenches will then have time to sweeten and mellow before May and June, the time for planting early Celery. The Peas should also be a foot or two high by that time, and staked before planting. This will prevent any earth from falling on to the Celery in a young state. In gathering Peas or cutting Lettuces, a board or plank may be used, to prevent the sides of the trenches falling in. With these simple precautions the Peas will be helpful to the Celery and a clear gain to the cultivator. Before the earth is wanted for blanching, the Peas will be gone. And if, instead of shaving down the sides of the trenches, the crown of the ridges where the Peas grew is used for earthing up or blanching the Celery, the original level of the ground and a spit below it will soon be reached; and the second trench could be again manured and planted with a single or double line of Coleworts, Walcheren or other Broccoli, or autumn Cauliflowers. In this way the sides of the trench would be the last earth used in blanching, and the contracted area of the trench would help to draw the Celery up with tender crispness. I have not tried Mr. Simpson's paper collars, but intend to do so this season. Doubtless they will greatly facilitate the earthing up, especially in this bed system of culture. One reason why I got from four rows to two was the difficulty of getting the men or boys to keep the earth out of the hearts of the Celery in the earthing of it up. A clod in the eye of growth means a crooked, deformed stick, hardly fit for soup, and entirely unworthy of cheese or salad at taking up time. Crispness—almost as easily broken as a glass walking-stick—is the chief merit of good Celery. Among the best means of growing it thus are, a rich cool larder—a cellar never dry—partial shade, careful earthing up, and perfect blanching—all at once, after the desired size is reached.

D. T. FISU.

#### Virginian Poke or Pigeon-berry (*Phytolacca decandra*).

—This is a branching herbaceous plant, which is found not only in the United States of America, but also in the Azores, North Africa, and China. It throws up vigorous sprouts in spring as large as one's finger, clothed with undeveloped leaves. These shoots, cut when young, and cooked like Asparagus, are so nice that one who has once partaken of them is sure to wish for more. Who will try what cultivation will do for such a plant? Those who are disposed to undertake its cultivation should get roots of it this autumn. Divide them and set them in rich soil, 3 feet apart each way. That the plant has a medicinal reputation need not deter any one from eating it: whatever there may be active about the young shoots is entirely destroyed in the cooking. In Europe Poke is frequently grown in gardens for its showy character when in fruit.—*American Agriculturist*.

## WORK FOR THE WEEK. PRIVATE GARDENS.

**Conservatories.**—Azaleas and Camellias that have done flowering should be removed, repotted, and placed in warmer houses. Seed-vessels of *Rhododendrons*, Azaleas, and other plants should be pinched off, so as to throw increased vigour into the young growth, unless it be necessary to save seed, and then only a moderate quantity ought to be kept for that purpose. Clematises, Passion-flowers, Honeysuckles, Hibbertias, Mandevillas, Acacias, and similar plants now making growth freely, must not be allowed to receive any check from cold draughts or from scanty supplies of water; and the young wood should be judiciously thinned at an early stage, rather than severely pruned when further advanced. Tie in the young shoots gracefully and loosely, yet neatly, and never permit them to twine round each other. All free-growing plants must receive liberal waterings, no matter whether they are in pots or in borders; but at the same time let saturation in all cases be avoided. Remove such plants as have done blooming, and fill their places with flowering plants from pits or greenhouses. Plants that are stationary, such as climbers and subjects planted out, unless they are in flower, are greatly benefited by daily syringings, and if green-fly, red spider, or other insects present themselves, a little tobacco water, or water in which flowers of sulphur have been mixed may be efficaciously employed. Washing with a sponge or soft rag and water, in which some soft soap has been dissolved, is the most effectual remedy for scale.

**Greenhouse Plants.**—Put singly some of the best *Lobelias* into 4-inch pots for the decoration of the conservatory. *Celosias*, *Gomphrena globosa*, and the *Amarantus salicifolius*, should be shifted into larger pots than those they now occupy, as they increase in size; keep them in a moderately warm temperature and near the glass. Place plants of *Astilbe japonica*, for late blooming, at the base of walls facing the north. Stake *Calceolarias* and *Pelargoniums* if necessary, but if they can be grown stably enough to support themselves all the better; weak manure water is beneficial to them when coming into flower. Cut over *Cinerarias* and plant the roots in a rich border in the reserve garden, where they will soon emit shoots, that should be taken off and potted singly for use next year. Tulips, Hyacinths, Crocuses, Lily of the Valley, *Astilbe japonica*, and other plants that were forced into flower early in the season, should now be consigned to some shady border. Apply a mulching of loam and decayed manure in equal proportions to Lilies in pots, and, with the exception of such as are required for early flowering, keep them either out-of-doors or in cool frames. Shake unstarted *Daturas* out of their pots, repot them in good loam, leaf-mould, and some decayed manure, and place them in a warm pit for a time. Fuchsias, both hybrids and species, wintered under stages in greenhouses should be pruned, shaken out of the pots they now occupy, potted afresh, and kept in cool pits; they will come in usefully after early blooming ones. Keep early spring struck cuttings near the glass in warm houses, shifting them when necessary. Keep *Coleuses* near the light in an intermediate temperature, and repot and pinch in their shoots as may seem necessary. Seedlings and offsets of *Cyperus alternifolius* make fine table ornaments; good loam and leaf-mould, moderate heat, and plenty of water, suit them well, and 4-inch pots are quite large enough for them. Place old plants of *Campanula pyramidalis* out-of-doors, and keep seedlings of the same in a fair growing condition under glass. Keep up a succession of *Mignonette* in pots; a situation at the base of a wall shaded from the mid-day sun, and well sheltered, suits well established plants perfectly; but in the case of seed pots, and for some time after the young plants have made their appearance, they should be kept under glass. Give some manure water to *Kalosanthes*, and keep them in cool airy positions near the glass. Retain some specimens of *Humea elegans* for conservatory decoration. Place pots of *Tropeolum tricolorum* and others of that class under greenhouse stages, where they can be kept cool and dry. Hydrangeas for early blooming require a little extra heat, and such shoots as have no flower truss on them should be cut off and used for cuttings. Shift *Statice* as they require it. Introduce some plants of *Vallota purpurea* into heat, in order to induce early flowering. Plants of *Sericographis Ghiesbreghtii*, and *Ianthemum miniatum* should be cut back and placed in a warm moist temperature. *Solanums*, *Ferduandas*, *Abutilons*, and other subtropical plants, from which the spring stock of cuttings has been procured, may now be placed in sheltered positions out-of-doors.

**Kitchen Garden.**—Crops generally, in this department, are backward this season. Early Peas are, however, now in flower. Cabbages have formed nice hearts, and early-planted Cos Lettuces are in good usable condition. A piece of matting tied around the most advanced of the Lettuces makes them heart better. Plant out successions of Lettuces as required, and sow a few seeds of the same on

wall borders. Sow *Canliflowers* for late autumn use at once; a few of the strongest of those raised under hand-lights will now be fit for use. Thin Parsnips to 9 inches or 10 inches apart in the rows; and thin Beet and Carrots a little, but not finally. A few Early Horn Carrots should be sown occasionally for drawing in a young state. Weed and thin Onions, and use the hoe freely between the rows. Plant out some of the earliest Brussels Sprouts, and sow some Savoys for late use. Prepare trenches for early Celery, about 4 feet or 5 feet apart, and transplant succession plants out of frames into beds or patches in a warm border. Sow a few Cardoons in rows where they are to remain. Thin plantations of Spinach, sow some for succession; and, where winter Spinach is exhausted, manure and dig the ground for Cabbage, Brussels Sprouts, Peas, &c. Sow Turnips in quantities according to the demand, and thin the later sowings. Small Salads should be sown weekly, and Radishes fortnightly. Remove flower-spikes from Rhubarb, unless they are required for seed. Sow some seeds of green Curled Endive for an early crop. Make a small sowing of Rampion on a rich shady border. Plant out Vegetable Marrows on light hotbeds, under hand-lights for a time, until the roots become established, and prepare pits in open quarters for others. If Tomatoes have been well hardened off, they may be planted at the base of walls facing the south; and, in the warmer portions of the kingdom, a warm border, or well-sheltered quarter of the garden, may be wholly devoted to their growth. Sow some French Beans for succession; and, if sufficiently advanced, earth up Potatoes. Those in frames should have free ventilation, and be sparingly watered between the rows.

**Flower Garden.**—Flower beds previously prepared must now be filled. Edgings of *Sedums*, *Sempervivums*, *Echeverias*, variegated Thyme, *Polemonium caeruleum variegatum*, *Arabis albida* and *lucida variegata*, *Alyssum saxatile variegata*, *Ajuga reptans rubra*, variegated *Aubrietias*, *Ivies*, *Euonymuses*, *Loniceras*, variegated forms of *Poa trivialis* and *Dactylis glomerata*, *Dell's crimson Beet*, *Gnaphalium*, *Stachys*, the variegated *Cress* and *Meadow Sweet*, *Cerastiums*, *Viola cornuta* and others, *Gazanias*, *Santolinas*, *Salvia argentea*, *Saponaria calabrica*, and many other plants, will doubtless long since have been planted, so as not to delay the planting out of the more tender plants. *Pelargoniums* of different sorts should be kept out of doors, under the shade of trees or under canvas screens, until finally planted out, which should be done in the warmest positions, first using the hardiest of the plants. *Pelargoniums*, *Verbenas*, *Calceolarias*, *Centaureas*, *Cineraria maritima*, *Fuchsias* (if not started in heat), *Gazanias*, *Lobelias*, dwarf *Nasturtiums*, &c., should be amongst the first planted out; *Heliotropes*, *Perilla*, &c., about the middle lot; and *Iresines*, *Coleuses*, *Alternantheras*, *Amarantuses* of the finer kinds, *Musas*, and other subtropical plants, should be left until the last—indeed, it is only a risk consigning these to the open ground sooner than the 1st of June. Stocks and Asters should be planted out at once, and, if a sowing be made on a border out of doors now, good late-flowering plants will be obtained therefrom. *Tagetes* and French and African *Marigolds* may likewise be finally planted; the former makes a good substitute for the yellow *Calceolaria* on a dry soil, and the latter do well in shady borders or under comparatively open trees. Everlastings of different sorts may now be turned out; if they have been pricked out at the base of a wall, there will be but little fear of them; but, if nursed in pits or frames, they will require more care. English *Marigolds* make good plants for growing under trees; and, as they are self-producing, they spring up everywhere where plants of the same kind previously existed. *Mangles* variegated *Pelargonium* planted here and there in a bed of *Verbena venosa* makes a fine appearance. A carpet of blue *Lobelia* studded with good specimens of *Polemonium caeruleum variegatum*, or *Centaurea ragusina*, in pots and plunged in the soil, is also very effective; and a belting of the crimson Beet or *Coleus Verschaffeltii* alongside one of *Centaurea ragusina* or other white-leaved plant, makes an excellent contrast. Specimens of *Cycas revoluta* in pots, and plunged in the centre of round beds, and surrounded by dwarf and bright-coloured plants, are very attractive. The variegated and green-leaved *Dracaenas*, *Ficuses*, *Monstera*s, *Palms* of different kinds, *Ferns*, particularly *Asplenium Nidus avis*, *Acacia Lophantha*, *Castor-oil plants*, *Arabis*, *Wigandias*, *Ferduandas*, *Musas*, and others, make fine ornaments when employed as centres to beds, or as individual specimens plunged on lawns. In small beds a most interesting effect is produced by plunging in a belt near the edge some pots or pans, previously made up of dwarf plants, such as *Sempervivums*, *Saxifrages*, *Alternantheras*, &c., set as it were in a carpet of *Selaginella Kraussiana*. For back lines *Dahlias*, *Hollyhocks*, tall *Ageratums*, *Salvia splendens* and *patens*, *Cannas*, *Acer Negundo variegatum*, and *Rhus glabra laciniata*, are very suitable. For a carpet under such plants as *Fuchsias*, the variegated *Acer Negundo*, and other plants that cannot be planted so thickly as to cover the ground without injuring one another, the following

may be used, viz:—*Ajuga reptans rubra* and *variegata*, *Lamium maculatum aurum* and *album*, *Pyrethrum Tehiatchewi*, *Veronica repens*, *alpina*, and *incana*, *Viola cornuta*, *Mimulus*, *Sedum glaucum*, *oppositifolium*, *acre*, *album*, and *elegantis*; *Lysimachia nummularia*, and *L. n. aurea*, &c.

## SOCIETIES, EXHIBITIONS, &c.

### CRYSTAL PALACE.

MAY 17TH.

THIS, as usual, was a large and fine exhibition, and it was arranged with much taste and skill. Occurring, as it did, immediately after the great show at Regent's Park, it consisted largely of plants shown there. Full descriptions of many of the subjects exhibited on this occasion are, therefore, unnecessary.

**Stove and Greenhouse Plants.**—Here, as at Regent's Park, Mr. Baines was first, in the class of twelve plants, with magnificent specimens; and the second prize group came from Mr. Chapman; Mr. Morse, Epsom, and Mr. G. Wheeler were the other competitors in this class. In the nurserymen's class, Messrs. Jackson & Son, Kingston, were first with a splendid collection, in which was a plant of *Imantophyllum minutum*, bearing twenty good flower-spikes; also a large plant of *Acrophyllum venosum*. Mr. Wm. Cutbush, Barnet, who was second, had a fine medium-sized plant of *Gompholobium polymorphum splendens*. In the amateurs' class for nine plants, Mr. B. Peed, St. John's Lodge, Lower Norwood, was first. Amongst his plants were fine examples of *Epacris miniata splendens* and *Stephanotis floribunda*. In Mr. Ward's group, which was second, was, perhaps, the finest plant of *Statice profusa* ever shown; it was some 5 feet through, and one mass of flowers. For six fine-foliaged plants, Mr. Baines was first, with *Cordyline indivisa*, *Dasyliion acrostichum*, a fine specimen of *Theophrasta imperialis*, *Croton pictum*, a magnificent example of *Sarracenia flava*, with very large and perfect pitchers, and another species of *Sarracenia* with as tall-growing leaves as the other, but with much narrower pitchers. Mr. B. S. Williams, Upper Holloway, was second, with a grand plant of *Cycas revoluta*, a perfect specimen of *Cordyline indivisa*, *Croton pictum*, *Chamaerops humilis*, *Gleichenia Spluncea*, and *Dasyliion plumosum*. Mr. W. Foreman, Carlton House, Herne Hill, was third, with some fine *Marantas*, *Cupania filicifolia*, &c. Several groups of stove and greenhouse plants were arranged for effect, and in this class Mr. Foreman was also first; Mr. J. Fewell, Broad Green Lodge, Croydon, was second; Mr. Peed third, and Mr. Morse fourth.

**Cape Heaths.**—Of these there were many groups, in all respects excellent; but that from Messrs. Jackson & Son, which was unusually fine, obtained the first prize. It consisted of *Erica depressa* and *E. depressa multiflora*, both about three and a half feet through, and of other equally large and effective plants. Mr. Ward, Mr. Peed, and Mr. J. Wheeler were the other successful competitors.

**Azaleas.**—Of these the following are some of the best kinds, viz:—*Reine des Roses*, bright rose; *Madame A. Verschaffel*, violet rose; *Louise Margottin*, white striped; *Flag of Truce*, white; *Reine des Fleurs*, salmon and white; *Hooibrinki*, purple; *William Bull*, shaded red; and *Marie Vervaene*, white, striped with rose. The successful competitors were Messrs. Turner, Lane & Son, Jackson & Son, Dobson & Son, Wheeler, Peed, Herrington, Roach, and Chapman.

**Orchids.**—Of these some excellent plants were shown. Mr. Ward was first in the class of fifteen plants, with a superb example of *Phalænopsis grandiflora*, *Odontoglossum Alexandra*, a splendid *Dendrobium Devonianum*, a good *Odontoglossum Phalaenopsis*, a large plant of *Oncidium ampliatum*, &c. Mr. G. Wheeler, Regent's Park, was second. In the nurserymen's class, Mr. B. S. Williams was first, with a group containing a specimen of *Cypripedium candidum* furnished with nineteen flowers, a good *Acerides Fieldingii* with two spikes, *Saccolabium retusum* with four flower-spikes, &c. Messrs. Jackson & Son, who had the second prize, exhibited splendid specimens of *Dendrobium infundibulum*, and others. In the class of six plants, Mr. J. Wheeler was first, and Mr. Peed second.

**Pelargoniums.**—Of these some good examples were exhibited, especially from Mr. Ward, of Leyton, whose finely-flowered specimens elicited universal admiration. Messrs. Dobson & Sons, and also Mr. James exhibited good groups of show and fancy kinds. Zonal and tricolor varieties were exhibited in excellent condition by Messrs. Carter & Co., and by Messrs. Downie, Laird, & Laing.

**Roses.**—These were large and beautifully flowered, the blooms being of good size, form, and colour. In the class of ten distinct sorts Mr. Turner was first with splendid specimens of *Victor Verdier*, *Madame Victor Verdier*, *Juno* (fine), *Celine Forestier*, *Charles Lawson*, *Souvenir de la Malmaison*, *Paul Verdier*, *Vicomte Verdier*, *Souvenir d'un Ami*, and *Maréchal Vaillant*. The same exhibitor was also first in the class of twenty Roses. Messrs. Paul & Son, Ellis, and James were the other successful exhibitors. Mr. J. Skinner, Westerham Hill, Kent, furnished a box of cut blooms of *Maréchal Niel*, each of which was from 6 inches to 7 inches across; Messrs. Lane had also interesting exhibitions of Roses.

**Clematises.**—Of these Mr. Noble exhibited a fine collection of early flowering sorts, and also several new seedlings of his own raising, to which we have already alluded. The same exhibitor took the first prize

for six Clematises. Messrs. Downie, Laird, & Laing exhibited a fine pure white double-flowered sort named *Lucie Lemoine*.

**Miscellaneous Subjects.**—A collection of cut flowers of Tulips was contributed by Mr. Turner, and a group of fine herbaceous *Calcolarias* by Messrs. Dobson and Sons. Messrs. Downie, Laird, and Laing supplied an extensive group of plants, in which were a fine plant of *Cocos Weddelliana*, a nice specimen of *Dieffenbachia Bowmannii*, a pretty plant of *Ficus dealbata*, the graceful *Pandanus ornatus*, and a basketful of their excellent new bedding Pansy, called *Blue King*. Mr. B. S. Williams exhibited a group of Orchids, and other plants, including *Colax jugosus*, *Cattleya Mendellii*, *Maranta Makoyana*, *Draena Fraseri* and *splendida*, some fine Ferns, Palms, &c. A group of Palms, Ferns, and other stove and greenhouse plants was shown by Mr. J. Ley, Croydon; it contained a fine plant of *Todea superba*, crested *Gymnogrammus*, a good plant of *Dieffenbachia Bausii*, *Draena regina*, and others. Messrs. Dick Radeliffe and Co. showed charming specimens of Fern and other plant-cases; and Mr. T. S. Ware, Tottenham, had a group of herbaceous plants. Messrs. J. Carter and Co. contributed a varied group of miscellaneous subjects, including *Ancetochilus Orgosii*, *Lowii*, and others; *Davallia alpina*, *Peperoma reseda-folium*, *Cephalotus foliularis*, *Selaginella lepidophylla*, *Caladium argyritis*, *Croton irregularis*, *Maranta Sieboldii*, Japanese Maples, *Echeveria pulverulenta*, and several others. *Rhododendron fragrantissimum* was shown by Mr. Cottrell. Cut flowers of Pansies were shown in great variety by Messrs. Downie, Laird, and Laing, by Mr. James, and Mr. Ware. Mr. Wm. Thomson, of Penge, exhibited a dinner table set with glasses on the multiple principle, the effect of which was excellent; and Miss Hassard furnished another table prettily decorated. The same lady, and Miss Thomson likewise, contributed several coat-flowers and bouquets.

### ROYAL HORTICULTURAL SOCIETY.

MAY 21ST.

THIS, although not one of the large summer shows, was nevertheless, in some respects, equally interesting. Its chief features were Heaths, fine-foliaged plants, Pelargoniums, and contributions of a miscellaneous character.

**Heaths.**—These were remarkably fine, the specimens being large and well-flowered. Messrs. Jackson & Sons, Kingston, were first, with a splendid group of nine plants; and Mr. Ward, of Leyton, second, with equally good, though smaller plants. In other classes, Mr. Ward and Mr. J. Wheeler, Stamford Hill, and others, occupied prominent positions.

**Pelargoniums.**—These were wonderfully large and well-flowered. Mr. Ward was first in two classes for show kinds, the varieties being *Maid of Honour*, mauve, upper petals dark; *Patroness*, white, upper petals spotted with dark crimson; *Pericles*, bluish; *Rob Roy*, fine; *Warrior*, a splendid scarlet velvety flower; *Royal Albert*, *Atalanta*, *Alabama*, and others. In the class of fancy Pelargoniums, Mr. James, Isleworth, was first, with half-a-dozen well-bloomed plants, consisting of *Helen Beck*, *Princess Teak*, *Aene*, *Juliet*, *Lucy*, and *Fanny Gair*. Mr. Weir, The Elms, Hampstead, also showed some good plants. Messrs. E. G. Henderson & Sons had some fine zonals, and Mr. Wm. Paul fine examples of tricolor and bicolor kinds.

**Fine-foliaged Plants.**—In the class for nine kinds, Mr. Baines was first, with admirable plants of *Croton pictum* and *variegatum*, *Theophrasta imperialis*, *Dasyliion acrostichum*, *Rhopala corcovadensis*, *Cordyline indivisa*, *Yucca aloifolia variegata*, and two splendid specimens of *Sarracenia*. Mr. Cole, of Ealing; and Mr. Foreman, Carlton House, Streatham, exhibited two good groups, for which they obtained prizes. In the nurserymen's class of nine plants, Mr. B. S. Williams was first, with excellent specimens of *Gleichenia Spluncea*, *Croton pictum*, *C. variegatum*, *Dasyliion plumosum*, *Yucca aloifolia variegata*, *Chamaerops humilis*, *Cycas revoluta*, and *Cordyline indivisa*. Mr. J. Burley, Hereford Road, Bayswater, also showed some good plants. For twenty fine-foliaged plants in pots not exceeding 12 inches in diameter, Mr. Bull, Chelsea, was first, with a superb collection, consisting of *Zalacca Wagnerii*, a curious Palm, with leaves 11 feet long; *Macrozamia spiralis curvata*, *Encephalartos regalis*, *E. cyathifolius*, *E. villosus*; *Cycas revoluta*; a splendid plant with fourteen leaves of *Carex recurvata variegata*, and *C. striata*; a nice specimen of *Phormium Colensoi variegatum*, a large plant of *Todea superba*, a good plant of *Draena excelsa*, and others. Mr. B. S. Williams was second, with a specimen of the graceful-looking *Cocos Weddelliana*, some of the leaves of which were 4 feet in length; good specimens of *Pandanus Veitchii*, *Draena Cheloni* and *Guiltovlei*, *Spherozyne latifolia*, *Beaucarnea recurvata*, and others. Messrs. W. Rol-lisson & Sons, Tooting, were third; conspicuous among their plants were *Croton interruptum*, variegated *Ananassa*, *Draena porphyrophylla*, *Pandanus Vandermeerschii* and *ornatus*, and *Alocasia Lowii*.

**Orchids.**—An extremely fine group of these was contributed by Mr. W. Denning, gardener to Lord Londesborough; it contained two plants of *Masdevallia Dennisonii*, one of which had six and the other eleven brilliantly coloured flowers; also *M. Harryana*, a large *Utricularia montana*, with a profusion of white flowers; a specimen of *Odontoglossum citrosimum roscum*, with a fine closely-set flower-spike of pale rosy-lilac blooms; and a prettily-flowered specimen of *O. niveum majus*, and one of the lovely white *O. pulchellum*. In addition to these, the same exhibitor furnished a medium-sized plant of *Cattleya Mossie* with seven flower-spikes, *C. Wagnerii* with two beautiful white flowers, *C. Keinekiana*, *C. Warneri*; *Dendrobium Schroderi*, *crystallinum*, and *Devonianum*; well-flowered plants of *Acerides virens* and *Lobbi*, the white-flowered

*Vanda Denisonii*, the orange-red coloured *Lælia cinnabarina*, and a specimen of *Oncidium altissimum* with eight flower-spikes. Messrs. Osborn and Sons sent a pretty *Bletia hyacinthoides*; and from Mr. Richards, of Gunnersbury Park, came an admirable group of Orchids, comprising a dozen varieties of *Odontoglossum Alexandræ*, *O. niveum*, a superb variety of *Dendrobium nobile*, some pretty *Masdevallias*, and well-flowered plants of *Camarotis purpurea*. Messrs. Veitch and Sons sent a plant of *Odontoglossum vexillarium* with four flower-spikes with fully-expanded blooms, well-flowered plants of *Cypripedium niveum* and *lavigatum*, *Lælia anceps*, *Dendrobium infundibulum*, *Oncidium bifolium*, *concolor*, and others. A specimen of *Oncidium Kraueri* was sent by Mr. Wood, Stamford Hill; and *Orchis fusca* and *Ophrys anthropophora* by Mr. Ware. Of *Masdevallia Harryana*, a fine specimen with six flowers was contributed by Mr. J. Mills, Rendlesham Hall, Suffolk.

**Hardy Plants.**—Of herbaceous plants in pots, Mr. R. Parker, Tooting, sent an admirable group, for which a first prize was awarded. It contained the pretty *Iberis coræeifolia*, *Phlox frondosa*, the variegated variety of *Heimerocallis Kwanso*, *Funkia elegans viridis variegata*, *Iris spectabilis*, *Centaurea montana*, *Alyseton montanum*, *Trollius napellifolius*, *Aubrietia purpurea grandiflora*, and variegated Lily of the Valley. Mr. T. S. Ware was second, with another fine group; in addition to which he showed another group of other herbaceous plants, containing the yellow Columbine (*Aquilegia aurea*), *Libertia ixioides fol. variegata*, the scarlet-flowered *Anisanthus splendens*, *Tulipa Breniana*, and others. From John Luscombe, Esq., Combe Royal, South Devon, came a collection of remarkably fine cut flowers of *Rhododendrons*, gathered from plants growing in the open air. For these a cultural commendation was awarded, and the same exhibitor received a similar mark of distinction for shoots of two kinds of *Embothrium*, laden with red flowers, taken from trees 18 feet high and growing in the open air, and for shoots of *Ilex latifolia* in fruit and flower, and shoots of *Eucalyptus montana* taken from a tree growing in the open air and having a trunk some 6 feet in circumference. Of cut flowers of hardy trees and shrubs, some fine collections were shown. Mr. W. Earley, The Gardens, Valentines, Hford, was first, with a most extensive collection, including *Rhododendrons* of different sorts, Lilaes, Chestnuts, *Clematis montana*, Guelder Roses, double-flowered Cherries, Ghent Azaleas, *Skimmia japonica*, different sorts of Broom, *Cydonia japonica*, *Magnolias*, Hawthorns, *Jasminums*, *Laurustinus*, *Spiræa prunifolia*, *Berberis*, hardy Daphnes, Bird Cherry, *Menziesia polifolia*, *Loniceras*, *Cercis Siliquastrum*, and several other commoner subjects. Mr. J. George, Putney Heath, was second, with a group of somewhat similar, though less numerous, flowers. Miss F. M. Barr, Mr. R. P. Barr, and Mr. T. J. Ware showed groups of named *Narcissi*. English and fancy Pansy flowers were sent by Mr. Ware.

**The Davis Memorial Competition.**—To Mr. Baines' excellent exhibition set up for the Davis prizes we have elsewhere alluded. Two years ago a seal was affixed around the necks of eight plants belonging to each of the intending competitors, the plants being then in 6-inch pots. Of these only the plants grown by Mr. Baines were exhibited; but they were models of skilful cultivation. Their dimensions were as follows, viz.:—*Aphelaxis macrantha rosea*, 3 feet 6 inches through, and 2 feet high (a beautiful plant); *Epacris Eclipse*, 4 feet 3 inches through, and 3 feet 3 inches high (splendidly flowered); *Boronia pinnata*, 4 feet 6 inches through, and 3 feet 3 inches high (a neat and graceful plant); *Ixora coccinea*, 4 feet 10 inches through, and 3 feet 6 inches high (a superbly flowered specimen); *Hedera tulipifera*, 3 feet 3 inches through, and 2 feet 10 inches high (flowers finely coloured); *Dipladenia amabilis*, 3 feet 6 inches through, and 3 feet high (well flowered, fine); *Bougainvillea glabra*, 3 feet 6 inches through, and 3 feet 6 inches high (a very good plant); *Clerodendron Balfourii*, 5 feet through, and 4 feet high (extremely fine).

**Miscellaneous Plants.**—From Messrs. Osborn & Sons, Fulham, came a fine group of miscellaneous plants, in which was a pretty plant of the purple-flowered *Bletia hyacinthina*; also a well-flowered plant of *Oncidium sphacelatum*. Some fine plants of *Anthurium Scherzerianum*, a graceful little plant of *Dæmonorops fissus*, the pretty tricolor *Fuchsia Sunray* and several other flowering and fine-leaved plants. Messrs. Dobson & Sons supplied a group of herbaceous *Calecolarias*, with finely formed and well marked flowers. Several cut flowers of *Roses* were supplied by Messrs. Paul & Son, and a collection of the same, together with cut blooms of *Rhododendrons* and *Zonal Pelargoniums*, were supplied by Mr. Wm. Paul, Waltham Cross. Messrs. Veitch and Sons, Chelsea, sent a fine group of Japanese Maples, including the dark crimson, variegated, and green-leaved kinds, and also an extremely fine collection of Azaleas, the flowers of which were large, and of good form and colour. Messrs. Lane & Sons also exhibited a collection of Azaleas, and Mr. R. Dean, Ealing, sent examples of a pretty double Stock called *Violette*, and cut flowers of his double-flowered pyramidal one called *Maive Queen*; Messrs. E. G. Henderson & Son furnished some very fine striped seedling *Pelamias*. *Rhododendrons* in pots were shown by Mr. Rowe, Roehampton, and Mr. G. Wheeler, and a magnificent specimen of *Cycas revoluta* in a medium-sized pot was shown by Mr. T. Woodford, Eastwell Park, Ashford, Kent. This plant was some 8 feet in diameter, and densely furnished with healthy foliage, and in the centre was a fine head of inflorescence; a cultural commendation was given for it.

**Fruit and Vegetables.**—Some finely ripened fruit of Little Heath Melon was contributed by Mr. Munro, of Potter's Bar; this variety received a certificate last year, and this season it promises to sustain the good character it then received. Mr. Henderson, Thoresby Park, Notts, sent samples of Royal Ascot Melon, that were highly thought of. A dish of Pears and another of Apples were exhibited in

an excellent state of preservation. Black Hamburgh Grapes, well coloured and ripened, were sent by Mr. Marcham, of Wentworth; and a fine bundle of Asparagus was contributed by Mr. T. Bray, Nynehead Court. Of Northampton Hero Broccoli, Messrs. Watts & Sons sent fine samples, and Mr. R. Dean furnished specimens of Knight's Protecting Broccoli. Large bunches of Banana fruits, and baskets of fruit of *Passiflora quadrangularis* and the Chinese Loquat, and canes of the Sugar Cane, all imported from Madeira, were exhibited by S. Mart & Co., 130, Oxford Street.

**First-class Certificates.**—These were awarded to the following:—  
Tea-scented Rose Madame George Schwartz (Lane), a most excellent purplish red Rose, of strong growth, and powerfully tea-scented.  
*Gloxinia* Mr. Haines (Veitch), a crimson-flowered sort, of great merit, with a violet-shaded throat.  
*Gloxinia* Prince Leopold (Veitch), somewhat like the former.  
*Oncidium concolor* (Veitch), a beautiful canary-yellow coloured flower.  
*Zonal Pelargonium* Scarlet Gem (Smith), the flowers are of fine form and of an intense scarlet colour, with a conspicuous white eye.  
*Clematis* Charles Noble (Noble), a splendid large-flowered dark violet-coloured early-flowering sort.  
*Clematis* Elaine (Noble), a double-flowered, blue, early-flowering kind.  
*Clematis* Mrs. Cholmondeley (Noble), a very large, pale, lilac-bloomed sort.  
*Clematis* May Queen (Noble), a finely-formed, delicate blush flower.  
*Clematis* Undine (Noble), a dark, purplish-violet, double-flowered sort.  
*Pelargonium* Northern Star (E. G. Henderson), a fine golden bronze, with a very broad zone.  
*Pelargonium* Admiral Inglefield (E. G. Henderson), a golden bronze, with a very broad, dark, and distinct zone.  
*Azalea indica*, var. *Madame Paul* Deschryver (Veitch), a double-flowered carmine flower of great promise.

## OBITUARY.

It is with much regret that we have to announce the death of Mr. Mitchell, of Pitdown, which took place last Saturday night. It appears that he was suddenly seized with a fit of apoplexy on Saturday afternoon, and, although medical aid was at once called in, and every remedial means applied that medical skill could suggest, he died in the course of a few hours. Mr. Mitchell was well known, not only in Sussex, but throughout England, as a most successful Rose grower. There have been few flower shows which he has not attended and at which he has not appeared among the chief prize takers. Being much respected by all who knew him, he leaves a wide circle to lament his loss.

## COVENT GARDEN MARKET.

MAY 23RD.

HOME-GROWN vegetables of excellent quality are plentiful, including spring Cauliflowers obtained from under hand-lights. Cherries, Apricots, Strawberries, Lettices, Turnips, Artichokes, Carrots, and other produce imported from the Continent and Channel Islands, have also been abundant, and of good quality.

**Prices of Fruits.**—Apples, per doz., 2s. to 3s.; Apricots, 2s. to 3s. per doz.; Cochs, per lb., 2s. to 2s. 6d.; Cherries, per box, 3s. 6d. to 6s.; Gooseberries, per quart, 8d. to 1s.; Grapes, both house, per lb., 8s. to 15s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 6s. to 12s.; Peaches, per doz., 1s. to 30s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 8s. to 12s.; Strawberries, per oz., 9d. to 1s. 6d.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 3s. to 6s.; French, 4s. to 12s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, each, 6d. to 9d.; Cabbage, per doz., 1s. 6d. to 2s.; Carrots, per bunch, young, 1s. 6d., old do., 8d.; Cauliflower, spring, per doz., 8s. to 12s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 6d. to 2s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettices, per doz., 1s. to 2s.; Mushrooms, per pot, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 8s. to 12s.; button, per quart, 1s.; Parsley, per doz. bunches, 6s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 3s. to 6s.; Potatoes, per bushel, 5s. to 10s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsafy, do., 1s. to 1s. 6d.; Savoys, per doz., 2s. to 3s.; Scorzoneria, per bundle, 1s.; Shallots, per lb., 8d.; Spinach, per bushel, 3s. 6d. to 6s.; Turnips, old, per bunch, 6d., young do. 2s.

## ANSWERS TO CORRESPONDENTS.

**NEW POLYANTHUS (J. H. Maw).**—It is evidently of the Cowslip race, and will therefore be called a *Polyanthus* in gardens. It is a fine thing. —**NAMES OF PLANTS (F. M.).**—*Eranthis reticulatus*.—(Salmoniceps).—1 and 2, *Scdum elæagnatum*; 3, *Saxifraga hypnoides*, var. *elongata*; 4, *S. hypnoides*; 5, *S. paniculata*.—(Highfield).—1, *Prunus virginiana*; 2, *P. Padus*. There is nothing remarkable in the variegated *Sycamore* leaf. —(A. G. H.).—*Epacris heteromera*.—(M. Ryan).—1, *Pyrus pinnatifida*; 2, *Mespilus Smithii* (*grandiflora*); 3, *Pyrus sinatica*; 4, *Prunus Padus*; 5, *Crataegus Pyracantha*; 6, *G. punctata*; 7, *Eriobotrya japonica*; 8, *Euonymus japonicus argenteus*; 9, *Euonymus japonicus argens*; 10, *Stachys lanata*; 11, *Gnaphalium margaritaceum*. —**IMYTES (Anon).**—An interesting sport. Green flowers, however, sometimes occur not only among *Primroses*, but also among *Roses* and *Dahlias*. —**AZALEAS (W. T. C.).**—The leaves of some Azaleas always become marked like those you have sent; when young, the variegation is very apparent. —**VARIEGATED LEAVES (J. M.).**—If the variegation is constant, it is worth trying to preserve it.

**The Ancient Employment of Flowers.**—If Mr. Grindon will be good enough to consider that my remarks (see p. 328) were addressed to his statement, that in "the classical authors there is no allusion ever met with to a posy or nosegay," and not to his present assertion that "there is no mention made of a bouquet," I am sure that he will see that these are two different things.—W. M.

# THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

## LOW NIGHT TEMPERATURE FOR VINES.

It has often occurred to me that the night temperatures recommended for Vines during the early stages of forcing by most Grape growers, if not by all, were extravagantly high, compared with the temperatures of those countries where the Vine thrives naturally, so far as I have had an opportunity of judging of the probable night temperatures of those countries by the mean temperatures furnished respecting them. As a rule, a night temperature of 65° is recommended for the Black Hamburgh and other hardy sorts before they come into flower, and 70° when they come into flower, with a rise of 20° or 25° by means of sunheat. For Muscats, 5° are added at these stages, making the night temperature for them 70° or 75°, with a proportionate rise during the day. Now these night temperatures are actually higher than the mean temperatures of the month of May (about which time the Vines are in flower) in those countries where the finest varieties of the Grape arrive at the greatest perfection. Surely, in this country, where everything connected with the culture of the Vine is attended with great expense, especially in the way of fuel, and seeing it is acknowledged that fire-heat assistance is only a necessary evil, at all times to be dispensed with as far as possible in Grape-growing, it would be worth while to try if we could not succeed by treating the Vine to its natural temperature. A lower temperature for exotics might with reason be advocated in this country, where the nights are long and the days dull; but, except under particular circumstances, never a higher one than that of the country where the plants thrive naturally. Yet this is the case with the Vine, so far as I can make out, and your readers can satisfy themselves on the point by comparing the temperature of Vine-growing countries, from the time the Vines begin to grow till the fruit is set, with our artificial forcing temperatures up to the same period, as recommended by our eminent Grape-growers. It is of no use arguing that good Grapes have been produced by our present high-pressure system. I admit this, knowing that plants will thrive for a time under conditions widely different from what they are accustomed to in their natural habitats, but the end will be unsatisfactory. It is notorious, that lasting instances of successful Grape growing are the exception—in fact, uncommon. Successful exhibitors are continually coming to the front, and disappearing again after a brief period—the duration of their success perhaps depending a good deal upon the number of Vineries at their disposal, and which they can run through one by one in succession as the hey-day of their vigour wanes. There are doubtless various reasons for this state of things, but I am convinced that failure in a very great many cases is caused by unduly high and exhausting temperatures. An excessively high temperature is not good for plants under any circumstances, but when such is maintained by artificial means, such as hot-water pipes or flues, the evil is greatly increased. Physiologists tell us, and experience proves, that plants require rest as well as animals. They are at work when perspiration is carried on actively from their foliage under the light and heat of the sun, and they are at rest when perspiration ceases at night, in the absence of light and under a considerably reduced temperature, allowing the plants to recuperate after the day's work, and store up sap and energy for another day. This is what takes place under natural conditions; but what happens in a forcing house—a vinery for instance? During the day, under the combined influence of fire-heat and sun-heat, perspiration goes on at a rapid rate; at night comes a reduction of temperature, but not always a reduction of the perspiration. The outdoor thermometer is perhaps at 32°, or lower, but with the assistance of the pipes, so hot, may be, that they would burn the hand, the temperature of the vinery is maintained at the orthodox figures of 70° or 75°; the moisture which should have saturated the atmosphere of the house, and arrested the

demand upon the foliage of the Vines, is streaming down the glass in a condensed form, and the leaves themselves are as dry as they were at noonday, when they ought to be gorged with sap and have some to spare. This working day and night goes on, and spider and thrips make their appearance to complete the destruction of the already debilitated foliage; the same happens the next year, and the next, and then comes the end, so far as good crops are concerned. Considerations of this kind have led me to doubt very much the propriety of a high night temperature for the Vine. For the last few years, therefore, I have adopted a considerably lower scale of temperature than is usual, preferring much to be guided by the state of the weather out-of-doors, and not being particular to a difference of 10° or 12° in the night temperature, if a subsidence during cold weather was deemed necessary. From experience gained in this way, and influenced, I must say, by the price of fuel, I was led to think that a lower temperature still might be adopted with safety and advantage, and so sufficiently confident was I of this that I subjected one Muscat house to the experiment, considering that if the Muscats withstood the ordeal, there could be no doubt about the more hardy varieties. Fire heat was first applied to this house on the 1st of March, by turning the heat on at six o'clock in the morning, and turning it off again at two in the afternoon; giving the Vines a day temperature of from 70° to 85°, according to the weather—the thermometer, as a rule, falling to 50° or 55° by dusk, and to 45° in the morning, sometimes to 40°. This treatment was continued till April 8th, by which time the bunches were well out and the shoots stopped. From this date till May 10th the heat was turned off at six p.m., being turned on at six a.m., as before, except in one instance, noted in the following table, and on two or three occasions between the 19th and 26th of April, when the heat was turned on again from nine till ten p.m. (one hour), as a precaution, the weather being cold at the time. The temperature of the vinery by nine or ten o'clock p.m. was generally a little above or below 60°, the pipes having cooled by that time; and the table here given shows the minimum temperature of the vinery from before the Vines came into flower till the berries were set.

### TEMPERATURE OF MUSCAT VINERY.

(Recorded by a Negretti and Zambra's Self-Registering Thermometer.)

Lowest night temperature.		Lowest night temperature.		Lowest night temperature.

" 17	... 57	" 28	... 53	" 9	... 55
" 18	... 56	" 29	... 53	" 10	... 55**

The above table represents a night temperature nearly 20° lower than is considered essential for Muscats, and I may state that a better set of fruit could not be desired than we have. The foliage is healthy and of better texture than usual, and the wood unusually short-jointed and firm, running about six or seven joints to the foot. Probably a minimum of 45° might frequently have been reached without danger. This would have been risked, but a bed of leaves on the inside border prevented a lower temperature. Less than a barrow-load of coals was used after six o'clock p.m. during the thirty-three days, and I estimate that only about one-third of the coal was used that would have been necessary had the night temperature been kept to 70° and 75°, the usual figure for Muscats. The above table may be accepted, in every respect, as reliable, and I think disposes of the idea that a high night temperature is necessary for Muscats. More than this, we seem to have lost no time for the crop is just as far advanced as it was this time last year, though started at the same date. Since May 10th the morning temperature has stood at about 60°, the heat having been turned off at ten p.m.

J. S.

\* Heat turned off at 8 p.m. † Heat turned off at 6 p.m. from this date. ‡ Raisin de Calabrie coming into flower. § Muscats ditto. || In flower generally. ¶ Earliest bunches set. \*\* Greater portion of the crop set, and berries swelling.

## NOTES OF THE WEEK.

— ONE of the most beautiful sights conceivable is now to be seen at the well-known Salt-Hill Hotel, near Slough. It is a magnificent *Wistaria* in full bloom, covering the front of the hotel, and running round each end for some distance, making altogether a length of about 150 feet. It was planted against a strong iron support of the verandah, which support it has long since lifted bodily from the ground, and broken in pieces as easily as a man would break a lucifer match. A *Laburnum* grows against the house on one flank, and the contrast between the clusters of blue and yellow flowers is perfectly charming.

— ON the large trees at the south side of the church at Camden Town may now be seen an unusual development of *Chlorococcum vulgare*, which presents a very remarkable appearance. It was stated some time since by Mr. McNab, that this Lichen or Alga mostly occurs on the north side of trees, palings, &c., but on the trees at Camden Town it forms broad green streaks, which run straight up the tall stems at various points of the compass. Here, evidently, it has no preference for any particular aspect, the same tree frequently showing three or more distinct streaks all the way up, each at a wide horizontal angle with the others.

— IN the Botanic Garden at Cadiz, there is now growing a very large specimen of the Dragon tree (*Draecena Draco*), having a stem over 16 feet high, and 13 feet in circumference at the base. From the top of the stem proceed three huge main branches, which give rise to innumerable smaller ramifications, and form a handsome head. Three other public gardens of the same city possess each a specimen nearly as large as the foregoing, and in the various public and private gardens there are numerous specimens of this tree, of smaller sizes, to be met with.

— MOSSY rocks are often used with good effect in ornamental grounds in America. Wherever a bed is raised considerably higher than the level of the garden, or a stump is used as a centre-piece, there is an opportunity for the display of taste in disposing the rocks around it. If the rocks can be picked up in the woods, with plenty of moss upon them, they are greatly to be preferred to bare stones. They should be more or less inserted in the earth, and have the appearance of being in their natural position. This effect is not always easy to produce; but it is least difficult with a raised bed where the rocks are inserted in the side of the hill. Over these trailing plants are allowed to run indiscriminately.

— SEVERAL rare and interesting plants are now in bloom on the rockwork at Kew. Prominent among these are *Athemis Aizoon*, a very pretty and distinct perennial species, with white flowers and silvery leaves, resembling those of an *Achillea*; *Dracocephalum grandiflorum*, a plant too seldom met with, having large deep blue flowers; and *Cheiranthus arbuscula*, a kind forming a neat little bush, about six inches high, and bearing lilac-purple coloured flowers. There is also a nicely established plant of *Ramondia pyrenaica*, just commencing to bloom, and among plants more common than the above, yet particularly attractive at the present time, are *Lychnis Lagascea*, *Dianthus glacialis*, a species closely allied to the Alpine Pink, *Houstonia carulea*, and other interesting plants.

— THE Royal National Tulip Show took place on Wednesday last in the Aston Lower Grounds, Birmingham. Though the season has not been favourable for Tulips, judging from the specimens exhibited, it would seem that, even in the most favourable season, a better collection could not possibly have been obtained. There were exhibitors from Lancashire, Derbyshire, Worcestershire, Staffordshire, and other counties famous for the cultivation of Tulips. Taking the flowers as a whole, we can safely say that for quality and form certain varieties have very seldom been equalled. The cultivators from Nottingham and Derby carried off the best prizes, and many exhibitors who have hitherto been first in the contest now gained simply fourth or fifth prizes. The various classes were well represented, especially those for single specimens in one class—namely, the Bizarres. There were nearly 200 flowers from which to select ten prizes.

— FOREIGNERS, evidently, do not think much of us as fruit-growers or market gardeners—that is, if they are all of the same opinion as M. H. Mertens, from whose recent Report to the Belgian Minister of the Interior on the state of horticulture in the neighbourhood of London we extract the following:—"Fruit-tree culture is in such a poor condition in England, that well-trained trees are seldom to be seen there. Any palm-trees they have are formed without art or method, and frequently without any regard to vegetable physiology—a science which, with us, always goes hand-in-hand with the art of cultivating and pruning fruit-trees. Indeed, the palm-trees, single or double, is not much in fashion there, almost all the wall-trees being fan-trained. The pyramid is quite unknown, and their orchard trees are grown as tall standards. The market

gardening of the English is quite on a par with their fruit-tree culture, as they grow hardly any vegetables except Seakale and Rhubarb—in which, however, they excel, and which they devour in immense quantities." (1)

— MANY of the flower-beds near Hyde Park Corner are now filled with a mixture of *Mignonette* and dwarf Stocks, the effect of which is as pretty as their odour is grateful.

— M. NAUDIN, of Collioures (Eastern Pyrenees), has succeeded in cultivating *Phoenix pusilla* (commonly and erroneously known as *P. farinifera*) out-of-doors. This handsome Palm, which does not exceed 7 feet in height, has both flowered and borne fruit in M. Naudin's garden in the open air.

— MESSRS. PAUL & SON'S new *Rhododendron* garden at the Old Nurseries, Cheshunt, is now well worth inspection. It is of considerable extent, and is arranged in such a way as to be very effective, advantage having been taken of the inequality of the ground to have banks of *Rhododendrons* backed up by trees and shrubs of a larger growth.

— THE American Pomological Society intend to hold a great meeting in Boston on the 10th, 11th, and 12th of next September, in which all lovers of fruit are cordially invited to participate. As fruit culture is very extensively carried on in America, the meeting will doubtless be one of the highest importance and interest.

— AT a recent meeting of the Royal Horticultural Society, specimens of the hybrid *Cytisus purpurascens*, or (as it is now more commonly termed) *Cytisus Adami*, were exhibited, bearing on the same branches, in addition to its own peculiar flowers, the flowers also of each of its parents (*Cytisus Laburnum* and *C. purpureus*) very distinctly marked. This phenomenon, which has been noticed before, is interesting, chiefly as showing that the scion is undoubtedly influenced to some extent by the stock.

— WE learn from the *Revue Horticole* that M. Paillet, nurseryman at Chatenay-les-Sceaux (Seine), has lately received from America a singular variety of the Peach-tree. It is described as being a vigorous grower, with large leaves of a deep purple colour, with metallic reflections. The fruit is said to be of good size and quality, and, when ripe, of a uniform red colour over the entire surface of the skin.

— THE present damp, cool, and comparatively late season has considerably prolonged the beauty of our spring-flowering bedding plants. During the past three months the display at Belvoir has been unprecedented, and now, although quite as beautiful as ever, the beds are being broken up for the accommodation of their summer occupants. In Battersea Park some of the beds are still untouched and extremely gay, Daisies, Pansies, and *Violas* being now at their best, and *Collinsias* only just coming into flower.

— THE Government of Adelaide (South Australia) have organised an expedition for the purpose of exploring the as yet unknown region between Central Mount Stuart and the western coast. The party will be under the command of Major Warburton, and Mr. Berry will accompany it as botanical collector. It is intended to start from Beltana, and to follow the same route which was taken by the unfortunate Leichardt. Three camels will be specially attached to the expedition for the transport of botanical specimens.

— AMONGST notable trees, the *Peuplier de l'Arqueuse*, now standing in the Botanic Garden at Dijon, is worthy of record. This venerable Poplar was planted about A.D. 1400, and is consequently now about 470 years old. It is 100 feet high and 19 feet in circumference at its base. The age and dimensions of this tree are quite extraordinary, as the average duration of Poplar life seldom exceeds two centuries, and a Poplar trunk of even half the dimensions of the above is seldom seen.

— WE learn, from the current number of the Portuguese *Journal de Horticultura Pratica*, that Senor Edmond Goeze has been commissioned to proceed to England, in order to enquire into the circumstances under which the numerous and valuable collections of African plants, made by the late Dr. Welwitsch, were disposed of in his will. Our readers will, perhaps, remember that Dr. Welwitsch bequeathed a large portion of his collections to the Portuguese nation, by whom he was formerly employed as a botanical collector; but it appears that the Portuguese Government consider themselves entitled to the whole, on the plea that the collections were formed by Dr. Welwitsch while in their service. Senor Goeze purposes remaining about two months in England, during which time he will take possession of Dr. Welwitsch's bequest to the Portuguese, and also make a further collection of dried plants for the Herbarium of the new Botanic Gardens of the Polytechnic School. After this he will proceed, with the same object, to Paris, Berlin, and Vienna. The *Journal* also states that Senor Goeze has been commissioned to purchase in England the stoves and other heating apparatus for the new Botanic Gardens.

## THE GARDEN IN THE HOUSE.

## DINNER-TABLE DECORATION.

THERE is scarcely an entertainment of any importance given throughout the season that we are not informed, "The floral arrangements were supplied by Messrs. So-and-So"—a fact which shows that flowers on the dinner-table appear to be coming more and more into fashion every day, and certainly nothing tends so much to give a dinner-table a handsome and well-furnished appearance as good flowers, if well arranged; but there lies the difficulty. The arrangement must be good, for, if that is not done with taste, the table will be spoiled by the flowers, instead of being adorned by them. This happens sometimes from want of taste in the blending of colours, but oftener from the quantity of flowers used. Many are under the impression that the more flowers that can be packed into a stand, the richer and handsomer it will look; but that is a mistake; for, by packing, it acquires a heavy appearance, which no amount of dressing up with Ferns or Grasses can obviate, and the consequence is that too many of the latter are often used to make the stand look light. My own idea of the perfection of a stand is its light appearance, and to effect this too many flowers should not be used. Just place them so

trumpet, Astilbe (*Spiraea*) japonica, Rhodanthe Manglesii, small-flowered scarlet and pale pink Begonias, Maidenhair Fern, long-trailing sprays of Lygodium, and a few spikes of wild Grass. The plants put through the table were Ferns (*Pteris tremula*), round the base of which were arranged trusses of Stephanotis, white Rhodanthe, Maidenhair Fern, and *Lastrea Filix-Mas*. The baskets were of glass and contained Grapes, two of white and two of black; the four oval glass dishes had in them Cherries and Strawberries, the top and bottom a Melon and Pine. The small circular stands between the baskets were sugar dishes. In front of each person is one of the new shaped finger glasses, each containing a button-hole bouquet or coat flower; and on the water double scarlet Pelargoniums, pips and small leaves of sweet-scented Geranium Lady Plymouth. A. H.

**Window Flowers.**—When windows are filled with plants selected according to taste, and these are potted into moderately large pots, sufficient to last them through the growing season, they will require little other attention besides watering, which must be regularly and constantly done. Plants thus circumstanced, from the position they occupy, are extremely liable to suffer from drought, if there is the least neglect in administering their supply of water. This applies equally to all kinds of plants cultivated in such situa-

Prize Dinner-table Decoration.

as to let each one stand out distinctly by itself, never allowing it to crush up against its neighbour. I also always like to see very light flowers used in the trumpet, and here too many Grasses and Ferns can hardly be employed. Another fault which is constantly observable in floral arrangements is the blocking up of the view across the table. This should always be avoided as much as possible, as nothing interferes more with the comfort of those seated at a table than a clumsy stand of flowers or a pot-plant set so as to intercept the view, and shut them off from conversing with their friends opposite.

The accompanying illustration is a facsimile of that to which was awarded the first prize at the dinner-table exhibition, which took place in the Royal Horticultural Society's Garden at South Kensington, on May 15th, 1872, except that the table here represented is laid for sixteen instead of for twenty persons, as at South Kensington, and there were two Parian statues on that table which have been omitted in the engraving. The centre-piece was arranged thus:—In the bottom dish were scarlet Cactus blooms and trusses of Stephanotis placed alternately, with spikes of Astilbe (*Spiraea*) japonica and *Cyperus alternifolius*; around the edge, resting on the table-cloth, were fronds of *Adiantum Farleyense* and of *Pteris serrulata* alternately. In the top dish were pale-flowered zonal Pelargoniums, Lily of the Valley, and Maidenhair Fern. In the

tions. In order to protect them from injury, in consequence of the powerful rays of the sun striking directly on the sides of the pots, often very thin, and forming a mere shell round the roots, it is advantageous to set the pots containing the plants within others just large enough to contain them: the double sides, together with the small open cavity all round between the two, prevent the evil to a very great extent; and it may be still further prevented by choosing the exterior pot still larger, and filling the cavity between the two with moss, which should be kept damp.—D.

**Novelties in Coat Flowers.**—Permit me to commend to your correspondent "A. H.," and to all whom it may concern, *Narcissus gracilis*, the most elegant of all the genus, as an exceedingly pretty coat flower; like the whisky of an Irish friend, it is best when mixed with nothing; a black coat sets it off better than any foliage, while its delicate scent, graceful form, pale primrose colour, and the free arrangement of its cluster of five blooms, leave nothing further to be desired. As a contrast to this, let me mention *Aponogeton distachyon*, a Cape of Good Hope aquatic, that has been in flower all through the late mild winter, and which has not been injured in the least by the fall of the thermometer to 22° on two consecutive nights after warm weather during the last week in April. It is a thick fleshy flower, of very peculiar form, pure white, with black dots inside, these dots being the unopened anthers. This with a spray of Maidenhair Fern makes a capital "button-hole," and may be still further commended for its "staying" powers.—W. T. P.

## THE GARDEN GUIDE.

### SUFFOLK.

#### SHRUBLAND PARK.

SHRUBLAND, with its noble park and extensive woods, occupies a commanding position, as will be seen by our illustrations of it in *THE GARDEN*, Vol I., p. 350. Attached to the mansion is a noble span-roofed conservatory. Then follow balcony gardens supported by noble flights of steps and banks of shrubs, terminating in what are termed the panel gardens. Stretching away to the left, along a magnificent green promenade, is a succession of gardens in all styles—the Chinese, the English, the geometrical, the Swiss cottage and gardens, the maze, the subtropical, the Rosery, the conservative wall, the mixed irregular, and, towards the lake, the shrub garden and specimen trees, and glades of turf, the wild garden, rockery, &c. At the back of the architectural boundary of the panel garden are the French garden, ribbon borders, rough banks of roots, stones, and wild shrubs and flowers, a noble sweep of turf, a row of the finest sweet or Spanish Chestnuts in England, and so back to the mansion. On returning at the other end of the grounds, by the Swiss cottage, we pass through rock-work, hear the tinkle of running water, pass the end of the looking-glass garden, and so wind up a smooth lawn to the conservatory, close by which we find one of the most unique ribbon-borders in the kingdom, composed of lines of different heights of Smith's or Shrubland Scarlet Pelargonium, with its enormous strength and glowing trusses. The finest features at Shrubland are the site of the house, commanding views of the whole country to the south and west for miles; the house itself being in the castellated style; the beautiful lawn, sloping from it on the garden side, broken rather than occupied by the balcony garden; the fine steps, a hanging wood, cutting the upper terrace, &c., from the under series of gardens, and hiding them at all points, except from the top of the steps; the distant lake, recently formed; and the immense variety, as well as extent, of the series of flower gardens. The variety, in fact, sustains the interest, and one never wearies of them. The park is also beautifully undulated and well wooded, especially with old Spanish Chestnuts and Oaks. There are no Conifers of any great age or size at Shrubland. The kitchen garden is entirely hidden from the house, and is against the stables, which are near the house, but which are planted out. It is large and well furnished. Pines, Grapes, Melons, and orchard-house fruit of all kinds are well grown at Shrubland, and there is a large collection of plants in the different houses. Flower gardening, however, constitutes its chief feature, though fruits and vegetables, alike in-doors and out, are skilfully and successfully cultivated.—Proprietor, Admiral Sir George Brooke, Bart.; gardener Mr. Blair. Distance from Ipswich five miles.

#### HARDWICKE HOUSE.

This handsome building, in the Elizabethan style, stands in a commanding position in a well-wooded park, embosomed in plantations and surrounded by extensive pleasure-grounds and shrubberies. The late proprietor, Sir Thomas Geary Cullum, was a great planter and liberal patron of horticulture, and he and the present proprietress, Lady Cullum, devoted their leisure time to the furnishing and adornment of the estate. Thriving trees, shrubs, and plantations abound in all directions, and prove by their goodly dimensions and healthy state what may be done in the course of half a century to secure shelter and to create beauty by skilful planting. There are also a few fine old trees on the park and on different portions of the estate. An avenue of very tall Limes, and two of perhaps the finest oriental Planes in the kingdom may also be seen at Hawsted Place. Hardwicke House, from its elevated position, commands a fine view of Bury St. Edmunds, while a broad avenue of young Limes that runs into an old one of Sycamore, has the grand abbey gate as its central object in the far distance. The grounds are very extensive, consisting of a large geometrical flower garden skirted with Roses on tall arches, ribbon borders, broad lawns adorned with fine Cypresses, Cedars of Lebanon, Purple Beech, a grand Yew and other Elms; broad terrace walks, one with elegant bine and golden gates at each end, another with handsome stone seats; the Yew walk—a dense wall of Yew on each side, terminating with a vase and a far reaching view of the distant country. Then follow mostly new grounds of several acres in extent, consisting of Rosery, shrubberies, and raised herbaceous border or spring border garden, called My Lady's Garden. This portion of the grounds commands fine views of the undulations of the park and distant scenery. Passing through a shrubbery the Pinetum is reached, containing specimens of many fine Conifers. Turning to the right, we enter a dell or Fernery, formed of blocks mostly, as stone is scarce in East Anglia. This is of considerable extent and interest, abounding in walks and raised banks, and having a longish tunnel joining different portions together. Here spring flowers, beginning

with the Golden Aconite, followed by the Snowdrop, Violets, Forget-me-Nots, and Primroses, reign till the Ferns and other plants succeed them. The blocks are mostly furnished with Ivy and have a fine effect. Groups of Rhododendrons, which do well in the loam, dense masses of shrubs, Hollies, Laurels, Yew, and Box abound in all directions near the pleasure-ground walks; while at different points masses of Pampas Grass, Daffodils, and Rhododendrons are thrown in, while Primroses and Violets fill up with beauty and sweetness each vacant place; and so till the kitchen garden is reached. This is small, and ornamental as well as useful is written on its arrangements. Each crop has its separate block of land, the walks are lined with pyramidal Apple, Pear, and Plum trees, with a second bordering of cordons—single, double, diamonded, or spiral. Again, between these, pyramidal Roses rise, and all around the outside of the garden runs a double line of beauty, composed of flowering Thrift and the snowy white Saxifraga hypnoides. In front of the pretty cottage for the gardener, which stands in the centre of the kitchen garden, a row of standard Roses lines the main walks, backed by Sweet Peas and fronted with flowers; and yet but little ground is devoted to beauty, and the crops are crowded upon each other, to reap a maximum amount of crisp, sweet produce from a minimum of space. The glass houses are extensive, and reach from the conservatory attached to the house, in a continuous range, for several hundred yards. They are well furnished with Vines, Peaches, Figs, and plants; another block of houses is devoted to Pelargoniums stove plants, Azaleas, Camellias, Melons, Cucumbers, &c.—Proprietress, Lady Cullum; gardener, Mr. D. T. Fish. Distance from Bury St. Edmunds, 2½ miles.

#### ICKWORTH PARK.

The park at Ickworth is one of the finest in the kingdom; it is eleven miles round, contains nearly 2,000 acres, and is stocked with from 700 to 800 head of deer. It is richly wooded, and charmingly undulated. Here and there are some old Oak and other trees; but most of the timber is modern. The mansion is as magnificent as the park; it consists of a central dome—which can be seen for miles in all directions—and two wings, the whole extending 625 feet. The dome is 105 feet high, and its diameters (it is slightly oval) are 120 by 106 feet. The foundations of Ickworth were laid in 1792, by the Marquis of Bristol, who was also Bishop of Derry, and to whom a splendid monument, raised by the inhabitants of his diocese, forms an important feature in the park. At one end of the mansion there is a noble conservatory, and at the other a fine orangery furnished with a nice collection of trees in tubs. Around the base of the mansion are beds of shrubs skirted with flowers; then follow a narrow walk and a sloping bank of turf; we now go on to a lower level, or plateau, on which are groups of flower-beds or gardens furnished with bedding plants in the usual manner. Then come fine masses of shrubs broken with Cypresses and spiral trees, with groups of flower-beds amongst them, the whole encircled by a raised walk that skirts the pleasure-grounds and commands magnificent views of the far-reaching park in all directions. The effect of the garden and shrubs would be better were the shrubbery nearer the house, and the walks wider. The flower-beds, too, should be fewer and more massive. The old pleasure-grounds sweep away amid charming walks and fine specimens for miles, and command fine views of the park. The kitchen garden lies in a hollow, and contains about 8 acres of irregularly lying ground, surrounded and divided by fine walls. There are three fine ranges of Vineries, distinguished by the excellency of their produce, a fine new Peach-house, and a group of plant-houses by Beard, which answer well for the forcing and growth of flowers. There is also a large lake well furnished with fish, and the present noble proprietor has formed another and much more extensive one abounding with wild fowl.—Proprietor, the Marquis of Bristol; gardener, Mr. Robert Squibbs. Distance from Bury St. Edmunds, between three and four miles.

#### CULFORD HALL.

This stands on one side of an extensive and finely-wooded park, near a large sheet of water. The gardens around the house are small, and terminated by a church, which has been rebuilt in a beautiful and substantial manner by the present proprietor. The lawn contains some striking Irish Yews and Pinuses, and a flower garden in front of a new conservatory and fernery. The latter has recently been extended, water has been led over its rocks, so as to fall into a pool below, and a flight of steps enables the spectator to look down upon it. Passing along well-kept walks, past the church-yard, through a shrubbery and small out-of-door fernery, the noble kitchen garden is reached. This consists of eight or ten acres, in two divisions, surrounded with fine walls. The whole of the vegetable quarters are shut in from the main walks by a turf verge, and dense Yew hedges, which are clipped twice a year. This gives the garden a dressy appearance, and the Yew and Grass contrast admirably

with the white, glistening gravel of the walks. The main range of glass houses stretches right across the garden on a raised terrace, supported by a low retaining wall crowned with vases. In the centre of the range stands the gardener's cottage, and directly in front of it, and extending some way beyond, a large space is cut out of the kitchen garden, right across, and, shut out by the Yew hedges, laid down in Grass, and formed into a flower garden. The beds are small—the design elegant, and the effect is unique and grand. In addition to this, the whole of the raised platform devoted to the Vine borders, &c., is laid out in ribbon-borders, carpet bedding masses, &c., while sundry other borders are given up to seedling Pelargoniums, herbaceous plants, annuals, &c. The kitchen garden is thus centred and fringed with flowers. The glass is most extensive, consisting of Vineries, Orchard houses (immense in size), Fig houses, Peach houses, Melon houses, pits and frames, Strawberry houses, &c., and the quantity of fruit grown is very great, and its quality all that can be desired. A glass roof with a canvas front is also used for the growth of Apricots on walls, and answers admirably. A fine collection of Azaleas and the usual stove and greenhouse plants for furnishing and cutting are grown, and, as everybody knows, Culford has been the birthplace of Mrs. Pollock and of most of the best tricolor Pelargoniums now in cultivation.—Proprietor, the Rev. E. R. Benyon; gardener, Mr. Peter Grieve. Distance from Bury St. Edmunds, four miles.

## THE ARBORETUM.

### BLASTING AND BURNING LOGS AND STUMPS.

The difficulty of burning stumps lies in their solidity. It is by no means easy to burn a solid stump entirely, but, of the various plans which have been devised for this purpose, such as saturating the stump with petroleum, saltpetre, &c., the following cheap and easy method, as described in the *American*

American method of burning stumps.

*Agriculturist*, appears by far the best, and is much employed in America, where the destruction of innumerable stumps is a necessity of civilisation. With a 2-inch auger, bore a vertical hole in the centre of the stump from the top to the bottom. Then in the side of the stump, close to the ground, bore a horizontal hole towards the centre, so as to open into the bottom of the vertical hole. Drop some fire down the vertical hole into the centre of the stump. The draught of air entering by the horizontal hole (as shown by the arrow) will, like the draught of a chimney, maintain the combustion of the fire in the centre, which gradually spreads, and ultimately burns away the stump to a mere shell, which is readily knocked to pieces. It is stated that many stumps thus burned have had a great portion of the large roots consumed far into the ground.

Blasting, however, is a much more expeditious mode of clearing away stumps, and the time thus saved may well compensate for the trifling expense of the powder, &c. If a little powder is used, and the stumps skilfully broken up into fragments or split, they may be burned without difficulty, and the fire will penetrate through the crevices opened by the force of the powder and eat out the roots until they are beyond the reach of the plough. There only needs to be care exercised to bore the hole in the right place, and not use too much powder. The hole should be an inch and a half in diameter, and should penetrate to the centre of the stump. It should not be too low down, lest the bottom should blow out, and the force be expended in shattering the ground instead of the stump. Judgment should be used in so selecting the spot to put the powder that there may be an equal thickness of wood all around it, in which case the stump will be split

into four or five equal pieces, generally into as many as there are large roots attached to it. If this is properly done, and the stump is sound, some very good "knees" are sometimes got out, which are saleable for various purposes, more especially for ship or boat building.

The following is one of the best ways of putting in the powder:—For a large stump of 2 or 3 feet thick, about 3 inches depth of coarse blasting powder, the grains of which should be as large as Peas, in an inch-and-a-half hole, would be sufficient. About 18 inches of fuse should be left outside of

Mode of blasting a stump.

the hole. The end of the fuse should be put into the centre of the powder, and dried sand then poured into the hole until it is full; or the steel screw-plug described below may be used instead of the sand. A coarse iron wire should be thrust into the sand several times, to consolidate it and pack it closely around the fuse. The outside end of the fuse should then be split with a knife for half an inch, and shredded somewhat, then lighted with a match. It will require over a minute for the fire to reach the powder, during which time a place of safety should be sought. One may stand 100 feet away with safety, if too much powder is not used. A proper quantity should leave the stump in such a condition that the fragments may be prized out with a bar, or drawn out by a horse. Experience alone can teach what is a proper quantity to use.

For splitting logs by blasting, an ingenious method is thus described by Mr. T. J. Kane, of Illinois:—"Having many fence-posts to split out of large white Swamp and Burr Oak logs of a roughness and knottiness that made blasting necessary, I went to a machinist and ordered a steel screw made about 3 inches long, tapering so as to tightly fill an inch-and-a-quarter hole, with a small hole through its centre, to admit of a fuse and an added inch square on top to turn or screw it in with a wrench. Bore to the centre of the log with a 1½-inch auger, put in powder sufficient; screw in steel plug, pass fuse to connect with powder, make a square mortice in a heavy block, say equal in size to a 4×4 scantling, to fit the top of the screw; connect this mortice with a hole to pass the fuse through.

Log-splitting by blasting.

Steel screw-plug.

This will prevent the screw from blowing away with the explosion. As the proof of the pudding is in the eating, I would testify that I have used this screw three years, have made 5,000 posts, and it is now as good as ever."

### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Lardizabala biternata.**—This is the finest addition to our wall-plants that has been made for many years; it is evergreen, and the leaves are among the most beautifully-formed that we know of. We saw it in fine health on a wall at Heatherside.

**Illicium religiosum.**—In the nurseries at Heatherside, in Surrey, this interesting shrub, rarely seen in our gardens, and then usually as a wall or a pot-plant, thrives well in peat beds, and forms a very ornamental evergreen shrub.—R.

**Comparative Longevity of Trees.**—The following table, based on an examination of the annual concentric layers of the oldest known trees, appears in a recent number of the *Illustration Horticole*. Judas tree, 300 years; common Elm, 335; common Ivy, 450; common Maple, 516; White Birch, 576; Orange-tree, 630; Evergreen Cypress, 800; common Olive, 800; Walnut, 900; Oriental Plane, 1,000; common Lime, 1,100; common Fir, 1,200; common Oak, 1,500; Cedar of Lebanon, 2,000; Taxodium distichum, 3,000; Yew, 3,200.

## THE LIBRARY.

### FIELD AND FOREST RAMBLES.\*

To those who may feel interested in an excellent account of the natural resources and products of the Canadian province of New Brunswick, we cordially recommend this well-written work as one of no ordinary value. The author, while modestly disclaiming all pretension to put it forward as an exhaustive treatise on the natural history of a district of large extent, and hitherto but little studied, appears to us to have omitted nothing deserving of notice in the animal life and main features of the country. The past and present condition of the natives; the life of the backwoods settlers; the various animals, birds, reptiles, and fishes; the climate, scenery, and geology of the province, are successively described in a manner which testifies to the knowledge and observant research of the writer. The book has also the attractions of a pleasing style and clear and graphic language. Dr. Adams has long been known as an ardent and accomplished naturalist, and those who have enjoyed his previous works on the natural history of India, the Nile Valley, and the Maltese Islands, will not fail to welcome his present volume as a valuable contribution to the spread of general knowledge. We have ourselves been greatly pleased and instructed by our perusal of "Field and Forest Rambles," and give the following extracts as specimens of the style and spirit of the work when treating of such matters as are likely to interest the readers of THE GARDEN:—

#### FORMATION OF SWAMPS.—THE PITCHER PLANT.

The moss swamps, or "carbon barrens," are met with throughout the region, either in the open or in the forest. They appear to have been originally formed from melted snow accumulating in hollows, where in process of time mosses and other aquatic plants gained the ascendancy, transmuting the surface into a soft bog, which gradually dried up until the decomposing weeds formed a soil where the Coniferous trees took root; first in small numbers here and there, their dwarfed dimensions and outward surfaces densely covered with trailing moss and lichen, showing a struggle for existence. In the less reclaimed parts we find thickets of Alder, Willows, &c., while the Labrador Tea plant (*Ledum palustre*) and other shrubs flourish on the bog generally, where the hare and musk-rat make their tracks, the latter towards some Reed-covered pond not yet fully overrun by aquatic plants. Thus it would seem that many of the smaller lakes are steadily disappearing; the rate, however, at which this is going on cannot, as a matter of course, be accurately computed in a comparatively speaking newly settled country; but I have been assured, on the authority of residents, that many barrens now exist where lakes stood not fifty years ago. Some barrens may have both effluent and affluent streams, but many are mere hollows fed by the melting snow on their sides. The barren is, moreover, a favourite feeding ground of the reindeer, where it plunges up the snow with its snout and feet in quest of moss and lichen, diving, in a remarkable manner, the particular spots where these plants grow in luxuriance. Conspicuous among the flora are various sorts of Orchises, remarkable for elegance and beauty, while the well-known Pitcher plant (*Sarracenia purpurea*) is still more attractive, on account of the remarkable construction of its foliage. It would be difficult to assign a reason for this unusual construction of the leaf, inasmuch as there is no need of any such contrivance to hold water, seeing that the plant is always well supplied from the wet bog in which it grows, unless, as indicated by Gray, the drowned insects furnish manure to nourish it. What induces the fly to go into the cavity? Perhaps attracted by the hope of procuring subsistence, after traversing the part covered with bristles, it finds itself unable to return; or, losing its footing, falls into the well, from whence it is unable to extricate itself on account of these obstacles.

#### EFFECTS OF FROST ON FOREST TREES.

I was awake several times by the cracking of the branches and trunks of the forest trees, consequent on the lowness of the temperature, sounds to which my companions had been accustomed, but they were novel to me, and towards midnight became so frequent and loud that one might have imagined pistols were being fired all around the camp. In certain forest tracts it will be noticed that Spruces, especially the black sort, also Birch and other hard and soft-wood trees, are furrowed by deep longitudinal seams, extending often throughout the entire length of the trunk, and even penetrating

\* "Field and Forest Rambles; with Notes and Observations on the Natural History of Eastern Canada." By A. Leith Adams, M.A., M.B., F.R.S., F.G.S.; Staff Surgeon-Major. Author of "Wanderings of a Naturalist in India," "Natural History and Archeology of the Nile Valley and Maltese Islands." London: Henry S. King & Co., 65, Cornhill, and 12, Paternoster Row. 1873.

to the pith. This splitting of the wood is owing to extreme cold acting on the vegetable fibre, and no doubt produces the reports above-mentioned, which are also occasioned by the snapping across of the decayed branches. I did not observe the longitudinal rents in saplings; it may be for the reason that their fibres admit of more elasticity than the old tree. Moreover, although the rent does often extend to the centre, there is seemingly no evil effect on the health of the tree, and in the course of a few years it gets filled up by new bark, when the outline has much the appearance of the seam produced by lightning. The explosion consequent on such a rent is often startling; and although the fissure may not be evident immediately afterwards, it opens out after the thaws of spring. My always obliging friend, Mr. Edward Jack, to whom I am much indebted for valuable information on forest lore, informed me that the trees for the most part affected grow in exposed places, such as ridges where the north wind plays. Indeed, in felling Maple and other hard-wood trees for firewood, I have been astonished to observe how deeply the cold will penetrate into the substance of the stem without disorganizing or seemingly impairing the vitality, even to the freezing of the central fibres. The authority above named moreover assured me that trees covered with moss were not subject to these rents, being, no doubt, protected thereby. The effects of cold are, moreover, exemplified by the quantities of last year's growths to be seen strewn the snow around the trunks of both the evergreen and deciduous-leaved trees; hence there is a cropping of the tips of the branches in these latitudes not observable in the trees of milder climates. And no doubt from this cause it is that not only the leaf falls sooner and assumes a brighter tint than in central Europe, and that the former have fewer brauchlets as compared with corresponding species in milder climates.

#### THE TREES IN AUTUMN.

October 5th.—Splendid autumn weather; more enjoyable than any of the months of summer, as there are no insects to annoy, and the heat is subdued. Many of the hard-wood trees have now put on their gorgeous autumnal attires, always most varied and beautiful in saplings. I notice that the first leaves to open out in spring are the first to change colour in the fall; and these are usually near the extremities of the lower branches, and thus fully exposed to the sunlight; hence, Maples in the middle of the forests do not change colour so soon as trees on the skirts or in the open. As to the change in the coloration of the leaf, as displayed in the Canadian forest, it may, I think, receive the deep tinge of colouring from a sudden check to the circulation through cold drying up the sap, inasmuch as I have always found that as soon as the change begins to appear, then the connection of the leaf-stalk with the branch is so slender that there is no difficulty in separating the two; whereas in the healthy leaf this is accomplished with difficulty. And no doubt the low temperature, either by a sudden effort, or by causing a strangulation at some point (perhaps the point of junction between the stalk and stem), brings about the colorations alike remarkable for their brilliancy and variety, as compared with the leaf of more temperate climates. To persons who have not seen them before, there is an amount of grace, elegance, beauty, and variety in the grouping and coloration of the Canadian forest trees at this season really beyond conception. The bright and variegated hues of the Maple and Moose wood, with the Birch, Beech, &c., either dispersed, grouped, or solitary, form beautiful pictures, each tree vying with the others in the transcendent beauty of its dapplings and shadings, which, coupled with the cool bracing climate, create such happy feelings in the lookers-on, that I think if the question is asked the traveller what he most admired in a Canadian forest, he would unhesitatingly decide in favour of the autumnal change of the leaf.

#### GARDEN ACROSTIC.

HERE tender flowers and stately Palms,  
Afford a glad surprise,  
And Orchids chaste unfold their charms,  
Beneath our murky skies.

1. Erst he o'erran the Roman world  
And Europe's kings to ruin hurl'd,  
His ruffian mind may still be traced  
By universal want of taste.
2. No lover ever loved more truly yet.  
Than did this luckless wight his Juliet.
3. He should have held his rights more dear,  
Than barter them for lust of cheer.
4. Through cloud, through sunshine, thunder-storm, or shower,  
I rush along at forty miles an hour.
5. I always go before the King,  
No man would miss me more;  
Indeed, without my constant help,  
He cannot even snore.

SALMONICEFFS.

## THE INDOOR GARDEN.

### CYPRIPEDIUM VILLOSUM.

This robust-growing free-flowering species from Bhotan has a close-tufted habit and bright green leaves, measuring from 12 to 14 inches in length, and about an inch in breadth. The bases of the leaves are spotted behind with purple. The flowers, which are large, are borne singly on scapes from 9 to 12 inches high, both scapes and flowers being thickly beset with brownish hairs. The flowers are partly green and partly of a bright cinnamon-brown colour, and have a very glistening appearance, shining as if varnished. The accompanying illustration shows the size and general contour of blooms produced on well grown specimens. This species grows well in an ordinary plant stove or intermediate house planted in a compost of turfy loam, peat, and dried cow-dung, and may be treated as recommended for the other species. It is not so fickle as many of its congeners, and generally flowers during the spring, lasting a month in perfection.

F. W. B.

### HALF-HARDY AGAVES.

THE following make splendid specimens, admirably adapted for the embellishment of large greenhouses or conservatories, and also for the ornamentation of flights of steps, for placing in vases upon terrace walks, or for the thousand-and-one situations which may be found for such things in a garden during summer. Agaves are specially adapted for such situations, because they enjoy full exposure, and even our hottest summer days only serve to intensify their colours and markings. Such kinds as are here enumerated, though not altogether hardy, may be grown by persons who have no glass structure whatever; inasmuch as they can be safely stowed away in a coach-house or stable, or even in a cellar during winter. In such situations they must, however, be kept quite dry, and excluded from light. They should, moreover, be dry before being placed in their winter quarters, when an old mat or two, tied over the leaves, is all that will be necessary, except during very severe weather, when a little extra covering may be given them. Agaves are popularly known as American Aloes, but they really have nothing to do with the genus Aloe. They are remarkable for their longevity, and it is asserted that they bloom only once in a hundred years. With most of the species this is true, in one sense, for the terminal bud running up in the form of a flower-spike so completely exhausts the plant producing it that death is the result.

**A. americana.**—This may be regarded as the type of the family. It forms a handsome plant in all stages of growth, whether the leaves are a foot in length or 6 or 7 feet in length, and 6 or 8 inches in breadth. They are thick and massive in appearance, somewhat sparingly furnished with spines at the edges, but armed at the point with a very formidable one.

**A. americana variegata.**—This beautiful form of the plant just alluded to, attains about the same size, and like it is of slow growth. The centres of the leaves of this variety are dark green, whilst the margins are broadly banded with rich yellow.

**A. americana medio-picta.**—This is not so robust as the two previously named kinds, and it differs from them in having the central portion deep orange yellow, and the margins green; the edges of the leaves are furnished with brown spines, and the point terminates in a long stout one. It will be well to give this a little extra covering in winter.

**A. americana striata.**—This, although less handsome than the

former, is a beautiful variety, and grows to about the same dimensions. The ground colour is glaucous green, irregularly streaked throughout the entire length with yellow or white. It is very handsome, and very desirable as a contrast to the others.

**A. coccinea.**—The leaves of this are very thick and massive, the colour is intense deep green; the apex is armed with a formidable red spine, and the edges more sparingly with smaller ones of the same colour, from which its specific name is derived.

**A. lophantha.**—This is a distinct and less massive plant than the preceding. Its leaves are some 3 feet long and nearly 2 inches wide at the base, the ground colour being dark green, with a pale green central band; the edges are bordered with white, and the point ends in a red spine. It forms a handsome specimen, and should have a little wrapping in winter.

**A. Jacobiana.**—A noble plant, the leaves of which are some 2 or 3 feet in length and about 6 inches broad, armed at the point with a long stout incurved spine; the colour is deep green, and the edges are furnished with large flat spines.

**A. ferox.**—This is a massive-looking species, with leaves very deep green in colour, and profusely armed with stout and sharp dark reddish brown spikes. It is, in fact, a veritable noli-me-tangere.

**A. mitriformis.**—When this is well grown, its leaves are from 20 to 30 inches in length, and some 3 or 4 inches in breadth, terminated by a long brown spine, and the edges are furnished with smaller ones of the same colour; the leaves themselves are very deep green. It is a fine ornamental species.

**A. potatorum.**—This is a magnificent species, the leaves of which attain upwards of 3 feet in length and 6 inches in breadth, and terminate in a very long stout spine. They are very deep, heavy green in colour, with lobed edges, where they are furnished with large flat brown spines.

**A. Salmiana.**—The leaves of this species are very massive, and borne on large plants, are upwards of 4 feet long, terminating in a very long, round, straight brown spine; the thick leaves are dark green, and are armed at the edges with large recurved dark brown spines.

**A. picta.**—At first sight this might be mistaken for *A. americana variegata*. Closer inspection, however, soon dispels the delusion, for the leaves are longer, narrower, and not disposed in the compact rosulate manner of those of that plant. They measure from 2 to 3 feet in

length, but do not reach more than about 2 or 2½ inches in breadth, terminating in a long, stout, red spine. The centre of the leaf is dark bright green, having a broad marginal band of pure white, and the edges are furnished with small red spines. It is a very handsome plant, but a little more tender than the two previously-named kinds.

**A. picta brevifolia.**—In most respects this resembles the preceding, but, as its name implies, the leaves are shorter, and the marginal band is frequently suffused with yellow instead of white. Owing to the leaves being shorter, too, they are not so pendulous or twisted about as those of *picta*.

**A. mexicana.**—A fine stout, compact-growing plant, with leaves from 2 to 3 feet in length, and about 4 inches wide, or, perhaps, a little more in the widest part, very glaucous green, and armed at the point with a very stout spine, but at the edges the spines are somewhat small and distant.

**A. Humboldtiana.**—This superb plant is rare, but very handsome and distinct. The leaves are somewhat stout, some 3 feet long, broadest in the centre, deep green, and furnished at the top with a stout, reddish brown spine, the edges being closely set with smaller spines of the same colour.—*Farmen*.

*Cypripedium villosum.*

## THE FLOWER GARDEN.

### MR. DARWIN ON PRIMROSES, COWSLIPS, AND OXSLIPS.

As much confusion still exists among cultivators as to the relationship of these plants and the forms of hybrids that spring from them, we have thought it well to reprint from the *Journal of the Linnean Society* the more important points in Mr. Darwin's remarkable essay on the subject, in the hope that it may serve to clear up a matter on which many of our correspondents seem to be interested.

The claim (says Mr. Darwin) of the above three forms (namely, the common Cowslip, Primrose, and Bardfield Oxlip) to be ranked as distinct species has been discussed at greater length than that of almost any other plants. Linnæus considered them varieties, as do some of the most distinguished botanists at the present day; whilst others who have carefully studied these plants do not doubt that they deserve to be ranked as distinct species. The following observations show, I think, that the latter view is correct; and they further show that the common Oxlip, which is found in most parts of England, is a hybrid between *P. veris* and *vulgaris*. The Cowslip differs so conspicuously in general appearance from the Primrose, that nothing need here be said with respect to their external characters. But some less obvious differences deserve notice. As both species are dimorphic, their complete fertilisation depends on insects. They emit a different odour. The Primrose, when legitimately fertilised, produces on an average many more seeds than the Cowslip, namely, in about the proportion of 100 to 55. It is a more important distinction that both the long-styled and short-styled forms of the Primrose, when illegitimately fertilised with their own pollen, are much more fertile than the corresponding forms of the Cowslip when similarly treated. When long-styled plants of the Cowslip are protected by a net, so that they cannot be visited by insects, they yield no seed, as I found to be the case with no less than eighteen plants; and the short-styled form is only a little less sterile. The long-styled Primrose, on the other hand, when similarly protected, produces a considerable number of capsules, of which twenty-three contained on an average 19·2 seeds: the short-styled form produces under these circumstances fewer capsules, of which fourteen contained on an average only 6·2 seeds. This great difference in the fertility of the Cowslip and Primrose, when all insects which are capable of exclusion are excluded, depends in part on the Primrose being innately much more self-fertile than the Cowslip, and in part on the former being much frequented by thrips, which, dusted with pollen, may often be seen crawling within the flowers.

The Primrose, as everyone knows, flowers a little earlier in the spring than the Cowslip, and inhabits slightly different stations and districts. The Primrose generally grows on banks or in woods, whilst the Cowslip is found in more open places. The geographical range of the two forms is different. Dr. Bromfield remarks that "the Primrose is absent from all the interior region of northern Europe, where the Cowslip is indigenous." In Norway, however, both plants range to the same degree of northern latitude. The Cowslip and Primrose, when reciprocally crossed, are far from fertile. Gartner crossed twenty-seven flowers of *P. vulgaris* with pollen of *P. veris*, and obtained sixteen capsules; but these did not contain any good seed. He also crossed twenty-one flowers of *P. veris* with pollen of *P. vulgaris*; and now he got only five capsules, containing seed in a still less perfect condition. Gartner knew nothing about dimorphism; and his complete failure may perhaps be accounted for by his having crossed together the same form of the Cowslip and Primrose; for this would have been an illegitimate as well as a hybrid union, and would consequently have been sterile in the highest degree. I was rather more fortunate in my trials: I crossed legitimately three flowers on the long-styled and three on the short-styled Cowslip, with pollen from the opposite form of the Primrose, and obtained one capsule containing the large number of forty-eight apparently good seeds. I crossed on the same plant six flowers illegitimately, with pollen from the corresponding form of the Primrose, and obtained three capsules, containing seeds so poor that there was no chance of their germination. I likewise fertilised twelve flowers of the Primrose, consisting of both forms, with pollen from both forms of the Cowslip, and eighteen flowers in the same manner with pollen of the Polyanthus. I should here state that the Polyanthus is a variety of the Cowslip, as I infer from their mongrel offspring being perfectly fertile *inter se*; and as there seems to be no essential difference in the action of Cowslip and Polyanthus-pollen on the Primrose, the results are here run together. Eight long-styled and seven short-styled flowers of the Primrose were legitimately crossed with pollen of the Cowslip and Polyanthus, and, together, they yielded six capsules, containing on an average thirty-seven

seeds, some of fine quality and some only moderately good. The pure Primrose, when legitimately fertilised by pollen from the Primrose, yields an average of almost exactly double this number of seeds, viz., seventy-one. Lastly, eight long-styled and seven short-styled flowers of the Primrose were illegitimately fertilised by pollen of the Cowslip and Polyanthus, and, together, they yielded only four capsules, containing on an average only thirteen seeds, some good and some poor. The Primrose, when illegitimately fertilised by pollen from the Primrose, yields an average of about forty-four seeds. We thus see that a cross between the same forms of the Primrose and Cowslip is far more sterile than a cross between the opposite forms. The Primrose, especially the short-styled form, when fertilised by the Cowslip, is less sterile, as Gartner likewise observed, than the Cowslip when reciprocally fertilised by the Primrose. I sowed the seeds produced from the several foregoing crosses; but none germinated except those from the short-styled Primrose fertilised by the pollen of the Polyanthus; and these seeds were the finest of the whole lot. I thus raised six plants, and compared them with a group of wild Oxslips, evidently produced from the same capsule, which I had transplanted into my garden. One of these wild Oxslips produced slightly larger flowers than the others, and this one was identical in every character (in foliage, flower-peduncle, and flowers) with my six plants, excepting that the flowers in the latter were tinged of a dirty red colour.

We have now seen that the Cowslip and Primrose cannot be crossed either way except with considerable difficulty, that they differ conspicuously in external appearance, that they differ in certain curious physiological characters, that they inhabit slightly different stations, and range differently. Hence those botanists who rank these plants as varieties ought to be able to prove that they are not as well fixed in character as are most species; and the evidence in favour of such instability of character does appear at first very strong. It rests, first, on statements made by several competent observers that, from seeds of the same plant, they have raised Cowslips, Primroses, and Oxslips; and, secondly, on the frequent occurrence in a state of nature of plants presenting every intermediate gradation between the Cowslip and Primrose.

The evidence, however, on the first head is of little value; for, dimorphism not being formerly understood, the seed-bearing plants were in no instance protected from the visits of insects; and there would be almost as much risk of an isolated Cowslip, or of several Cowslips, if consisting of the same form, being crossed by a neighbouring Primrose and producing Oxslips, as of one sex of a dioecious plant, under similar circumstances, being crossed by the opposite sex of an allied and neighbouring species. Mr. H. C. Watson, a critical and most careful observer, made many experiments by sowing the seeds of Cowslips and of various kinds of Oxslips, and arrived at the following conclusion, namely, "that seeds of a Cowslip can produce Cowslips and Oxslips, and that seeds of an Oxlip can produce Cowslips, Oxslips, and Primroses." This conclusion harmonizes perfectly with the view that in all cases, when such results have been obtained, the unprotected Cowslips have been crossed by Primroses, and the unprotected Oxslips by either Cowslips or Primroses; for in this latter case we might expect, by the aid of reversion, which notoriously comes into powerful action with hybrids, that both parent forms in appearance pure, as well as many intermediate gradations, would be produced. Nevertheless the two following statements offer considerable difficulty. The Rev. Professor Henslow raised from seed of a Cowslip growing in his garden various kinds of Oxslips and one perfect Primrose; but a statement in the same paper, perhaps, throws light on this anomalous result. Professor Henslow had previously transplanted into his garden a Cowslip, which completely changed its appearance during the following year, and now resembled an Oxlip. Next year again it changed its character, and produced, in addition to umbels, a few single-flowered scapes, bearing flowers somewhat smaller and more deeply coloured than those of the common Primrose. From what I have myself observed with Oxslips, I cannot doubt that this plant was an Oxlip in a highly variable condition, almost like the famous *Cytisus Adami*. This variable plant was propagated by offsets, which were planted in different parts of the garden; and if Professor Henslow took, by mistake, seeds from one of these plants, especially if it had been accidentally crossed by a Primrose, the result would be quite intelligible. Another case is still more difficult to understand—Dr. Herbert raised, from seed of a highly-cultivated red Cowslip, Cowslips, Oxslips of various kinds, and a Primrose. This case, if accurately recorded, is explicable only on the improbable assumption that the red Cowslip was not of pure parentage. With plants of many kinds, when crossed, one species or variety is sometimes strongly prepotent over the other; and instances are known of one variety crossed by another producing offspring which in certain characters, as in colour, hairiness, &c., have proved identical with the pollen-bearing parent, and quite dissimilar to the mother-plant;

but I do not know of any good instance of the offspring of a cross perfectly resembling, in a number of important characters, the father alone. Hence we cannot admit that a pure Cowslip crossed by a Primrose would ever produce a Primrose in appearance pure. Although the facts given by Dr. Herbert and Professor Henslow are difficult to explain, yet until it can be shown that a Cowslip or a Primrose, carefully protected from insects, will occasionally give birth to at least Oxlips, the cases hitherto recorded have little weight in leading us to admit that the Cowslip and Primrose are varieties of one and the same species.

Negative evidence is of little value; but the following facts may be worth giving:—Some Cowslips which had been transplanted from the fields into a shrubbery were again transplanted into highly-manured land. In the following year they were protected from insects, artificially fertilised, and the seed thus procured was sown in a hotbed. The young plants were afterwards planted out, some in very rich soil, some in stiff poor clay, some in old peat, and some in pots in the greenhouse; so that these plants, 765 in number, as well as their parents, were subjected to diversified and unnatural treatment; but not one of them presented the least variation except in size—these in the peat growing to almost gigantic dimensions, and those in the clay being much dwarfed. I do not, of course, doubt that Cowslips exposed during several successive generations to changed conditions would vary, and that this would occasionally take place in a state of nature. Moreover, from the law of analogical variation, the varieties of any one species of *Primula* would probably in some cases resemble other species of the genus: thus I raised a red Primrose from seed from a protected plant, and the flowers, though still resembling those of the Primrose, were borne during one season on a long foot-stalk like that of a Cowslip.

With regard to the second class of facts in support of the Cowslip and Primrose being ranked as mere varieties (namely, the well-ascertained existence in a state of nature of numerous linking forms), if it can be shown that the common wild Oxlip, which stands exactly between the Cowslip and Primrose, resembles in sterility and other essential respects a hybrid plant; and if it can further be shown that the Oxlip, though in a high degree sterile, can be fertilised by the pure parent species, thus giving rise to still finer gradational links—then the presence of such forms in a state of nature ceases to be an argument of any weight in favour of the Cowslip and Primrose being varieties, and becomes, in fact, an argument on the other side. The hybrid origin of a plant in a state of nature can be recognised, first, by its occurrence only where both presumed parent forms exist, or have recently existed; and this holds good, as far as I can discover, with the Oxlip; but the *P. elatior* of Jacq., which, as we shall presently see, constitutes a distinct species, must not be confounded with the common Oxlip. Secondly, by the supposed hybrid plant being nearly intermediate in character between the two parent species, and especially by its resembling hybrids artificially made between the same two species. Now the Oxlip is intermediate in character, and is identical in every respect, except in the colour of the corolla, with hybrids artificially produced between the Primrose and the Polyanthus, which latter is a variety of the Cowslip. Thirdly, by the supposed hybrids being more or less sterile when crossed *inter se*: but, to try this fairly, two distinct plants of the same parentage should always be crossed; for some pure species are more or less sterile with pollen from the same individual plant; and, in the case of hybrid dimorphic plants, the opposite forms should be crossed. Fourthly and lastly, by the supposed hybrids being much more fertile when crossed with either pure parent-species than when crossed *inter se*, but still not as fully fertile as the parent species.

From having many experiments in hand, I did not sow the seed obtained by reciprocally crossing Primroses and Cowslips with the Oxlips, and I now regret this; but I ascertained a more interesting point, namely, the character of the offspring from Oxlips in a state of nature growing near both Primroses and Cowslips. The Oxlips were the same plants which were subsequently transplanted and experimented on. From seed thus obtained, eight plants were raised, which, when they flowered, might have been mistaken for pure Primroses; but on close comparison the eye in the centre of the corolla was seen to be of a darker yellow, and the peduncles more elongated. As the season advanced, one of these plants threw up two naked scapes, seven inches in height, which bore umbels of flowers of the same character as before. This fact led me to examine the other plants after they had flowered and were dug up; and I found in all that the flower-peduncles sprung from an extremely short common scape, of which no trace can be found in the pure Primrose. Hence these plants are beautifully intermediate between the Oxlip and the Primrose, inclining rather towards the latter; and we may safely conclude that the parent Oxlips had been fertilised by the surrounding Primroses.

From the various facts now given, there can be no doubt that

the common Oxlip is a hybrid between the Cowslip (*P. veris*, Brit. Fl.) and the Primrose (*P. vulgaris*, Brit. Fl.), as has been surmised by several botanists. It is probable that Oxlips may be produced either from the Cowslip or the Primrose as the seed-bearer, but oftener from the latter, as I judge from the nature of the stations in which Oxlips are generally found, and from the Primrose when crossed by the Cowslip being more fertile than the Cowslip by the Primrose. The hybrids themselves are also rather more fertile with the Primrose than with the Cowslip. Whether the Cowslip or the Primrose be the seed-bearing plant, it is probably fertilised by the opposite form of the other species; for we have seen that legitimate hybrid unions are more fertile than illegitimate hybrid unions. Moreover a friend in Surrey found that twenty-nine Oxlips which grew in the neighbourhood of his house consisted of thirteen long-styled and sixteen short-styled plants; now, if the parent plants had been illegitimately united, either the long or short-styled form would have greatly preponderated in number. The case of the Oxlip is interesting; for hardly any other instance is known of a hybrid spontaneously arising in such large numbers over so wide an extent of country. The common Oxlip (not the *P. elatior* of Jacq.) is found almost everywhere throughout England where the Cowslip and Primrose both grow. In some districts, as I have seen near Hartfield in Sussex and in parts of Surrey, specimens may be found on the borders of almost every field and small wood. In other districts the Oxlip is comparatively rare; near my own residence I have not seen during the last twenty-five years more than five or six plants or groups of plants. It is difficult to conjecture what is the cause of this difference in number. It is almost necessary that a single plant, or several plants of the same form, of one parent species should grow near the opposite form of the other species; and it is further necessary that both species should be frequented by the same kind of moth. It is possible that such moths do not everywhere abound.

Finally, as the Cowslip and Primrose differ in the various characters before specified, as they are in a high degree sterile when intercrossed, as there is no trustworthy evidence that either plant, when uncrossed, has given birth to the other plant or to any intermediate form, and as the intermediate forms which are often found in a state of nature have been shown to be more or less sterile hybrids of the first or second generation, we must for the future look at the Cowslip and Primrose as good and true species.

#### PRIMULA ELATIOR, JACQ., OR BARDFIELD OXLIPI.

This *Primula* is found in England only in two or three of the eastern counties; and on the continent it has a somewhat different range from that of the Cowslip and Primrose. It inhabits districts where neither of these species live. In general appearance it differs so much from the common Oxlip, that no one accustomed to see both in the living state would afterwards confound them; but there is scarcely more than a single character by which they can be distinctly defined, namely, the linear-oblong capsule equalling the calyx in length. The capsules, when mature, owing to their length, differ conspicuously from those of the Cowslip and Primrose. Plants propagated by seed in a garden during twenty-five years have kept constant, excepting that in some cases the flowers varied a little in tint and size. Nevertheless Mr. Hewett C. Watson and Dr. Broomfield state that "exceptional instances to all the characters, taken singly, by which this plant is distinguished from *P. vulgaris* and *veris*," may be occasionally detected; it remains to be discovered whether these intermediate forms are not hybrids between *P. elatior* and *veris*, which often grow together. With respect to differences in function, both the long and short-styled forms of *P. elatior* are more sterile when fertilised by their own pollen than the corresponding forms of the Cowslip and Primrose when similarly fertilised.

Mr. H. Doubleday, who I believe first called attention to the existence of the Bardfield Oxlip in England, kindly sent me several living plants, which I subjected to trial for the sake of ascertaining whether they differed in their reproductive power from the common Oxlip. I did not think it worth the time and labour to ascertain whether the Bardfield Oxlip, when crossed with the Cowslip and Primrose, behaved like a distinct species; for if it can be clearly proved not to be a hybrid, and if the Cowslip and Primrose are specifically distinct, I presume that no one will any longer doubt that the *P. elatior* is likewise distinct.

Finally, although we may feel confident that *Primula veris*, *vulgaris*, and *elatior*, as well as the other species of the genus, are all descended from some primordial form, yet, from the facts which have been given, we may conclude that they are now as fixed in character as are very many other forms which are universally ranked as species. Consequently they have as good a right to receive distinct specific names as have, for instance, the ass, quagga, and zebra.

## HERBACEOUS PLANTS AT ASHRIDGE PARK.

AMONGST the many interesting and attractive herbaceous gardens now springing up in all directions, few promise to be more successful than that at Ashridge Park, the seat of Earl Brownlow, whose desire to grow every desirable hardy shrub and flower is most ably carried out by his energetic gardener, Mr. Gray, the discoverer of the pretty *Aemone Hepatica marmorata*, which, under his fostering care, is already beginning to form a conspicuously ornamental patch in one of the shrubby borders. Mr. Gray makes large use of a very pretty form of *Primula cortusoides amana*, which I do not remember to have seen anywhere else. It was raised some years since from one of the very first batches of seed sent out by Messrs. Veitch, and has been sedulously propagated. It has a much smaller flower than the usual form; but the colour is a much richer magenta, and it is not shaded with white towards the centre, like most of the ordinary varieties. The truss, too, is much denser and stouter, and the flower-stalks are produced in far greater abundance. It is extraordinarily hardy, standing any severity of weather, and increases with great rapidity, soon forming a dense patch of magenta and green, which for effect cannot easily be matched. Mr. Gray also grows *Phlox verna* with greater success than in any garden I have ever visited. He uses it as a wide margin to large shrubby borders, where its soft green leaves form a closely-fitting carpet densely studded with trusses of rose-coloured flowers, the effect of which is indescribably beautiful. A small round bed of *Myosotis dissitiflora*, thickly edged with *Thymus citriodorus aureo-marginatus*, struck me as very effective. Mr. Gray is as active among his florists' flowers as in the herbaceous garden. He has a large stock of a fine *Polyanthus*, and a Wallflower, apparently a hybrid between *Ch. Cheiri* and *Ch. Marshallii* or *ochroleucus*, that would do more than excite the jealousy of the accomplished guardian of the parterres of Belvoir.

H. HARPER CREWE.

*The Rectory, Drayton-Beauchamp, Tring.*

**Early Flowering Tulips.**—In the following list I have selected such varieties only as were all in perfection together on April 21st; and as they are sorts that were done blooming by the time the collection in general was in flower, the selection will be of value to anyone requiring early kinds to be got off the ground in time to allow early bedding plants to be put out:—*L'Immaculée*, fine pure white; *Vesuvius*, crimson; *Pottebakker*, yellow; *Pottebakker*, white; *King's Crown*, scarlet, belted with yellow; *Golden Prince*, light golden yellow; *Molière*, purple; *Duc Van Thol*, scarlet; *Joost Van Vondel*, vermilion, white feathered; *Van der Noer*, purplish puce; *Proserpine*, rose; *Vermilion Brilliant*, large scarlet; *Brutus*, scarlet, shaded with orange; *Duc Van Thol*, rose; *Van der Helst*, rose, bluish feathered; *Gloria Solis*, double crimson and yellow.—R. H. BARD.

**Aloysia citriodora (Sweet Verbena).**—Anyone who desires to see this old favourite plant grow freely and finely, and who wishes to have lots of it for cutting, not only for flavouring claret cup, but also for mixing with flowers in the drawing-room vases, should plant out a few plants of it at the foot of a warm south wall. The low front walls of plant and fruit houses are very suitable for this and for other plants of a similar kind. It is best not to attempt anything in the shape of training; but, on the contrary, to allow it to develop itself freely. You may then "cut, and come again" as often as you please. In all probability the first severe winter may cut the plants down to the ground; but then in early spring they will start up again from the bottom, and attain in a short time even greater development than before. It is easily propagated by means of cuttings; small pieces of ripened wood put in in March in a gentle hot-bed strike freely, and when potted off soon make nice plants. Young shoots made in heat will also strike in spring, if kept close and shaded; but cuttings made of ripe wood are best. Small pieces of half-ripened wood, in a shady place out-of-doors in August, will also root quickly, and make nice little plants for the following year.—E. HOBDAY, *Ramsey Abbey*.

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Golden Thyme.**—Permit me to state, in answer to the enquiries of Miss Hope, of Warren Lodge, and others, that the Thyme about which I wrote in THE GARDEN, is that which was sent out by Messrs. Fisher & Holmes, under the name of *T. citriodorus aureus*. It has stood the winter extremely well here.—D. T. FISH.

**Moss Balls for Bedding Plants.**—At Linton Park most of the bedding plants, when potted off, early in April, are each tied up roughly in a coating of Moss and then plunged out in frames, &c., in soil. The plants root into and through this Moss, and are very easily transplanted to their final positions in it without any injury whatever. The Moss is (of course) not disturbed in planting, the roots passing readily through it into the earth. Mr. Robson finds this an excellent plan.—R.

## FOREST VEGETATION IN SIAM (CHIN-INDIA).

THE South-eastern peninsula of Asia, lying entirely within the tropics, and watered by numerous rivers, is rich in the variety and luxuriance of its vegetable productions. The kingdom of Siam, which occupies a great part of the peninsula, extending from about 12° to 21° N. and from 96° to 105° E., is traversed through its centre by the river Menam, whose annual inundations, like those of the Nile, fertilise the great plain through which it flows, so that plentiful crops of rice, sugar, pepper, tobacco, coffee, and cotton, are easily raised by the inhabitants. Towards the N.E. the country becomes more mountainous and woody, and wild animals, including the elephant, rhinoceros, tiger, buffalo, leopard, bear, and crocodiles abound. Much of this part of the country is as yet little known. Our illustration, which represents a scene in a forest near the banks of the Cambodia river, between Nong Kay and Pak Lay, in lat. 18° N., well exhibits the exuberance and the variety of tropical vegetation in these regions—the Bamboos, various kinds of Palms, the Teak tree, the Sandal-wood and numerous other forest trees and climbers, rising in huge proportions from the tangled brush-wood, and, with an occasional glimpse of some wild animal, as it crosses an opening, suggesting all that the mind can conceive of the native aspect of a "forest primeval." The Grasses, as represented by the Bamboos well shown in our illustration, here attain almost the dimensions of forest trees, and are certainly not surpassed in grace of form by the Palms themselves. Fine as is the aspect of the Bamboos in the centre of our illustration, and impossible as it may seem to many to produce a like aspect of vegetation in this country, we have seen hardy Bamboos producing an almost equally good effect in the southern parts of England and Ireland.

## THE FRANKFORT PALM-HOUSE AND GARDEN.

WHEN, some three years ago, the Duke of Nassau resolved to dispose of his fine grounds and valuable plants at Bieberich on the Rhine, it occurred to some enterprising and public-spirited Frankforters that it would be an excellent thing if the rich collection of Palms, Rhododendrons, Azaleas, Camellias, Orchids, Mimoseæ, &c., could be purchased and removed to some suitable spot in the vicinity of their native city. To carry out this object, a company was formed with a capital of 300,000 florins, in shares of 250 florins; the municipal authorities granted a piece of land as a site, rent free for ten years, and in a very short space of time Frankfort possessed its Sydenham Palace and grounds in miniature. For proximity to the best end of the town no more favourable situation could have been selected, and, standing on the summit of a gentle slope, the building commands fine views of the Taunus range of hills and the surrounding country. The pleasure-grounds, which were originally only thirteen acres in extent, are being constantly enlarged, and during the process of enlargement and transformation present naturally a somewhat unfinished appearance. Considerable taste is displayed in the disposition of the beds, walks, fountains, and lake, no less than in the grouping of the trees and shrubs; and as the latter become more fully developed, the garden will lose the baldness and harshness of outline which betray its recent origin. With regard to the Palm house, this, if not distinguished exteriorly by elegance of form, is found by experience eminently adapted for the different purposes it was intended to serve. It consists of a large central hall or stove, containing in addition to a variety of Palm trees and tropical plants, such as *Latania Borbonica*, *Phoenix dactylifera*, *Caryota urens*, *Cocos Bontriana*, *Dracœna Australis* (25 to 30 feet high), *Dion edule*, *Aracaria Cunninghamii*, *Yucca*, *Aloe*, *Musa*, and *Chamaedorea*, a naturally arranged piece of rockwork, a cascade, &c.; also a winter garden or gallery, surrounding the stove, and stocked with Camellias, Roses, Orchids, Azaleas, and Rhododendrons; a music hall, and a refreshment room. The music hall is merely separated from the stove by a glass partition, so that whilst the ear is enjoying the classical compositions of Beethoven and Mendelssohn, the eye reposes on some of the choicest productions of nature. To modify the light, the roof is constructed of soft-coloured opaque glass, and the comfort of the audience has been still further considered by the adoption of a good system of ventilation. The building is some 168 feet in length, by 104 in breadth, and 54 in height. So attractive have the gardens been made by concerts, floral exhibitions, &c., that the daily attendance, without reckoning annual subscribers and shareholders, now averages 500 to 600. The finances of the company are in a sufficiently prosperous condition to admit of a further extension and embellishment of the grounds, and the shares have risen to a considerable premium. T. S.

FOREST VEGETATION IN SIAM (CHIN-INDIA).

## THE FRUIT GARDEN.

### PEARS ON THE QUINCE.

THE readers of THE GARDEN have to thank Mr. John Scott for giving them his experience of Pears grown on the Quince stock. The following do not appear in his list, but I have found them take readily on the Quince, and most of them to yield good crops and make healthy wood, viz.:—Beurré d'Arcenberg, Easter Beurré, Doyenné Buissoch, Josephine de Malines, Louise Bonne of Jersey, Marie Louise d'Uccle, Soldat d'Esperen, and Winter Nelis. Most of these are well known Pears, the Doyenné perhaps the least so, but it is a sort that has excellent qualities to recommend it, size, flavour, beauty, great productiveness, and what is somewhat remarkable, the foliage, like that of the American Creeper, turns to a deep red before the leaves fall. The Quince stock, as is well known, tends greatly to hasten the period of productiveness, but it also, in some instances, improves the quality of the fruit. Mr. Rivers long ago pointed out the second in my list as a remarkable instance of a Pear improved and altered in flavour by being grafted on the Quince stock. I should have added to my list the Orpheline d'Enghien, but I believe it is the same as Mr. Scott's Soldat Laborer, an excellent Pear, and one that ought to be in every collection. Of the White Thorn as a stock for Pears, my experience is confined to two only—the Jargonelle, which thrives upon it, and the Josephine de Malines, which I have found to die in the second or third year after grafting. Perhaps among your correspondents one may be found who could give some information respecting the White Thorn, stating the sorts that do best when grafted on it, and the character of soil and climate where Pears so grafted would be likely to thrive.

B. S.

### PEARS.

THE numerous varieties of Pears are usually grafted on either Quince or Pear stocks. When grafted on the Quince, the Pear succeeds particularly well in deep moist sandy loams. When grafted on the Pear, it will also do best in this kind of soil, but at the same time it has the advantage of doing well in almost any other, including very light soils. On the Quince we have not so long to wait for the fruit, and they are finer and better; on the Pear it is less difficult of culture and lives longer. On soils, therefore, which are not so

Young standard Pear-trees.

favourable to the Quince, we might use both kinds with advantage, planting Quince and Pear stocks alternately; and so, while waiting until the latter came into bearing, we should obtain crops from the former; and later on, when the trees on the Pear stocks should have come into full bearing, we could remove the others on the Quince.

Even under unfavourable conditions, the grafts on the Quince, if manured and well mulched every spring, might last for 10 or 15 years. The Pear-tree adapts itself to every form of training; those most commonly employed are: the standard, the pyramid or cone, the column, the palmette, the horizontal cordon, and sometimes the oblique cordon: on each of which forms we shall say a word or two.

**Standards.**—In gardens, especially those of small size, standards are seldom planted; they are generally reserved for orchards in the open country. If, however, you have ground to spare, and can devote a portion to them, without injuring the other trees or shading them too much, and without deranging the general plan or spoiling the appearance of your garden, it would be well to plant a number of the most select varieties; they will at a future time liberally indemnify the planter for any sacrifice of space which he may have made for them. As for the farmer, who is not pressed for room, we do not merely advise him to plant them, but enjoin him to do so. Properly speaking, standard Pear trees do not require pruning; every winter the centre of the tree should be cleared of any branches that are too crowded, and that is all, to let sun and air have free circulation. When the soil is adapted for the Quince stock, and well-selected, fertile, and sound-wooded varieties have been planted, the result is splendid crops of fruit, almost without pruning or training—almost without labour of any kind. At the time of planting, each tree should be fastened to a strong stake, which should be somewhat longer than the tree, otherwise the wind, as it sways the tree about, would rub it against the top of the stake, and thereby, especially when the fastenings began to loosen, cause wounds. We may also give the Pear tree the form of the pyramid or cone, which is, indeed, natural to some varieties.

**Pyramids.**—The pyramid or cone form is in high repute; it is a

Pyramid Pear-tree.

very ornamental form, and well calculated for securing a good crop. A fine strong pyramid, well-pruned, symmetrical and thriving, certainly is a handsome object. Like all the other forms which we are about to consider, the pyramid requires pruning more or less. With respect to the annual growth which we wish our young trees to make, it is wise not to desire too much; from five to seven main branches per annum is the most that we should allow. One remark on this subject: when laying out these branches for the next year's growth, we generally prune above and close to the bud which is intended to continue the branch, leaving a small spur afterwards as the bud pushes. In order both to strengthen it and give it the direction which we wish it to take, a support or splint is attached to it. This is a complicated operation; a better way is, instead of cutting close to the bud, to leave a long spur (say 4 inches), from which the buds are to be removed; to this the shoot is afterwards tied, and when it is sufficiently grown to maintain itself in the desired position, the spur can be cut off altogether, there being no further occasion for it.

It is a mistake to prune strong-growing sorts too closely, especially those on Pear stocks, because the circulation of the sap being thereby confined to a more limited space, it will have a tendency to produce strong wood where it is not wanted. It will, therefore, be best in pruning to use a judicious moderation. It is also a mistake to cut the lateral branches too short, because, the flow of the sap being

thereby restricted to the stem, will cause the production of overgrown leading shoots. It is equally wrong to allow these branches to grow too long, as this impoverishes the stem and retards the due growth of the leading shoot. In both cases the trees seldom bear well, for want of a proper balancing of the parts, and both extremes must be avoided. A well-proportioned pyramid should generally have a diameter two-thirds of its height. If, however well-proportioned, a pyramid on the Pear-stock should prove unproductive, it may be brought into good bearing by leaving it unpruned for a few years. There are also other methods: for example, making a circular incision in the bark at the bottom of the stem nearly half an inch wide, which must be kept open; otherwise, if allowed to close up, the tree will push more vigorously than before. Root-pruning will also produce the desired effect. It is wise to take advantage of everything, and we may turn the superabundant vigour of our trees to good account, by grafting them with fruit-buds, which will bear the following year, and produce fine fruits.

**Columnar Trees.**—The columnar form has this to recommend it, that it is easy to establish, and allows of a greater number of varieties being grown in a given space. The stem in this case is like a simple branch furnished with fruiting spurs. These are pruned above a rudimentary bud or eye; and as for the stem, that is allowed to grow as tall as the vigour of the tree will permit, unless you are afraid you will not find a ladder long enough to reach to the top. Trained in columnar fashion, Pear trees do not present a very graceful appearance, but the form has so many advantages, that we cannot avoid recommending it; they are easily managed, occupy very little space, bear plentifully, and do not present a large surface to the winds; all this deserves to be taken into account. It is hardly necessary to remark that the Pear grafted on the Quince is exclusively adapted for this form; those on Pear-stocks would be too vigorous, unless planted in a particularly poor and dry soil. Another advantage of the columnar form is that it is admirably suited for those kinds which, possessing but little, or only a moderate amount of vigour, generally make but a poor show in any of the larger forms.

Columnar Pear-Tree.

**Palmette-trees.**—The palmette, with a single or double stem, is very much employed for trees against walls, or for espaliers. Trained either to the right or the left (mostly both ways at the same time), the side branches extend themselves in greater or less number, according to the vigour of the tree.

Single-stemmed Palmette.

The palmette is easily formed in the following manner. About one foot from the graft, the young tree is cut off above three good buds—one on each side to form the first two lateral branches, and one above to continue the main axis. This last, when it has grown, is staked; and we must be careful of it, for it has to furnish in its turn another series of three buds, at a distance of 10 to 12 inches

from the first three, and which will be treated in the same manner. If the buds happen not to be in the desired position, a slight twisting of the branch, before the wood has ripened, will give them the proper direction. Should a bud be destroyed by any accident, a bud inserted in its place, in July or the beginning of August, will repair the damage.

Double-stemmed Palmette.

With very vigorous subjects on strong stocks, we may even gain time, as with them we may form two series of branches instead of one in the same year. As soon as the young branch begins to pass into the woody state, make circular incisions above two buds of the lower series, and you are sure to succeed; these incisions, of course, should be made while the tree is in leaf. This process is but little known, and is a most useful one. In training, it is always better to train the lateral branches a little obliquely, at least for the first few years; by degrees they can be brought to their final horizontal position. A great improvement has been for some years made in the training of the palmette; this consists in bending the ends of the branches upwards, and has received the title of Palmette-Verrier, from the name of one who did not invent it, but first applied it extensively and recommended it so highly that his numerous pupils gave to the system, previously without a name, that of its zealous propagator. We cannot, in fact, speak too highly of this form; for the palmette, it is the form of all others. The vertical direction, in drawing the sap to the ends of the branches, neutralizes the bad

Palmette-Verrier, with cordon in front.

effects of the horizontal position, which tends to encourage a sluggishness in the flow of the sap; it is also in accordance with Nature, in which we generally find the ends of branches inclined to the vertical direction.

What we have just said has reference to the palmette with a single stem, but the same treatment will apply also to the double-stemmed form. Cut the tree to within about 4 inches from the graft, get two branches to run in the required direction, operate on each of these afterwards, so as to obtain lateral branches; observe that between the two stems a space must be left of from 10 to 12 inches, according to the strength of the subjects.

For tying the branches get some laths split, or, better, sawn; place them in the direction of the branches, and fasten them with osier twigs to the trellis or wires previously arranged along the walls or in the lines of espaliers. We do not disapprove of fastening with shreds if the walls are in sufficiently good condition for that purpose, but training on wires is the best plan. In concluding our remarks on the Palmette-Verrier, we may observe that, when trained with a few series of branches, the form is thoroughly good for varieties that

do not possess much vigour of growth; when properly managed, nothing is more pleasing or more productive than small trees thus trained.

**Horizontal Cordons.**—This form, trained along wires, is also most suitable for varieties of feeble growth; the branches being few, and close to the ground, the fruits feel the good effects of the favourable position and become very fine. It is an excellent way of cultivating any kinds of which the fruit does not do well in the open air, such as the Brown Beurre, St. Germain, and others.

There are two ways of forming the horizontal cordon; the first is by means of a graft of one year's growth bent at the height which is desired for the cordon; and that the curve may not produce an effect disagreeable to the eye, it is brought almost to a right angle, by fastening the young stem firmly to a board driven into the ground until the upper end of the stem is brought nearly to a level with the place where the curve is made. This should be done carefully, and when the sap is ascending, to avoid as much as possible the chance of fracture. The second and surer method is to cut the young tree. In cutting, a spur is left by which the stem may be fastened to the wire. It is preferable to train these little trees right and left; it is just as easy as in one direction, and looks much better. On sloping ground, however, we should use the single cordon only. Nothing is more simple than this form, and yet we seldom see trees well trained as horizontal cordons; this is because they are generally planted too closely together, because a bad system of pinching is employed, and moreover, because they are almost always too closely pruned, whereas the ends of the branches should be merely trimmed. During the first three months' growth, and in proportion as they develop themselves, the young shoots should always be pinched short, and while they are still in a very herbaceous condition; this is indispensable. The sap, as is well-known, is constantly drawn up by the extremities, but these extremities not having, so to speak, been pruned, the shoots do not acquire any inordinate development, and speedily produce fruit-buds. Two or three years after planting, the pruning should be limited to shortening the extremities and removing the superfluous fruit-buds, of which it will be sufficient to leave two on each shoot, and

Horizontal Cordon, formed with two shoots.

be particular that these are the two nearest the main branch. Fourteen inches from the ground is the proper height for the branches of cordon Pears. Fasten them to the wire attached to iron or wooden posts placed at each end of the line. If you want to have these posts firm, bury them to the depth of about 20 inches, and let each have a stout jamb with the lower end resting on a flat stone or brick placed obliquely in the ground—any other props are unnecessary and often ugly—and let the posts not be of so great dimensions as to offend the eye. It is to be observed that after a few years, when the trees have become strong, instead of being supported by the wire, it is they that support it.

One concluding observation. We have said that almost everywhere trees that are intended for horizontal cordons are planted too closely together; this is one of the causes of failure. We recommend a distance of 10 feet as the minimum; at a later period it will be necessary to increase this distance to 20 feet, by removing every second tree; the subjects thus removed and taken up with care can be utilised elsewhere.

**Oblique Cordons.**—This form, which is not without its drawbacks, may be employed with advantage on sloping positions; in this case the tree must be trained in the direction of the slope. An oblique cordon is formed by cutting down a young tree, planted upright in the usual way, to about 8 inches from the graft. A single shoot is retained and fastened at an angle of 60 degrees; during the following year this angle is gradually reduced to 45 degrees. We might, indeed, at the outset, fasten it permanently at any angle, and not cut it so short, but it is much better to follow the method we have just indicated. What has been said refers to the single form, that is, with one branch; with the double form we proceed in the same manner, with the exception that after the first cutting we retain two shoots instead of one; the first, which is nearest the end, is to continue the main axis; the second will form the lower branch. The following year we cut the leading shoot at the distance of a foot from the former cutting, and retain only a single shoot to form the upper branch. The oblique form is faulty in this respect, that, in consequence of the sloping direction, the branches that are produced on the lower side are less profitable than those that spring from the upper, for want of being properly balanced for an equable flow of the sap.

## DOUBLE GLAZING FRUIT HOUSES.

I have tried this system of glazing on a Melon house and cutting frame, and have been somewhat startled with the result, which, to tell the truth, I might have foreseen. True, I found the night temperature could be kept up more steadily and with less fuel, but I found also that the sun's influence was scarcely felt during the day—had hardly found power, in fact, to raise the temperature of the house sufficiently to admit of proper ventilation—and so we had to fire up during the day instead of the night, to get the temperature high enough. Besides the continually saturated atmosphere was found to be highly injurious to the Melons, and positively destructive in the cutting frame, for the cuttings never got dry day nor night, unless the sashes were pushed well down, and then the cure was as bad as the disease. In the end I was compelled to take out one set of panes, and return to the old though somewhat inconvenient plan of covering the cuttings at night with a temporary glass shade or bell glasses, which were taken off again during the day, and we had no more trouble. The duplicate panes were also taken out of the Melon house sashes with the same result, though the Melons for a while were found to be so tender in the foliage, after growing in such a close atmosphere, as to require constant shading for a bit; but they soon recovered. Such has been the experience of one who started with great expectations of the system, and gave it a favourable trial. I am perfectly certain that, were our early vineries double glazed, the hottest April or May sun would never raise the internal temperature high enough to allow the necessary ventilation without a deal of assistance from fire heat. I would therefore not recommend anyone to incur the expense of double roofs without due consideration, and I shall be surprised to learn that the experience of others who have tried the plan does not agree with mine, so far as fruit culture is concerned at least.

J. S. W.

**Fruit Crops in North Nottinghamshire.**—On the night of the 19th and morning of the 20th, the frost in this district proved nearly as destructive to some kinds of hardy fruits as it did about the same time last year. Currants and Gooseberries have suffered most; the young fruit on the tops of the bushes, unprotected by the foliage, seemed as if scalded, and a brisk wind on the 23rd shook them to the ground in quantities. There will still, however, be a fair crop saved, for I have never seen these fruits set so thickly or their foliage look healthier than they do this year. The flowers of all the early kinds of Strawberries that had opened are blackened in the centre, and of course will prove abortive; but later kinds promise to produce good crops. Apples, being much later in flowering than last year, have escaped, and it is to be hoped that they are now out of danger. Pears, both on walls and standards, have set well, and there is a good prospect as regards the Cherry crop. Plums, however, are thin, both on walls and in orchards. Some sorts of Apricots showed at the blooming time a great paucity of blossom—the Kaisha being the only variety with me that has borne full crops for these last two years. The thermometer registered here on the morning of the 20th 2° of frost, and on the Grass 4°; we have, therefore, fared better, apparently, in the Midlands than in the Southern Counties.—WILLIAM TILLERY, *Welbeck, Worksop.*

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Woollen Rags as a Manure for Fruit Trees.**—M. Jacquemyus, in a recent number of the *Bulletin d'Arboriculture de Belgique*, states that he has produced a splendid growth in some fruit trees planted in a poor soil, by placing from 20 to 30 lbs. of woollen rags about the roots of each tree. These rags are a slowly-acting manure, rich in nitrogen, and in the case of the fruit-trees alluded to, effected most satisfactory results.

**Sweet Apples.**—With reference to your correspondent's inquiries on this subject, I beg to state that we have a large number of Apples in which the sugar greatly preponderates over the acid. We classify Apples into Summer, Fall, and Winter kinds, and subdivide each of these into sweet and sour. You doubtless have sweet varieties. Here they are used for baking, for cider-making, and for stock-feeding. Baked Apples and milk are regarded as one of the farmer's luxuries.—GEO. THURBER, *New York.*

**Grape colouring.**—It is a well-known fact that however large the bunches of Grapes or individual berries may be, without fine colour they are of little value. One of the most important points in reference to colouring Grapes, is to allow the stems to grow freely, after the final thinning. If the leaves half hide the bunches, so much the better. I picked up this hint at Coleorton, which is a sufficient guarantee of the excellence of the plan, as I consider Mr. Henderson to be the best cultivator with whom I am acquainted, for putting the finishing touch on Grapes.—R. GILBERT, *Burgley Gardens.*

**Cropping Fruit Tree Borders.**—May Strawberries be planted on fruit-tree borders? Some say they may; and others recommend me not to put such a soil-exhausting crop near my wall trees.—LYDIA. [We do not consider cropping fruit-tree borders with Strawberries good gardening—quite the contrary. Indeed many gardeners are against cropping them at all, but this we think is carrying the thing to the opposite extreme, as it is very rare that borders can be disposed with. Provided they are well manured, Lettuces and similar dwarf crops may be grown without injury to the fruit trees, but in no case should vegetables of any description be sown or planted nearer than 1 foot from the stem.]

## STATELY ARCHITECTURE NEAR WATER.

THE design engraved below is one of those stately architectural compositions in the country mansion category for which the Barrys (father and son) have become celebrated. There can be no doubt that the present noble design, if carried out in its integrity, will form a very magnificent object in the situation for which it is intended, and that its close proximity to the lake, in which its highly enriched *façade* will be reflected, must necessarily enhance its importance very greatly, and seem to impart to it a veritable *raison d'être* in the surrounding landscape. How much would the palatial magnificence of Versailles lose if the numerous pieces of artificial water which have been contrived there, at vast expense, were removed! The natural landscape, originally so arid and uninteresting, is magnificently lighted up by those watery mirrors, in which portions of the great palace, and whole crowds of the countless statues of its gardens, are so picturesquely reflected. In nearly all the celebrated French châteaux, from Fontaine-

production of lakes, at a considerable distance from the residence, and intended to group and combine in effect with foliage rather than with buildings. Our engraving of Mr. Barry's design for the new mansion at Clumber—and which we reproduce from the "Life and Works of Sir Charles Barry"—the effect of which, on the banks of the lake, is so highly successful, may serve as a hint for the production of similar effects in other situations. H. N. H.

**Land Formed by Marine Vegetation.**—The influence of gregarious marine plants in changing the form and increasing the extent of coast, which is visible in the islands of the Indian Ocean, is especially noticeable on the east coast of Sumatra, on account of the adaptation of the shore in its shape and nature to the propagation and growth of Rhizophoreæ (the Mangroves), as well as by reason of the luxuriant growth of vegetation in those regions. The whole coast for miles into the interior presents an unbroken, uninhabitable green flat, and the increase in depth of the water is very gradual, as is usual on the coasts of Indian islands but little

Stately architecture and terraced garden near water.

bleau to Chambord, water, of more or less extent, forms a chief and always an attractive feature in the scene. At some of the lesser of the well-known French châteaux nothing more than a broad moat exists; but, remove that moat, and carry the turf of the park close up to the stately rampart or terrace, and half the charm of the scene, even of the building itself, would be destroyed. Even the poor architecture of Buckingham Palace gains very considerably from being seen across the canal-like piece of water that is, with the exception of a few fine old trees, almost the only attraction of St. James's Park.

The horticulturist, in producing his best effects, has, in fact, as much to do with the introduction of water where it is absent, as with the disposition of his slopes of earth and their plantation with suitable trees. This, as a general principle, is so widely acknowledged as to be almost a truism; but the study of the effects that may be produced by the close proximity of water to important buildings of a palatial class has not been either so skilfully or so frequently attended to as that of the

above the sea level. The gradual transition from sea to land is very manifest. The earliest evidence of land is the appearance, especially at high tide, of scattered tips of the lower orders of marine plants, projecting above the water like blades of Grass in flooded meadow land. These belong, for the most part, to the Rhizophoreæ, more particularly the genera *Rhizophora*, *Kauldia*, *Bruguiera*, and *Ceriops*, so remarkable for their form and mode of growth. Their favourite habitat is a marshy shore, free from surf, and not flooded at high tide. They are shrubs rather than trees, from 5 to 25 feet high. The seed germinates while attached to the branch, and only separates when the rootlets have penetrated the slimy soil, and the young plant has strength enough to withstand the action of the sea. The stock does not enter the earth, but rather rests upon a mass of roots, spreading out as they approach the ground, and with their ends fixed in it. During flood-tide the tips of the plants only may be visible, but the retiring tide displays the stems and interlacing roots, the latter crowded with mollusks, crustaceans, and fish, left in the slime upon them. This accumulation becomes higher and firmer, and, finally, as coast-land, is better

adapted to resist the action of the sea than if the plants had rooted in the soil. With the Rhizophoræ are found species of similar families; for example, of *Ægiceras*, *Climatandra*, and *Avicennia*. As the sea recedes, and these plants are no longer moistened, even at high tide, they die out, and are succeeded by others of different mode of growth.

## THE KITCHEN GARDEN.

### THE SHALLOT.

NATIVES of the warmer side of the Mediterranean region, Shallots of course do best in a warm position and in a light, fertile soil. The Shallot is one of our best and most wholesome vegetables, useful alike for soups, salads, and other purposes, and it makes one of our best pickles. It is, in short, in everyday use, both in the kitchen and in the pantry. There are certainly two varieties in cultivation, as will be seen by the illustrations given at page 41, vol. i., and of these the light-coloured one is the kind mostly sought for for culinary purposes, but it is not so heavy a cropper as the dark-coloured Russian variety, and it is also more subject to canker and mildew. The dark hardy Russian kind is a heavy cropper. In order to grow Shallots well, and free from disease, never apply fresh manure to the ground on which they are to be grown. In autumn or early in winter, trench up and ridge a piece of ground for them that has been manured the previous season for some other crop, and fork it over in frosty weather, in order to get it sweet and well pulverised. Level it down, and plant the bulbs in February, but never by any means bury the bulbs too deep, nor plant them in very loose soil, for they are very subject to canker and mildew just when in full growth in May, if damp gets down between their partings or cloves; and on account of these attacks they are almost always scarce and dear. After levelling the ground, stretch a line at distances a foot apart: with one foot tread the ground along the line, only at planting time, from end to end; then just press the bulbs on the surface, and place a pinch of fine cinder ashes on them, to keep worms from them. In March, when the surface becomes dry and mellow, tread between the rows with both feet, so as to make the ground as firm as possible. This will raise the rows of bulbs a little above the general level; then just clear the loose earth away from the bulbs, which will now have pushed forth roots, with a hand or small hoe, so as to allow them, *i. e.*, the bulbs, to stand quite clear of the ground. Thus situated, disease or mildew, or failure, is scarcely possible: on the contrary, good, healthy, sound, firm crops are obtained. Plantations of Shallots may be made in October or March, but late in February or very early in March is the best season, and the crop may be taken up and stored whenever the leaves die down, or, if not then, in autumn. After being well dried, the roots should be hung in nets or laid thinly on shelves, or even hanked in an airy loft, or wherever the Onion crop is stored. J. B.

### TARRAGON.

THIS, a native of Siberia, is a very near ally of the Wormwood and Southernwood, though somewhat different in aspect, and very different in odour. It is an important old plant, that one always likes to see a few tufts of in a garden, and it is not at all difficult to grow. It is a hardy herbaceous perennial, but by no means so vigorous on some soils as its relatives before named. We have always noticed it vigorous and healthy on a light, warm soil, or one with thorough drainage, and slow-growing and almost delicate on stiff, clayey ones. It occasionally perishes from severe cold, and probably oftener from too much wet at the root. If we wished to preserve a few stools of it for a long time, we should put it on a slightly raised border under a south wall; but, as in ordinary cultivation such expedients are not resorted to, it is better to give it a well-drained spot in the herb ground, and make a fresh plantation every year, or every second year. It is often surprising to see what a good effect raising the earth from 6 inches to a foot above the level of the spot has upon many things that happen to be a little tender in this climate. We have no doubt that by raising the soil thus, by the aid of a

few burrs or stones, Tarragon would do far better on cold, wet soils, where on the ordinary level it is rather delicate. When just coming into bloom is the best time for picking it for placing in vinegar or making Tarragon vinegar, and it should be gathered when quite dry, as also for drying for winter use; but young Tarragon can be obtained most months of the year by pulling the young shoots in April when about 3 inches above ground, with an inch or two of underground shoot or root to them, and planting them 3 inches apart in boxes, pans, or garden pots, and standing them in the shade all the summer. The pots, &c., will get full of roots by autumn, and be in readiness to place in a little heat in succession all the following winter and early spring months, and whilst young and crisp it is in much request in many families. A succession of young fresh shoots is always obtainable out-of-doors by methodically cutting it daily for use, or, if not, cut part of the bed once a fortnight. Tarragon always does best on a sweet, healthy, pulverised soil, and planted in April, by pulling the young shoots with a bit of underground root as above described, and dibbling them in a foot apart each way, the ground will get filled by autumn, when the stems should be cut off when ripe and decaying on the approach of frost. The beds should then be dressed with old decayed Mushroom dung, light decaying old hot-bed linings, or half decayed leaf-mould, about 2 inches deep, in order to secure it from the winter frost; when not thus attended to, I have seen it entirely killed, or very much weakened by severe frost. By having a spot planted in various aspects it may be procured in succession, and very good and young a great part of the season. A hand-glass placed over some on a south border in the early part of the year will start it into early growth. It is liable to canker on wet cold shaded ground, and to be attacked by mildew both at root and branch on shallow hot soils.

JAMES BARNES.

### THE HERB GARDEN.

THE culture of herbs is one of those things that are generally neglected, unless a special place is set apart for them. To have a place for everything is the likeliest means of having everything in its place. Form an herb garden, and you are well nigh certain to fill it with plants. Scatter them here, there, and everywhere, and the chances are that "out of sight out of mind" will be speedily verified, and that when the herbs are required they will be found wanting. There is likewise a great saving of time in growing all the herbs together; one always knows where to go for them, and several are mostly wanted together. The herb garden is likewise a pretty feature in itself. A series of beds, say 6 feet long and a yard wide, parted with tiny walks a foot broad, has a neat, orderly appearance. But the chief advantage of having a garden of herbs is that, when disposed thus, they are almost sure to receive the requisite degree of attention. When each has a bed, we like to see each bed filled with healthy plants. Some herbs, such as the Mints, on most soils grow like weeds. Others, such as Fennel and Tarragon, are shy growers, and winter badly in many gardens; others again, such as golden, common, and Lemon Thyme, and especially Penny Royal, require frequent removal. The last should be replanted every autumn. Large plants have their crowns frosted out in winter, and the whole plant frequently perishes. Small rooted pieces from the extremities of the growing shoots planted in October will bear any amount of frost with impunity. Hyssop, Winter Savory, winter Marjoram, and Sage do not need renewal so frequently; and the bitter or strongly aromatic herbs, such as Rue, Horshound, Rosemary, Tansy, Wormwood, &c., are equally hardy, and even longer-lived. Feverfew makes a good edging to the other beds, and Lavender is best grown in the shrubbery. Such large herbs as Angelica and Caraway, and even Borage, should be grown in rows near to Rhubarb, Globe Artichokes, or other strong vegetables. Several beds should likewise be retained for growing such annual herbs as Basil, Marjoram, Savory, Chervil, Parslane, Pot Marigold, &c. Hot or bitter plants for eating green as relishes, or for salads, such as Mustard, Cresses of various kinds, Pimpernel, Chives, green Onions, Radishes, should also be grown in the herb garden. Various plants, such as Curled Malloes, and others for garnishing, might find a place in the herb garden. Parsley is too important a crop to be grown in the herb garden; it does best in deeply-trenched, rich land. Sow in drills 2 feet asunder, or in a single drill, on the verge of other crops. Thin the plants to 6 inches or a foot asunder, and, with liberal culture, one leaf of Parsley will well nigh garnish a ham. Q.

## ASPARAGUS CULTURE.

MR. BARNES' articles on this subject will, I hope, do good. I never pass through Covent Garden in the winter season without, as I look upon this picture and on that, a tingle of shame running through my veins as I compare our own poor spindly Asparagus with the sturdy examples of it which our neighbours the French send us. Why this should be, I cannot tell, except that our system of cultivation is at fault. A friend of mine at Birkenhead, a quarter of a century ago, grew good succulent Asparagus, four sticks of which weighed a pound, and in the early days of Frogmore, Mr. Ingram exhibited forced Asparagus sixteen to eighteen pounds the hundred. I am justified, however, I think, in saying that in neither case was it grown upon the root-pruning and banking-up systems. On the contrary, at Birkenhead, the ground was well manured and thoroughly trenched 2 feet deep, and 18 inches of thoroughly prepared compost was then carted on to it; the Asparagus was sown in single rows a yard apart, and the plants were thinned so as to stand a foot apart in the row. In addition to being mulched with rich manure in the autumn, the only cultivation which these beds received was a slight surface forking in the spring; also a slight sprinkling of salt and guano every fortnight on rainy days in the growing season, and they were kept free from weeds. Compare this with our market-garden treatment, which consists in sticking a sea-side plant on a dry bank, and we need not be surprised that London Asparagus is called "drumsticks," and that few people know the flavour of properly grown Asparagus. The only possible gain derivable from the London system of cultivation is a few days' earlier growth consequent on the daily earthing in of solar heat in the spring, and a little gain also in heat from the action of the sun's rays upon the sides of the beds. This may give a few hundreds of early "natural Grass;" but whether the gain is sufficient to cover the extra expense of cultivation is more than doubtful. Asparagus beds is a cultural misnomer; and where, for early forcing, it may be necessary to form beds, those should always have pigeon-holed repairing walls, so that the necessary heat may be given without the roots of the plants being injured. Thus managed, our forced Asparagns might, in a short time, be as good as that of the French, and of many of our own private gardens; but, as seen in our markets in the winter and early spring, it is simply a disgrace to the country.

A.

**Potato Disease—Cause and Effect.**—Originality on this subject we thought had been worn out, but, according to a western contemporary—the *Exeter Flying Post*—there is yet something to learn on this interesting national question. A correspondent of that journal (Mr. John Bucksey, 8, St. Petrock's Terrace, Exeter), thus writes:—"I wish to bring under your notice the enclosed Oak galls. They show a mutation they have not shown heretofore. For many years the fly has eaten its way out, leaving a beautifully defined hole, now, on the contrary, the birds have attacked them, and to get the maggot torn the galls. My object is, first, to assert that these galls were not seen in England before the Potato disease, and that till recently birds had not attacked them; secondly, that this fly has been the cause of the Potato disease; thirdly, that the maggots contained in the galls heretofore having been destroyed there can be no flies of the kind this summer. Consequently, we shall have such a crop of Potatoes as we have not seen for twenty-eight years. Kindly put this in your paper, that it may induce others to give it attention and to hand to you for publication the result of their observations." [Oh!]

**Tomatoes.**—Early Tomatoes are still grown to some extent in New Jersey and Long Island, but each year during the last seven there has been a steady falling off in these districts, owing to the fact that the Tomatoes which are now planted by hundreds of acres around Charleston and Norfolk can be placed in Northern markets six weeks in advance of those produced nearer home, and so it happens that by the time the latter are ripe, even under the most skilful management, prices have fallen to 50 cents a basket at best, and with the probability that the last pickings will have to be sold at 15 cents a basket, or less. This is a very different state of affairs from what prevailed even ten years ago. Then the intelligent Tomato culturist in New Jersey was sure of getting 3 dollars a basket for the first and second week's picking, and wind out the last of the crop at not less than 50 cents a basket. At these prices, the Tomato was one of the most profitable crops for the market gardener, but now he can use his frames, and employ his time more advantageously.—*New York Tribune.*

**Horseradish Culture.**—Is the plan of growing this by placing a common round drain-tile with it, and set a couple of inches in the earth, filling the tile with fine earth, and planting a set near the top of the tile and 10 inches above the surface, sufficiently well known? Mr. Bradley, at Preston Hall, says it is an admirable plan; digging for the product is saved, and a fine clean stem is the result.

## GARDEN DESTROYERS.

## TOBACCO POWDER AS AN INSECTICIDE.

NUMBERS of new remedies for the destruction or prevention of insect pests have lately been introduced, with the merits of some of which I am not yet acquainted. Tobacco, however, in some form or other, has long been recognised as one of the best things for destroying all kinds of aphides, especially out of doors. It is long since I first saw snuff used for destroying both green and black fly. An old enthusiastic gardening friend, who was fond of a pinch of snuff, would often take out his box and dust some of its contents over his insect enemies whenever he saw them on his favourite plants. It was at that time too expensive for general application; but it gave the man who regularly carried a box in his pocket many an opportunity, at this season of the year, of taking signal and prompt vengeance upon his enemies. In destroying insects, the old maxim, "A stitich in time saves nine," holds more than good; for, when aphides have thoroughly established themselves on a plant or tree, it is a difficult matter to destroy them all. If, on the first appearance of insects, a puff of powder is dashed among them, it settles them directly; and a good syringing in three or four hours afterwards washes off both snuff and dead bodies. A man armed with a distributor and a supply of dry powder will in a short time go over a large collection of Roses or a number of wall trees; and, as far as my experience goes, I consider that the use of tobacco powder in the open air is better and cheaper than any dressing which I have hitherto used in a liquid form. It penetrates readily every portion of the tree, carrying destruction in its course; for it is astonishing how soon death ensues after the powder is sprinkled over them. The best time to apply it is when the trees are slightly damp, just before the dew clears off early in the morning; when the trees, however, are thoroughly charged with moisture, I do not think the powder is so effectual. The "distributor" which I use is a bottle-shaped india-rubber apparatus, which is taken in the palm of the hand, and, whenever pressure is applied, the powder is sent flying in a cloud of finely-divided particles in any direction the operator wishes. All nurserymen supply the powder in either small or large quantities.

E. HOBDAY.

*Ramsay Abbey.*

**Galvanised Wire and Woodlice.**—I use my galvanised wire seed guards for a novel purpose. They were originally bought as a protection to seeds from birds, and for this they answered very well, the meshes of the wire being sufficiently small to prevent birds from getting through to eat the seeds. When not in use in that way, I flatten and straighten them, and employ them as flower-pot stands, raising the corners a little above the level of the ground. Wire stands for plants have this advantage over those of a solid character, viz., that air can pass through the meshes. If flower-pots are allowed to stand long in one place, without being moved, damp stagnates under them, and woodlice breed amongst the drainage in the pots. These, if permitted to increase, do great damage to the plants. By using the wire stand, it is obvious that no moisture can accumulate under the pots. When the plants are watered, the superfluous wet runs off through the interstices, which soon become dry. Placing the pots on ashes and sand has been recommended, but galvanised wire is the best remedy. It has afforded me such satisfaction that I also use it for the bottoms of my cold garden frames. The weight of the pots is supported by little wooden stools, which I have had made expressly for this purpose; but where these cannot be had, empty flower-pots turned upside down, placed at the four corners, do very well.—F. H. B., *Camberwell.*

**The Upas Tree.**—Such a tree certainly exists in Java, but the tales that are told of its poisoning the air for hundreds of yards round, so that birds dare not approach it, that vegetation is destroyed beneath its branches, and that man cannot come near it with impunity, are perfectly ridiculous. To prove their absurdity, a friend of mine climbed up a Upas tree, and passed two hours in its branches, where he took his lunch and smoked a cigar. The tree, however, does contain poison, and the natives extract the sap, with which they rub their spears and kris blades; wounds inflicted with blades thus anointed are mortal. Such I believe to be the origin of the many fabulous stories that have passed from hand to hand, and from generation to generation, about the Upas tree of Java.—*J. Davidson.*

## WORK FOR THE WEEK. PRIVATE GARDENS.

**Flower Garden.**—Summer bedding out must now be completed, and injury from frost should be guarded against by means of evergreen boughs, mats, canvas, or other available material. Before filling the beds, have the Grass mown and the edges cut, or, where Box is used as an edging, it should be trimmed. Water well all plants when put out, and, when the planting of each bed is finished, its surface should be loosened or levelled, either with a hoe or rake, so as to give it a neat appearance. Dahlias, Hollyhocks, Gladioli, &c., may be planted nearest the shrubs and dwarfier plants, such as odds and ends from amongst the stock of bedding plants. Annuals and biennials may likewise be effectively employed here and there in front of them, *i.e.*, next the walk. Roses, now coming into bloom, will be benefited by occasional soakings of manure water.

**Plant Houses.**—In the warmer houses air must be admitted early and the houses shut up soon in the afternoon, shading being employed in all cases on bright days. A moist atmosphere and plenty of water at the root, a moderately high temperature and shade are at present necessary for the production of well developed young leaves and wood; pinching shoots in order to induce a stubby growth, and tying in climbing plants should also be practised. Seedlings and cuttings require potting now and again, an operation to which attention must be paid. Shading must now be used for greenhouses or conservatories, otherwise flowers will quickly shed their petals, and their colours will lose their brightness. All cool houses must be well ventilated, and even at night the sashes may be left a little open, but if the wind is likely to be troublesome, ganze or screen-wire sashes may be used as substitutes for the glass ones.

**Reserve Garden for Flowers.**—In every place of any considerable size there should be such a spot as this for the purpose of accommodating plants removed from the flower garden to make room for others, for supplying auxiliaries in case of failure, for propagating purposes, and for forwarding young plants. As good keeping in such a place may be questionable, it should be separated from the main garden by means of a hedge; and for this purpose Privet, owing to its rapid growth, answers well; but Beech, Hawthorn, Holly, Yew, and others may be, if necessary, employed for the same purpose, or a wooden fence or brick or stone wall may be used instead of a hedge. The soil, if possible, should be a good sandy loam, well enriched with decayed manure and leaf-mould, peat being likewise serviceable for some things. Bulbous plants removed from spring gardens should be planted here until their bulbs have become properly matured. Daisies, Alyssums, Hepaticas, Ajugas, &c., may likewise be lifted from beds that are to be planted with summer flowering plants, divided, and replanted in the reserve garden, shading them with evergreen boughs, and watering them well for a time. Annuals and biennials intended for seeding purposes should also be planted here, in order that their seeds may be carefully saved. Biennials, as a rule, may now be sown in small beds, either broadcast or in lines, so that they may be transplanted when fit to handle.

**Hardy Fruit Garden.**—Carefully disbud fruit trees on walls, and stop the strongest shoots, so as to induce an equal distribution of the sap. Pick off and destroy all blistered and curled leaves, and, if necessary, partially thin the fruits. Syringe daily with clean soft water, and if aphides be present, destroy them either by means of tobacco-water or dry powder applied by what is termed a "distributor." Use flowers of sulphur as a preventive of mildew, and fresh white Hellebore powder for the destruction of caterpillars on fruit bushes. Regulate the growth of lately-planted trees, and attend to the training of the shoots of young wall and espalier trees yet in nursery lines.

**Kitchen Garden.**—The late rains have had a good effect on Cabbages and other vegetables, all of which are now excellent. Cauliflowers under handlights are fit for use, and the supply of Broccoli has not yet become exhausted. Peas, too, are forming pods, and will be in time to take the place of Asparagus. Sow some Broccoli for spring use, and thin or prick out the latest sown Cauliflowers. Plant out Cabbages, Savoys, and Brussels Sprouts in deeply-worked well-manned soil. Tie up Cos Lettuces for blanching, transplant successive crops of them, and sow a few seeds in a moderately cool border. A few seeds of Beans and Peas may also still be sown to keep up a succession. Thin out Cardoons, if sown where they are intended to remain, if not, plant them out, and water them freely. Sow Spinach for succession, in some cool partially shaded position; by sowing it broadcast, and planting it out along with Cauliflower or some similar crop, it will be fit for use in a short time, and may be removed before any injury can be done to other crops. New Zealand Spinach, raised in frames, may now be planted out; in dry, hot, seasons it is a valuable substitute for ordinary Spinach. Thin out Carrots a little, Parsnips, Beet, Turnips, Salsafy, Scorzonera, Onions, &c., and keep them free from weeds, maintaining an open surface

amongst them. Earth up Potatoes, Peas, Beans, and Cabbages as they require it. Make occasional sowings of Radishes and small salads, and protect the seeds from birds, by means of wire or other nettings, or by mixing the seeds with red-lead, previously to sowing them. Transplant early spring-sown Leeks in lines from nine inches to a foot apart. Make another sowing of French Beans, and earth up and stake runner sorts. Prepare trenches for Celery, and plant out some of the earliest. Plant out Basil, Marjoram, and other herbs raised in frames. Plant out Tomatoes in warm positions, and also Vegetable Marrows under handlights. Sow Gherkins on warm borders, in lines 4 or 5 feet apart, leaving about 4 or 6 inches between the seeds.

## NURSERIES.

All odds and ends in the way of bedding plants may now be placed in frames or pits, and except in the case of the weakest and youngest a cool temperature is sufficient for them. Anything the stock of which is short must be increased, but a sufficient quantity of store plants should be retained. Seedlings of Violas, Pansies, Polyanthuses, Pentstemons, Anemones, if strong enough, may be planted out for autumn and spring sales. Of Corydalises, *Crambe cordifolia*, *Linum narbonense*, *Convolvulus althaeoides*, *Althea cannabina*, *Aquilegias* of different sorts, *Phytolacca decandra*, *Statice*, *Eucalyptuses*, and many other miscellaneous plants raised from seed, should be pricked off into pots or pans in a compost of peat, loam, and leaf-mould, in equal proportions, with a good admixture of sharp sand; a close frame or slightly heated pit is warm enough for them. The general stock of autumn-struck hard-wooded greenhouse plants may now be potted. Cuttings of Heaths, Epacris, &c., should now be put in, selecting the weakest growths for the purpose. Climbing plants, such as *Dipladenias*, *Echiteses*, *Allamandas*, *Passifloras*, *Bignonias*, *Cobea*, *Aristolochias*, where stowed closely together, are apt, now that growth has commenced in earnest, to become intertwined; they must, therefore, be gone over now and then, and tied into proper form. Syringe them well, and also water them freely. Seedlings of *Primula japonica* should be repotted and set in sheltered places out-of-doors; keep seed-pans containing this *Primula* in frames until the seed germinates. Rooted cuttings of *Vinca oenclata* should be potted and others shifted; they seldom look well when old. Cuttings of *Ixoras*, *Ficuses*, *Rhopalads*, *Cissuses*, *Passifloras*, *Aralias*, and other plants of similar kinds that are rooted, may be potted singly and still kept within the same frame inside the propagating pit or stove. *Dracenas* may yet be increased from roots, pieces of the stems, and racemes of flowers fertilised for seed. Such blooms as are produced early in the season are those commonly chosen for this purpose, as they have the full season before them for the maturation of their berries. Plants bearing seed should be elevated on inverted pots in a sunny part of the house, where their large clusters of red berries are extremely pretty. *Alocasias*, such as *Lovii*, *metallica*, and others, may be plunged in bottom heat, and have their crowns taken off for cuttings; shoots afterwards produced will also prove useful for the same purpose. Young plants of *Caladiums* in small pots should be shifted before the roots become cramped. *Achimenes*, if potted, may be propagated just like *Verbenas*, if the stock of them is short; where the roots have not yet been planted, they will be pushing young shoots, so that they had better be planted now as soon as possible. Pot off seedling *Begonias*, repot those raised from leaves last summer, and start into growth all dormant stools. Cuttings of *Pereskia* should be potted singly, *Cacti* may also be well watered, and increased by means of cuttings, offsets, or grafts. Place *Epiphyllums* in a moist, warm temperature, to form fresh growth; and set the several hardier kinds of *Cacti*, *Aloes*, and other succulents, in light and airy houses, or out of doors as soon as all danger from frost is over. *Gladioli* in pots may likewise be plunged in ashes out of doors, and such as are unsold may afterwards be turned out of their pots and planted in a rich border. Old plants of *Chrysanthemums* should be plunged out of doors in ashes, and young ones set in frames. Pot *Hollyhock* seedlings, and plant out cuttings of them when rooted. From *Agaves* and *Yuccas* remove the suckers; pot them in good loam and keep them for a time in a close pit. *Marantas*, such as *tubispatha*, and *Alocasias*, such as *Jenningsii*, should be divided, repotted, and started in a brisk heat. Place young plants of *Tillandsia Lindenii* that are in small pots inside of others two sizes larger, filling up the empty space with sphagnum. Palm seedlings still in the boxes should be potted singly and kept rather close for a time. Peg down the shoots of *Sonerila margaritacea*, so that they may root at the joints, and eventually be separated and potted singly. The variegated *Pandanus*, such as *javanicus* and *Veitchii*, produce shoots around their necks in abundance, and the more these are taken off for cuttings, the more the plants produce shoots, which when some inches long should be removed with a heel, and inserted singly in pots, which should be plunged in bottom heat under a handlight.

## SOCIETIES, EXHIBITIONS, &c.

### ALEXANDRA PARK.

On last Saturday, the 24th inst., the great inaugural flower-show was held here, under happy conditions. The weather was as fine as could have been desired, a pleasant breeze blowing over the hill. The effect of the plants arranged along the nave of the Palace, well broken up as they were by tall Palms, Tree Ferns, &c., was very good. Indeed, we have never seen the better evidence of the importance of such plants than was afforded by the plant-stages as seen from the galleries and various other points. Out of doors there were also great attractions, the clear day permitting the wide and beautiful views commanded by the palace on every side to be seen to full advantage.

**Stove and Greenhouse Plants.**—As a rule these were of superior merit, being large, well grown, and profusely flowered. In the class of sixteen distinct kinds, Mr. Baines was first, with excellent plants of *Aphelaxis macrantha rosea* and *purpurea*, *Azaleas*, Sir Charles Napier, *Iveryana* and *Stella*; *Dracophyllum gracile*, *Eriostemon nerifolium* and *E. cuspidatum*, *Boronia pinnata*, *Erica Cavendishii*, *E. tricolor* Wilsoni, and *E. ventricosa coccinea minor*; *Frausea confertiflora*, *Anthurium Scherzerianum*, *Dipladenia amabilis*, and *Ixora coccinea*. Mr. Donald, Leyton, was second, with a fine group, consisting of *Azaleas*, *Heaths*, a fine specimen of *Pimelea Hendersonii*, *Polygala Dalmaniana*, *Clerodendron Balfourii*, and others. Mr. G. Wheeler, Regent's Park, was third. In the nurserymen's class of twelve plants, Messrs. Jackson and Sons, Kingston, were first, with very fine specimens, including a massive plant of *Erica depressa multiflora*, *Acrophyllum venustum*, *Bougainvillea glabra*, *Rhododendron Gibsonii*, a magnificently bloomed *Stephanotis floribunda*, and others; Mr. B. S. Williams was second, with a wonderfully fine group, containing, amongst others, a finely bloomed plant of *Allamanda grandiflora*; and Mr. W. Cuthbert, Barnet, was third, with good plants, particularly a nice specimen of *Gompholobium polymorphum splendens*. In the amateurs' class of ten plants, Mr. Ward, Leyton, was first, with extremely well-grown specimens, amongst which were a magnificent *Statiea profusa*, a fine plant of *Adenandra fragrans*, and an excellent example of *Genetyllis Hookeri*. Mr. Johnson exhibited a good half dozen specimens, conspicuous among which were *Bougainvillea glabra* and *Pimelea amabilis*. In the nurserymen's class of half a dozen specimens, Mr. W. E. Dixon, Norwood Nursery, Beverley, was first, and Mr. G. Cooper, Derby, second. For the finest stove or greenhouse plant in flower, Mr. Baines was first, with a huge specimen of *Hedera macropoda* laden with flowers; Mr. Donald also showed a massive *Epacris* called *Eclipse*. For twelve fine-foliaged plants, Mr. Baines was first, with a wonderfully fine group, in which were immense plants of *Sarracenia flava* and of another variety of the same type, a large tubful of *Sarracenia purpurea*, fine specimens of *Theophrasta imperialis*, *Crotons*, *Ferns*, *Palms*, &c. The other successful competitors were Messrs. Wheeler, Tinzley, and Hill. Mr. B. S. Williams was first in the class of eight fine-foliaged plants, with fine specimens of *Livistona borbonica*, *Chamaerops humilis*, *Croton variegatum*, *Yucca aloifolia variegata*, *Dasylium plumosum*, *Encephalartos latifrons*, *Theophrasta imperialis*, and *Gleichenia semi-vestita*. Mr. W. E. Dixon was second, and Mr. W. Cuthbert third. For sixteen specimens—Dixon was second, and Mr. W. Cuthbert third. For eight foliage and eight flowering—Mr. G. Cooper was first, with fine specimens, including *heaths*, *Azaleas*, *Hedera macropoda*, *Acrophyllum venustum*, *Palms*, particularly a plant of *Phoenicophorium Seychellarum*, and others. In Mr. B. S. Williams' group, which was second, there were, amongst others, large plants of *Pandanus reflexus* and *Cycas revoluta*. Mr. W. E. Dixon was third.

**New Plants.**—Of these, prizes were offered for a dozen sent out in 1871-3, and also for half a dozen, the competitors in the one class being prevented from competing in the other. For twelve plants Messrs. Veitch and Sons were first with *Masdevallia Harryana*, bearing six flowers, *Odontoglossum vexillarium*, *Maranta Makoyana*, the fine *Aralia Veitchii*, *Dracaena imperialis* and *magnifica*, *Pandanus Veitchii*, *Paulinia thalictrifolia*, *Cypripedium Dominianum*, *Dieffenbachia Bausei*, *Kentia Forsteriana*, and *Croton Weismannii*. Mr. B. S. Williams was second, with plants of the handsome *Anthurium crystallinum*, *Dracaena Fraserii* and *metallica*, *Ixora Colei*, *Phyllotæmium Lindeni*, *Dæmonorops palembanica*, *Cyrtodeira fulgida*, and others. Messrs. Rollisson and Sons were third, with *Davallia Tyermanii*, *Veitchia Canterburyana*, *Dracaena lenticulosa*, *Pteris serulata Applebyana*, *Sempervivum spinosum*, and others similar to kinds already named. Mr. W. E. Dixon showed half a dozen nice plants, for which a first prize was awarded.

**Orchids.**—In the amateurs' class of a dozen plants, Mr. Cuthbert, Chase Park, Enfield, was first with a fine group consisting of *Cattleya Mossie*, *Oncidium ampliatum majus*, *Odontoglossum Alexandrae* (three varieties), *O. Pescatorei*, *Thunia Bensoniae*, bearing seven fine heads of bloom; *Anguloa Clowesii*, *Vanda tricolor*, *Phalenopsis Luddemaniana*, *Cologyne pandurata*, and a fine specimen of *Lycaste cruenta*. Mr. G. Wheeler was second. In the nurserymen's class of ten plants, Mr. B. S. Williams was first, with a splendid group, comprising *Calanthe veitchifolia* and with ten flower-spikes, *Cypripedium villosum*, *barbatum majus*, and *Aërides Fieldingii*, a beautiful variety of *Laelia purpurata* with four flower spikes, *Dendrobium Farmerii* bearing five good spikes of bloom, two varieties of *Vanda tricolor*, and a fine example of *Saccolabium retusum* with four flower spikes. Messrs. Jackson and Sons were second with a group of fine plants, particularly one of *Dendrobium infundibulum*. Messrs. Veitch and Sons exhibited a miscellaneous group of Orchids, which formed in themselves one of the most interesting features of the exhibition. Amongst them were different varieties of *Odontoglossum*

*Alexandrae*, a finely-flowered plant of *Aërides Fieldingii*, *Cypripedium* of different kinds, particularly *C. Lowii*, *Veitchii*, *caudatum*, *Dominii*, *Stonei*, and its variety *platytenium*, the last an exquisite kind raised by Mr. Day, of Tottenham. The same collection also contained plants of *Masdevallia Harryana*, *Anguloa Clowesii*, *Ruckerii*, and *uniflora superba*, a deeply-spotted variety of *Odontoglossum nebulosum*, and a plant of the lovely *O. vexillarium* with four flower spikes, three of which bore two flowers each, and another one four flowers; a little plant of *Utricularia montana*, a nicely-bloomed example of *Dendrobium crystallinum*, and one of *D. Devonianum* with some five dozen blooms on a spike. In addition to these there were also plants of *Colax jugosus*, *Saccolabium curvifolium*, *Phalenopsis grandiflora*, and the little *P. Parishii*, various *Trichopiliis*, and similar plants.

**Palms.**—These, as a rule, were excellent. Mr. B. S. Williams, Messrs. Rollisson, and Messrs. Jackson were the most successful exhibitors of them; in the amateurs' class of three kinds, Mr. Douglas, Worcester House, was first, with good examples of *Latania borbonica*, *Hypophorbe Verschaffeltii*, and *Pritchardia Martii*; Mr. G. Wheeler was second.

**Cycads, Pandanus, Dracaenas, Yuccas, Crotons.**—Mr. W. E. Dixon was first for Cycads, with good plants of *Encephalartos Lehmanni*, *trispinosus*, *Ghelinekii*, and *villosus*, *Cycas revoluta*, and *Dion edule*; Mr. B. S. Williams was second, with a somewhat similar group. Mr. Williams and Messrs. Rollisson also competed in the class confined to a pair of Cycads. With a pair of *Pandanus* Mr. G. Cooper was first, with two fine specimens of *P. utilis*. Mr. Williams, Messrs. Rollisson, Mr. Wheeler, and Mr. J. Douglas contributed good specimens of *Dracaenas*, some of which were unusually tall and were surmounted by a fine tuft of leaves. Mr. Williams was also first in the class of ten *Dracaenas* and *Cordylines*, with some good specimens of the green-leaved kinds. He was likewise first for a pair of *Yuccas*, and also for a pair of *Beaucarneas*. In the amateurs' class for the best pair of *Crotons*, Mr. S. Johnson was first, with specimens of *C. pictum* and *variegatum*; and Mr. G. Cooper occupied a similar position in the nurserymen's class with *C. angustifolium* and *variegatum*.

**Ferns.**—These were well represented. In the amateurs' class of twelve kinds, Mr. Baines was first, with grand masses of *Davallia bullata* and *dissecta*, *Todea superba*, *Gleichenia Spelunca* and *rupestris*, *Lomaria gibba* and *cycaedifolia*, *Cibotium princeps*, *Cyathea dealbata* and *medullaris*, *Dicksonia antarctica*, and *D. squarrosa*. J. M. Shuttleworth, Esq., was second, Mr. Donald third, and Mr. W. Cuthbert fourth. In the nurserymen's class, Mr. B. S. Williams was first, with good specimens of *Platyceerium grande* and *alcicornis*, *Todea intermedia* and *africana*, *Adiantum Farleyense*, *Gleichenia flabellata*, *Cibotium regale*, and others. Mr. W. E. Dixon was second, with a good group, conspicuous in which was a fine plant of *Adiantum Farleyense*. In the class of six specimens, Mr. Shuttleworth was first, Mr. S. Johnson second, and Mr. G. Wheeler third. Mr. Shuttleworth was likewise first for six specimens of *Gleichenias*, and also for twenty-four kinds of hardy Ferns, a class in which Messrs. Jackson were second. For half a dozen specimens of *Adiantums*, Mr. Douglas was the most successful exhibitor, with good examples of *tenerum*, *cuneatum*, *concinnum latum*, *formosum*, *macrophyllum*, and *trapeziforme*. Mr. B. S. Williams was first, for the finest Tree Fern, with a noble plant of *Dicksonia antarctica*, having a trunk nearly 2 feet through, surmounted by a noble head of fine fronds; Messrs. Rollisson also received a first prize for a splendid specimen of *Cyathea medullaris*, the trunk of which was some 10 inches in diameter. Messrs. Jackson were likewise contributors of Tree Ferns.

**Heaths.**—These consisted chiefly of kinds alluded to in previous reports. In the amateurs' class of eight specimens, Mr. Ward was first with *Erica Candolleana*, *Caveudishii*, *ventricosa magnifica*, *v. coccinea*, *tricolor elegans*, *t. impressa*, *candidissima*, and *eximia superba*. Mr. G. Wheeler was second. In the nurserymen's class of eight kinds, Messrs. Jackson were first, with fine specimens of *E. depressa*, *tricolor speciosa*, *t. Wilsoni*, *t. superba*, *favoides elegans*, *affinis*, *Victoria*, and *ventricosa coccinea minor*. Mr. B. S. Williams was second in this class.

**Agaves.**—Of these good groups were exhibited, consisting of plants of medium size. Mr. Croucher, gardener to J. T. Peacock, Esq., was first in the amateurs' class of ten plants, and Dr. Kellock, Stamford Hill, second. Mr. B. S. Williams was first in the nurserymen's class, with a fine group, including *Agave potatorum*, *filifera densa*, *Regeli latifolia*, *gemmiflora filifera*, *Verschaffeltii*, *densiflora*, *Gliesbreghtii obscura*, *applanata*, &c.

**Orange Trees, Rhododendrons, and Azaleas.**—Mr. B. S. Williams showed a good Orange tree, and specimens of *Rhododendrons*, and other groups of which were likewise exhibited. In the class of half a dozen *Azaleas* in flower, Mr. G. Wheeler was first in the amateurs' class, and Messrs. Jackson in the nurserymen's with *Duc de Nassau*, *Criterion*, *Roi Leopold*, *variegata*, *Sir C. Napier*, and *Alexander II.* Mr. C. Turner, of Slough, was second. Mr. Turner was first for six standard *Azaleas*, with some very finely flowered plants, and likewise first in the nurserymen's class for fifteen distinct kinds, with small but well bloomed plants.

**Roses, Laurustinuses, and Bays.**—Of these some good specimens were exhibited. In the class of twelve *Roses* in pots, Messrs. Paul & Son were first, with remarkably fine plants, among which were *Duke of Edinburgh*, *Madame Margottin*, *Anna Alexieff*, *President*, *Camille Bernardin*, *Marechal Vaillant*, *Charles Lawson*, *Souvenir d'un Ami*, *Madame Villermoz*, *Madame Victor Verdier*, *Victor Verdier*, and *Paul Verdier*; Mr. Turner was second, with a very fine dozen of *Roses*, and first for twenty distinct kinds; Messrs. Paul & Son being second. Messrs. Paul & Son likewise exhibited a large group of cut blooms, all remarkably large, fresh, and fine;

and Mr. Soder, Brentwood Lodge, showed a stand of blooms of Marechal Niel. Mr. Turner showed a pair of standard Laurustinuses, and Messrs. Veitch & Sons, and Mr. B. S. Williams, pairs of very fine Bay trees, for which they received first and second prizes respectively.

**Pelargoniums and Calceolarias.**—Both these were remarkably fine. In the nurserymen's class of eight show Pelargoniums, Messrs. Dobson were first, and Mr. Ward occupied a similar position in the amateurs' class, with huge plants trained on the flat principle, some 4 feet or more in diameter and a sheet of bloom; Mr. Weir, the Elms, Hampstead, was second, and Mr. James, Isleworth, third. Messrs. Dobson were first in the nurserymen's class for six fancy Pelargoniums, and Mr. Weir and Mr. James first and second respectively in the amateurs' class. For half a dozen herbaceous Calceolarias, Mr. James was first and Messrs. Dobson second. Messrs. Dobson showed a good miscellaneous collection of Calceolarias.

**Herbaceous Plants.**—In the class of twenty-four of these in pots, Mr. Ware was first, with a good collection, in which, amongst others, were *Thermopsis Caroliniana*, *Cheiranthus Delavayanus*, *Aquilegia aurea*, *Anthericum Liliastrum*, and *Linum flavum*. Mr. Ware likewise contributed two extensive groups of hardy plants and succulents arranged for effect, for which he was awarded an extra prize. Collections of Pansies, both English and fancy kinds, were likewise furnished by Mr. Ware, conspicuous amongst them being a stand of the very dark velvety kind called Pluto. Messrs. Downie, Laird, and Laing furnished a collection of fancy Pansies, consisting of many fine seedlings and named sorts. Of English Pansies the same firm also sent some fine examples, and also a basketful of their fine new bedding Pansy, Blue King. Mr. Hooper, Bath, likewise exhibited some splendid blooms of fancy and English Pansies. Mr. B. S. Williams showed a basketful of his new bedding *Viola coronata*, named Sensation, of which we have already spoken in favourable terms.

**Miscellaneous Plants.**—Messrs. Veitch exhibited a group of fine small plants, including several varieties of the Japanese Maples; *Tillandsia Zahnii*, with its yellow flower-spikes and dull crimson leaves tipped with green; the handsome *Anthurium crystallinum*; and that prettiest of all Aralias—*A. Veitchii*, with its charming whorls of narrow undulated brown leaves. In this group were also good plants of the Adiantum-like *Paullinia thalictrofolia*, the curiously variegated *Maranta Makoyana*, a superb plant of *Cocos Weddelliana*, with long, graceful, and beautifully arched fronds, and other plants. Messrs. Downie, Laird, & Laing showed a group of plants, among which were the red-veined *Ficus Cooperii*, *F. Chauverii*, different kinds of *Caladiums*, *Pandanuses*, *Ferns*, *Palms*, an excellent plant of *Dieffenbachia Bausei*, variegated *Yuccas*, &c.; and also a group of zonal Pelargoniums, amongst which Mrs. F. Weir, Black Douglas, Marechal MacMahon, Earl Rosslyn, Imperatrice Eugenie, and Princess of Wales were particularly fine. Mr. Ware showed a group of Succulents, and Messrs. J. Verschaffel, Belgium, a basketful of *Pæonies*. From Messrs. Rollison came a large group of plants, including some new kinds of *Crotons*, variegated Pine-apple plants, *Pandanus ornatus* and *Vandermoershii*, *Alocasia zebrina*, and several fine varieties of *Ferns*. Mr. B. S. Williams contributed a large and varied collection of miscellaneous plants, containing, amongst others, *Adiantum Alexandra*, one of the finest leaved of all the Maiden-hair *Ferns*; the prettily variegated *Habrothamnus Hawkshawianus*, several fine examples of *Anacothylus*, *Massevallia Lindenii*, *Cattleya Mendelii*, *Palms*, *Ferns*, *Dracænas*, *Succulents*, *Bouvardias*, and many variegated-leaved plants. Half a dozen of *Clematis* plants on trellises were shown by Mr. Cutbush, and Mr. J. Dinsmore, the Cedars, Harrow-road, exhibited half a dozen fine pyramidal plants of *Mignonette*, for which he was awarded an extra prize. Mr. C. Turner contributed a group of *Azaleas* and some plants of *Primula japonica*.

**Window Boxes, Plant Cases, &c.**—For a plant case for the drawing-room, furnished with suitable plants, Miss Annie Williams was first, with a nice plain Wardian case, in which were effectively arranged *Dracænas*, *Caladiums*, *Coluses*, *Bezonias*, *Ferns*, &c., under which was a carpet of dwarf *Selaginella*. Messrs. Dick Radcliffe & Co. contributed a tastefully planted window jardinet. Miss Williams had the best window-box; it was tastefully filled with *Calceolarias*, *Ivy-leaved* and other *Pelargoniums*, *Cannas*, *Lobelias*, *Petunias*, &c.; at the back was low wire netting, on which *Ivy* and similar plants were trained, and in front *Ivy-leaved Pelargoniums*, *Petunias*, &c., were effectively spread out on a drooping ledge of wire netting, which almost hid the box. Mr. J. Russell was second, and Messrs. Dick Radcliffe & Co. third. For three garden vases for conservatory decoration, effectively planted, Messrs. Rollison were first; in the centre vase was a little plant of *Livistona borbonica*, and the two outside ones each contained small specimens of variegated *Yuccas*. Arranged round these were little plants of *Fuchsias*, *Cytisuses*, *Azaleas*, *Ferns*, and other plants. Miss Williams was second, and Messrs. Dick Radcliffe & Co. were third.

**Table Decorations.**—For sets of three pieces, ornamented with flowers, Miss A. Hassard was first, with tastefully arranged glass stands furnished with *Stephanotis*, *Gardenias*, *Spiræas*, *Schizostylis coccinea*, *Ferns*, blooms of *Cacti*, &c. Mrs. Fenn, Lea Bridge-road, was second, and Mr. Chard third. For two flower-stands for the drawing-room table, Mr. Burley was first, with tastefully furnished stands, in which runners of the Mother of Thousands *Saxifrage* suspended from the top dishes had a charming appearance. Miss E. Blair was second, and Miss Mackenzie was third. Messrs. Adeock and Co., 3 & J, Princes-street, exhibited a collection of artificial flowers.

**Bouquets.**—These were not so good as might have been expected. Wedding bouquets consisted chiefly of choice white and sweet-scented flowers, sparsely relieved with small Fern fronds. That to which the first

prize was awarded was exhibited by Miss Edwards, Balham; it was some 14 inches in diameter; the second came from Mr. Yates, Manchester, and the third from Mr. Chard, Clarendon Park. For three bouquets for balls Mr. Burley was first with well made bouquets of a nice size; Mr. Yates was second, and Miss Williams third.

**Fruit.**—Some good fruit was exhibited, particularly Pines, Grapes, and Strawberries. For the best three Pines of any sort, Mr. D. Wilson, gardener to Earl Fortescue, Castle Hill, Devon, was first with three well-ripened, smooth-leaved Cayennes, and likewise for the best single fruit of a smooth-leaved Cayenne. The best single fruit of any other sort was exhibited by Mr. G. Tillyard, Brocklesby Park, Lincoln, who also exhibited a specimen of Oat's Seedling Pine. The finest two bunches of black Hamburg Grapes were shown by Mr. W. Bones, Havering Park, Romford; they were large, well-set, and ripened, and the berries plump and capitably coloured. Those from Mr. T. Bannerman, Blithfield Hall, Rugeley, Staffordshire, that were second, and likewise those from Mr. Bennett and Mr. Miles, which received equal thirds, were also exceptionally good. For three bunches of any white Grape, Mr. D. Wilson was first with remarkably fine and well-finished bunches of Foster's White Seedling; and Mr. Bones was second with good clusters of Golden Hamburg. For the best single bunch of any white Grape, Mr. T. Miles was first, with a fine bunch of Buckland Sweetwater; and for the best single bunch of any black Grape Mr. T. Bannerman was first, with a fine cluster of Black Hamburg; Mr. Bones was second, and Mr. D. Wilson third with the same sort. Peaches were good, of fair size, and well ripened; the successful competitors for these were Mr. Harris, Mr. Sage, and Mr. W. Gardiner; the last-named exhibitor likewise showed a dish of fine Violet *Hydrangea* Nectarines. For a dish of Figs, Mr. Miles was first with half a dozen fruits of Brown Ischia, and Mr. Wilson second. For two kinds of Strawberries, and twenty-five fruits of each, Mr. T. D. Irving was first, with Sir C. Napier and Lucus. The same exhibitor was likewise first in another class for twenty-five fruits, with very fine samples of Lucus; Mr. J. Lane, of Pyrgo Park, being second, with excellent fruits of President, and likewise first, with the same sort, in the class for six pots of Strawberries in fruit. In the classes for thirty fruits of any black, and the same of any white, sort of Cherry, Mr. Miles was the only exhibitor; but his dishes of both kinds—viz., Elton and Black Circassian—were extremely fine, and well merited the first prizes that were awarded them. Messrs. Munro and Wilkinson, Potter's Bar, showed three samples of their Little Heath Melon, which received a first prize; the second being awarded for samples of May Queen and Tower Hybrid Melons. Two brace of the Marquis of Lorne Cucumber, about 29 inches in length, straight, fresh, and green, were shown by Mr. Bennett, Hatfield House, Herts. Home-grown fruits of the Japanese Loquat were exhibited by J. Blythe, Esq., Woolhampton, Berks; and a good collection of Apples, in an excellent state of preservation, came from Mr. W. Gardiner, Lower Eatington Park, Stratford-on-Avon. In this group, amongst others, we noticed the old Leathercoat Russet, Golden Pippin, Gorse Hill, Easter Pippin, Sturmer Pippin, Hanwell Souring, and Royal Russet.

## COVENT GARDEN MARKET.

MAY 30TH.

HOME-GROWN fruits, such as Melons, Cucumbers, Grapes, Pines, Peaches, Nectarines, Strawberries, &c., are of excellent quality, as are also imported produce. Vegetables are unusually fine this season, and realise good prices.

**Prices of Fruits.**—Apples, per doz., 2s. to 3s.; Apricots, 2s. to 3s. per doz.; Cobs, per lb., 2s. to 2s. 6d.; Cherries, per box, 2s. to 4s.; Gooseberries, per quart, 3d. to 6d.; Grapes, hothouse, per lb., 6s. to 15s.; Lemons, per 100, 6s. to 10s.; Oranges, per 100, 6s. to 12s.; Peaches, per doz., 1s. to 3s.; Pears, kitchen, per doz., 1s. to 3s.; dessert, per doz., 6s. to 18s.; Pine-Apples, per lb., 8s. to 12s.; Strawberries, per oz., 6d. to 1s. 3d.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 3s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 3s. to 6s.; French, 1s. to 12s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, each, 6d. to 9d.; Cabbage, per doz., 1s. 6d. to 2s.; Carrots, per bunch, young, 1s. 6d., old do., 9d.; Cauliflower, spring, per doz., 8s. to 12s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 1s.; Cucumbers, each, 4d. to 1s. 3d.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 2d.; Lettuces, per doz., 1s. to 2s.; Mushrooms, per pottle, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 8s. to 12s.; button, per quart, 1s.; Parsley, per doz. bunches, 6s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 3s. to 5s.; Potatoes, per bushel, 5s. to 10s.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsify, do., 1s. to 1s. 6d.; Savoy, per doz., 2s. to 3s.; Scorzoneria, per bundle, 1s.; Shallots, per lb., 9d.; Spinach, per bushel, 3s. 6d. to 5s.; Turnips, old, per bunch, 6d., young do. 2s.

## ANSWERS TO CORRESPONDENTS.

**NAMES OF PLANTS (Strathallan.)**—*Lonicera Ledebourii*.—(R. T. S.)—Probably *Spiræa Lindleyana* or *ariaefolia*, and Purple Beech—(Frederick.)—1. *Scilla nutans alba*; 2. *Staticia Armeria rosea*; 3. *Clematis montana*; 4. *Corechoris japonicus*; 5. *Bignonia jasminoides*; 6. *Bignonia caprolata*; 7. *Aconitum Napeljus*; 8. *Berberis Darwinii*; 9. *Juniperus sphaerica*.—(Chilham.)—*Aotus gracilima*, a West Australian greenhouse shrub, requiring the same treatment as an *Acacia*, and the Cape *Pelargonium tricolor*.—(A Lover of Ferns.)—1. *Pteris serrulata*, var. *cristata*; 2. *Pteris*, indeterminate; 3. *Adiantum cuneatum*; 4. *Adiantum*, apparently *Capillus Veneris*; 5. *Asplenium laccidum* (sterile frond); 6. *Adiantum affine*; 7. Same as 5, but a fertile frond; 8. *Asplenium Colensoi* (sterile frond); 9. *Pteris cretica*; 10. *Cyrtomium falcatum*; 11. Same as 9, but a fertile frond; 12. *Pteris serrulata*; 13. *Pteris argyrea*.—**PLANT BARROWS (J. R.)**—Trucks with two, three, and four wheels, are better than hand-barrows for conveying plants from one place to another. You will find a useful one for ordinary purposes figured in p. 376, No. 137, of McIntosh's "Book of the Garden."—**PROPAGATION (M. R.)**—*Funkia ovata* may be increased by dividing the roots, the yellow *Alyssum* by means of seeds. Pansies next week.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### FLOWERS FOR THE POOR AND THE SICK.

THERE is at present in many directions a strong movement for giving plants and flowers to the poor in their homes and hospitals. On reading appeals for supplies of flowers I am struck by the omission of demands for winter flowers, it is always for summer; sometimes spring and autumn are included, but one would think that infirmary wards were empty in winter, that disease and death were not so rampant at that season, and flowers were not needful to help to purify the close rooms in the long dark nights. The present is a good time to make provision for winter flowers for the sick, and allow me to explain that in my limited experience among the town poor, anything green is considered a flower, and any flower is a rose. There is no garden so small that it cannot hold a few plants of Thyme and a bush of Rosemary; nor is the stock in any private garden large enough to supply even one district or hospital with these two wholesome aromatic plants. I would include Lavender, but it must be saved in winter for its flowers in autumn. A "beautiful smell" is more prized by the poor than even a beautiful sight. The prejudice against flowers in sleeping rooms is many degrees stronger among the upper classes than among the poor. I pass along to my own room and see the flower-glasses of my friends carefully set outside their doors, or on the window sills for the night, "no sleep and a headache in the morning" being asserted as the certain consequence of sleeping in the vicinity of any and all vegetables. In my own room there are plenty of the flowers in season at the time, and below the window there is a hedge of Sweetbriar, and Honcysuckle, and a border of Stocks, Mignonette, Sweet Peas, Lupins, and common Roses, a bush or two of Lilac, and not far off a fine Sweet Bay; thus I cannot escape the smell of flowers, and yet have lived half a century in ignorance of headaches and sleepless nights.

To resume: Growing a market-garden supply of Thyme and Rosemary for our winter beds, we have been in the practice in spring, when these plants are removed, and after our own supplies for the next winter are taken up and laid by, to distribute what we can spare. We could not supply pots for such a number, nor would the additional weight have been convenient for our benevolent kinswomen who distributed the plants at their "mothers' meetings." We, therefore, selected the most retentive soil there is on our light ground, and kneaded it around each clump. This answered the purpose perfectly, and did not offer the temptation of selling the pot. It occurred to me this winter that we should not wait until spring to give plants, but that a whiff of health and pleasure might be administered, by sending cut Thyme and Rosemary to the Royal Infirmary, made up in little bunches, with one Christmas Rose or two or three Snowdrops in each. Our kinswomen were again only too happy to distribute weekly these flowers through the wards open to visitors. Our many dozens (now amounting to hundreds) went but a little way, alas! but the pleasure they gave cannot be told. From Snowdrops we progressed through Heath (herbacea and carnea præcox), Crocuses, dwarf Daffodils, Grape Hyacinths, Arabis, Polyanthuses, white and red Ribes (one raceme sufficient for each), Stocks that had stood the winter (one head gave colour), Laurustinus, Sweet Briar, Spearmint, and Balm, until the month of May, when everybody can help easily with the host of spring flowers. But, however ample supplies from this garden may become (we sent 400 one day), two points will be all-important—I, that every nosegay, be it no larger than a "bntton-hole," shall have a sprig of a woody, aromatic plant, that does not require to be kept in water to remain alive and sweet, that will neither stain nor litter the bed, that can be crushed under the pillow and sniffed at through the long night, and be still pure and sweet in the morning, and, like Lavender when thrown away into the fire, will, "e'en in its ashes, live its wonted" fragrance—as Rosemary, Sweet Bay, Thyme, Lavender, Southernwood. I name them in perhaps their most useful order.

Point No. 2 is, that all flowers should have been at least an hour in water before being sent away. Unpractised people have a notion that flowers fresh from the garden must be best, and are suspicious of those that they feel have been in water. All who work practically with cut flowers know that this is an utter mistake. Even in cool weather, flowers sent from here (20 minutes) to Edinburgh would arrive limp and short-lived if fresh from the garden, but crisp and firm had they been placed in water for a time. One cannot expect in a hospital that each patient is to be provided with a little mug of water to hold the flowers; there may be one general dish in the ward, where all the little bunches are put. I do not know as to this, therefore I would secure the dry, clean sprig, that entails no trouble to the nurse, nor gives grounds for complaint of wet or mess. I have heard frequently philanthropic people say that we ought to give our best flowers to the sick poor, that there ought to be no grudging where gifts to the poor are concerned; by best, these talkers mean scarce and rare flowers, the actual value of which (not to speak of the cost in growing and keeping them) would have gone far to provide food and fuel for those who, for want of these, have been struck down with sickness and are inmates of the infirmary; and what healthy associations can the poor have with hothouse or rare border flowers? Why should they not be considered, and have the strong-smelling herbs and the flowers they know, and to which some memory may be attached? A memory is a fact, not a sentiment, and sentimental people would thus deprive the poor of their own simple associations. In our ugly and utilitarian Kale yards, there is almost always (and for it only) still room for a bush of Southernwood. I am glad to see it, and again I repeat, Why should the infirmary sick (people often from the country) be deprived of the sprig of "Old Man," with possibly its Sunday memories, because we are accustomed to more "refined" plants and smells?

All sorts of Mints, Costmary, Balm, and pot herbs are prized and preferred. We had lines and plots of these prepared in early spring, to save the Thyme for winter. Sweet Briar we put into the centre of the bunch (or fold a leaf of Sweet Bay sprig round the stalk) to protect the poor sickly hand from the prickles; the topmost spines are too soft to hurt the nose. A long branch of Rosemary, half a yard long, may be cut into lengths, but see that the stalk is cut down close to the topmost pair of shoots in each length, so as to guard against sharp points. Worsted makes the best tying material; short ends and old unravellings that would be wasted, are yet strong enough for these little bunches. They must be firmly tied; yet not too tight, else, if put into water, the stalks cannot benefit, although worsted is a safeguard there.

A handful of earth seems a thing to be had anywhere. Arthur's Seat is ten minutes' distance from the Cowgate, but for all that mould cannot always be got by the poor in garret and cellar. For such contingencies I would suggest a bunch of Spearmint, which will grow and root in water. An additional motive would be, that a top, or two or three leaves, might give a flavour to some little mess that may be sometimes procured. Failing earth and water, I would still urge having a plant, and Houseleeks and Stoncerops, if there is a skylight or window at all, would live on nothing. Here again there might be a combination of use with the pleasure or having the plant. A leaf of Houseleek (*Semp. tectorum*) is a sure allayer of inflammation and "ills" that feet "are heir to." I have sent by post leaves to those who could not afford themselves the relief of a chiropodist, and have been told that they assuaged the pain as nothing else did.

The plants I have named can all bear crushing. A hamper of Rosemary and Thyme, Houseleeks, and Sedums from the country could be tightly packed, and arrive not a bit the worse, even if delayed on the road. I hope these suggestions may be followed up by some of your readers. For ourselves, we intend to make winter our "supreme effort," and hope to be methodical, and use foresight in carrying our plans out. In summer there are always country friends now and again coming in and bringing a nosegay with them for the poor inmates of the infirmary, and bunches come from the market then also occasionally.

F. J. HOPE.

Wardie Lodge, Edinburgh, May, 1873.

## NOTES OF THE WEEK.

— It is not only the Alps of Europe that are brightened with numerous beautiful plants of the Pink and Catchfly tribes. One of the handsomest plants of this kind that we have seen for a long time is a Californian species named Bolander's Catchfly (*Silene Bolanderi*), of which fine specimens were shown at Kensington last Wednesday. It is a dwarf rose-coloured kind, introduced by Mr. William Thompson, of Ipswich.

— THE kingdom of double flowers is rapidly extending, for better or for worse. Our old friend *Lobelia pumila grandiflora* is the last subject. It was to be seen in a double form, last Wednesday, at South Kensington.

— AT the Show at Kensington, on Wednesday last, there were some artificial plants and flowers exhibited, so well done that many did not at first think them to be anything but natural products. They were exhibited by Messrs. Adcock, Princes Street, Cavendish Square.

— IN the nurseries of Messrs. Backhouse and Son, at York, the curious "Spatlum," or "Bitter Root" (*Lewisia rediviva*), is now showing flower freely. A description of this remarkable and handsome plant, with an illustration, will be found at page 701, Vol. I. of THE GARDEN.

— REFERRING to our last week's note on the Chlorococcium, our contributor desires us to correct an error into which he was led by an imperfect knowledge of the locality. The church to which our correspondent refers is St. Stephen's, Hampstead, and not the church at Camden Town.

— TUESDAY next is, we understand, the last day on which tickets for the great show of the Royal Horticultural Society at Bath can be purchased in quantities at the reduced scale. It is reported that an application has been made by one firm in the neighbourhood of Bath, for 3,300 tickets, to be distributed among its *employés*. Let us hope that this example will also be followed by others.

— A MICROSCOPICAL *soirée* will be held at Bath during the show week. The Bath and Bristol Associations have united for the occasion, and a grand collection of microscopes will be the result. The exhibition, which will be held on the Wednesday evening, will be devoted to an illustration of the growth, structure, and products of plants, and to the animal pests that affect the vegetable world.

— WE have this week received from Mr. Jas. Backhouse, of York, specimens of some scarce and beautiful hardy flowers, now in flower in their nurseries, among them being the Pyrenean Adonis, a fine species, with two rows of petals, and a larger flower than *Adonis vernalis*; the long-spurred yellow Columbine (*Aquilegia leptoceras aurea*), with clear yellow flowers, and spurs nearly three inches long; the delicately-coloured *Calochortus cernulea*, the wax-like and rich yellow *Cyclobothra pulchella*—both the last being interesting and pretty Californian bulbs, which Mr. Backhouse finds easy of culture in pots, and Hansmann's Saxifrage, said to be a hybrid between *S. aizoides* and *S. elatior*.

— A TERRIFIC storm passed over the Midlands on Tuesday last. Near Nottingham hail fell in large spherical pieces, causing immense damage to the fruit crop. Gooseberries and Currants were cut clean off the trees, strewn the ground, and other fruits were also very much injured. At Coventry a quantity of glass has been injured in conservatories, and the injury to gardens and to fruit trees there is also considerable. Mr. Lowe, of Highfield House Observatory, states that a considerable number of the hailstones measured two inches in circumference, and that on the cessation of the storm some hundreds were seen that measured three inches in circumference. These stones fell with great force, rebounding two or three feet from the ground, and some trees had a third of their leaves cut off.

— WE are informed that Mr. James Backhouse, of York, has just received from Borneo several new *Trichomanes* of surpassing beauty. One of them is the plant described some years since by Mr. Backhouse in one of our horticultural journals as *T. spernibum*, and another is Mr. Backhouse's *T. setigerum*. *T. Pluma* is also amongst them, and two other allied species, one of which may be *T. capillaceum*.

— IN an address read before the New York Rural Club, Mr. T. P. Quin, an American horticulturist of well deserved reputation, says a good deal in praise of English ornamental gardening. In conclusion, however, he remarked, "that in the more practical part of horticulture we take the lead by at least twenty years. During my stay in England, I visited many of the largest and best-managed vegetable farms in the vicinity of London, and I was surprised to witness their primitive methods, both in their system of cropping and tedious way of doing the work. It is quite within bounds to say, that a man familiar with 'trucking' in New Jersey, will do a third more work in a given time than a man in the same position in an English garden. The ordinary implements used by the latter are clumsy and unnecessarily heavy, and this weight has to be carried around at considerable

waste of strength both of men and animals. For instance, a common digging spade or fork will weigh at least twice as much as one of ours, intended for the same class of work."

— THE Baroness Meyer de Rothschild has made arrangements for sending a supply of cut and other flowers from Mentmore every week for the Hebrew and general wards of the London Hospital.

— MR. SHAW, an English settler in St. Louis, has presented a park to the inhabitants of that town. It is a richly wooded and picturesque domain, situated close to the city, covering 300 acres, and worth £100,000.

— A MARYLAND cultivator says that the Peach growers of the United States are particularly indebted to Mr. Thomas Rivers, for his success in producing the Beatrice Peach, an early variety that is intrinsically good.

— M. FREDERIC HAMILTON has just published at Nice a scientific, historical, literary, and exegetical treatise on the plants mentioned in the Scriptures. Foreign journals are loud in their praises of the research and erudition displayed in this work.

— BARON VON MUELLER reports that great mortality has lately existed among the cattle in certain districts of the colony of Victoria, which is attributable to their having eaten the herbage of a *Lobelia*.

— WE were very much surprised to see at Kensington the other day fresh and fully developed blooms of *Chrysanthemums*, shown by Mr. A. Forsyth, of Stoke Newington. The occurrence of these plants in bloom at this season is quite as surprising as it would be to hear the cuckoo at Christmas.

— THE effect of the flowers and plants in the large tent at South Kensington is very much marred by the numerous rough poles and cross-beams which there meet the eye in every direction. It is rather a pity that a better example in this way is not shown at headquarters. We can hardly expect our provincial shows to be well arranged if such ugly and shanty-like framework is thought good enough for the great London show.

— IN a communication to the Scientific and Medical Society of Innsbruck, Dr. Kerner states, as the result of his observations on Alpine plants, that the growth of the stem and even of the flowers of many species proceeds at the temperature of 32° Fahr.; the flowers may in some cases open, and even mature their pollen, beneath a thick covering of ice, the surface of the glacier being penetrated in innumerable places by their stems.—*Nature*.

— WE have received a coloured illustration of Mr. Wm. Paul's "Waltham Cross" Grape, a magnificent new variety, which has been awarded a first-class certificate by the Royal Horticultural Society. In berry, bunch, and colour it resembles the Muscat of Alexandria, but its flavour is more like that of the Black Hamburg than a Muscat. It is reported to grow and ripen its fruit thoroughly in a house with the Black Hamburg, and it is said the fruit will hang, if required, till February. Mr. Barron, the superintendent at Chiswick, states that "it is certainly the most noble and most handsome late white Grape in cultivation;" and others speak of it in equally high terms.

— THE anniversary meeting of the United Order of Free Gardeners took place the other day at Shrewsbury. The Grand Master, in opening the proceedings, said there were 77 districts in the society, comprising 572 lodges and 37,731 members. During the past year 4,595 members had been initiated, 1,855 had been suspended, and 317 had been expelled. The total income was £39,608 14s. 0½d., and the expenditure £32,580 15s. 7½d., showing a gain on the past year of £7,027 18s. 5d. The number of delegates attending the meeting was 165, at a cost of upwards of £500 to the Order. Mr. J. Figgins, M.P., and Mr. Douglas Straight, M.P., honoured the demonstration with their presence, and dined with the members; and, among others, were the Rev. J. Yardley, Alderman Turner, and Councillor Turner.

— ON Tuesday evening the church of St. Catherine Cree was one of the sights of London, as, indeed, it always is on Whitsun Tuesday, that being the day upon which the anniversary Floral Sermon is preached there for the edification of young children. The congregation, principally children and women, wore either a posy pinned in the breast, or held a nosegay in their hands, as a befitting decoration for a floral sermon. The appearance of the inside of the church was very beautiful. On the pulpit was a bouquet exhibiting great taste in construction, and at which many stolen glances were cast by the fairer portion of the congregation. This triumph of floral grouping was, as the preacher informed us, the present of a young lady, who had presented a similar one to him every year since he first preached a sermon upon flowers. For the happy idea of having an annual Flower Sermon preached at Whitsuntide we are indebted to the Rev. Dr. Whittemore, who preached an eloquent sermon, couched in plain language, and well adapted to the comprehension of his juvenile auditors.

## THE INDOOR GARDEN.

### CYPRIPEDIUM FAIRIEANUM.

THIS is a distinct and charming little plant, and seldom met with in cultivation. It was introduced from Assam some fifteen years ago, and sold at Stevens' rooms shortly afterwards. I believe Mr. Reid, of Burnham, Somerset, was the first to flower this species, although it was named by Dr. Lindley in honour of Mr. Fairie, of Liverpool, who exhibited a plant in bloom before the Horticultural Society, when their meetings were held at Willis's Rooms. Our illustration gives a good idea of its general contour and habit. The leaves are of a pale and rather glaucous green colour, and spread horizontally over the top of the pot or pan in which it is grown. The flowers are borne singly on slender hairy scapes 6 to 9 inches high, and are of a greenish white colour, delicately pencilled with dark green and rich violet purple. The leaves are perfectly smooth, but both scapes and flowers are densely clothed with short hairs, as shown in our figure. There are good specimens of this plant in the collections of John Russel, Esq., of Mayfield, Falkirk, N.B., E. Salt, Esq., of Ferniehurst, and E. G. Wrigley, Esq., of Bury. It is best grown in a cool or intermediate house, and luxuriates in a well-drained compost of turfy loam, peat, and sand, and the top of the pot should be covered with living sphagnum, into which all the Lady's Slippers root vigorously; a shady position and frequent syringings are likewise favourable to it. It generally flowers about September and October, lasting about a fortnight in beauty. A plant of this choice species flowered in the old Orchid house at Kew in 1867, and was an object of much attraction to all who had an opportunity of seeing it. F. W. B.

*Cypripedium Fairieanum* (half the natural size).

### LISIANTHUS RUSSELLIANUS.

As some of your correspondents have lately recorded their experience respecting the growth of this truly beautiful plant, permit me to give you mine. I sowed the seed about the first week in March, in 5-inch pots, half-filled with drainage, the other half, to within about half an inch of the top, being a compost of light sandy loam, peat, and leaf-mould in about equal parts, sifted fine, with a good sprinkling of sand, the top being pressed level and well watered. The seed is then sown thinly, and a little dry sand is sprinkled over it. The pots are then put in a shady part of a Cucumber pit, and

set in saucers filled with water, with a square of glass over them. As soon as the plants are up, and can be well handled, they are potted off singly into 2-inch pots, in the same compost, and again returned to the same situation, until they have got well established and have filled their pots with roots. They are then shifted into 3-inch pots, and kept in the same growing heat. In August they are shifted into 6-inch pots, and kept in the same growing condition until about the beginning of October, by which time they are good strong plants, with pots well filled with roots. In October they are taken out of the pits and placed on the top shelf of a cool

stove, close to the glass, each pot being still placed in a saucer, by which means only the roots are supplied with water—as they are very liable to damp off if kept wet on the surface of the pot. They should remain under the conditions just named until the beginning of February, when they may be potted in 8-inch pots, in a compost of one-half light turfy loam, the rest peat and leaf-mould in about equal proportions, with a good sprinkling of sand, and placed in a pit, the pots being plunged in tan, in a bottom heat of from 80° to 90°, with a top heat of 70° in the day time, allowing it to run up to 85° or 90°. While growing they enjoy a strong moist heat, with a brisk bottom-heat. As soon as they begin to grow they should be stopped at one or two joints, so as to induce them to form bushy well-shaped plants, and about the middle of April they may be shifted into their flowering pots, using the same compost in a rougher state, and again plunging them in the same bottom-heat, frequently stopping them until sufficient shoots are obtained to form a good head. They should then be tied out, and kept in the same moist heat until the flowers begin to expand, when they may be gradually hardened off, to stand in a cool stove

or greenhouse. For my largest specimens I use twelve-inch pots, and after they are placed in the pots in which they are to bloom they are frequently watered with weak guano-water, which appears to suit them admirably. Under this treatment I seldom fail to have fine bushy plants that flower well, and when well grown few plants are handsomer than this *Lisianthus*. M.

### THE FINEST ACACIAS FOR THE CONSERVATORY.

THERE are so many species of these handsome Australian shrubs, that the amateur may well be puzzled in making a selection. It may, therefore, be useful to furnish a list of the very finest kinds, in the

order of their time of flowering. Few plants better repay the care bestowed upon them than these.

	Time of flowering.		Time of flowering.
Acacia cochlearis	... Jan. to March	Acacia Sophera	... April to May
" Riceana	... March to June	" limifolia	... " " "
" viscidula	... March to May	" suaveolens	... " " "
" diffusa	... March to April	" armata	... April to June
" argyrophylla	... " " "	" Drummondii	... " " "
" hispidissima	... April to May	" paradoxa	... " May "
" longifolia	... " " "	" oleaeifolia	... " " "
" grandis	... " " "	" umbulafolia	... " " "
" vestita	... " " "	" Latrobei	... " " "
" taxifolia	... " " "	" floribunda	... " " "
" verticillata	... " " "	" asparagoides	... May to June
" pubescens	... " " "	" pulchella	... " " "

All these plants, which have flowers more or less yellow, are very handsome, and of easy culture in a conservatory or cool house, in heat-soil. In the Mediterranean region, especially at Nice and Hyères, we have seen the greater number of these charming species growing in the open air without shelter of any kind.—*L'Illustration Horticole*.

**Caladium esculentum.**—I found my roots of this nearly rotten this spring. I, therefore, cut out all decayed portions, rubbed the wounds with powdered charcoal, and started the roots in Cocoa-nut fibre and silver sand, in a brisk heat. They started freely into growth, and from each rhizome several shoots were produced. I cut off these after they had grown a few inches, with a small piece of the old root attached to them, and some young roots, and potted them separately, in light soil, replacing the old roots or rhizomes again in the bed, after rubbing over their wounds with powdered charcoal. The younger shoots that were too weak at the first examination to be separated soon got strong, and in their turn were similarly separated and potted, and thus I continued until the root-stocks were completely exhausted, and had yielded every shoot capable of being made into a separate plant. Thus, although my prospects of obtaining a stock of *Caladium esculentum* in March were poor, I have now (May 26) an excellent and numerous progeny of healthy plants; I never had, indeed, such an abundance of them. In former years I only used whole roots, starting them into growth about the 1st of March, and rubbing off all growths except two or three, and in this way I maintained a good stock of strong plants; but under exceptional circumstances the mode of raising young plants just described may be found worth a trial.—**JAMES MACDONALD.**

THE GARDEN GUIDE.

SUFFOLK.  
BARTON HALL.

This place is distinguished for its arboretum, which contains some fine specimens of Catalpas, Magnolias, and other trees, as well as of Conifers. Of the latter, the following are the measurements of a few of the finest specimens:—

	Height, feet.	Circumference of trunk 4 feet from the ground, feet.
Abies Douglasii	... 54	... 7
" canadensis (Hemlock Spruce)	... 20	... 2½
" Menziesii	... 40	... 1
" Klappow	... 35	... 1
Picea cephalonica	... 51	... 8
" Praseri	... 38	... 3
" Bunsapo (common Silver Fir)	... 105	... 9½
Prun. excelsa	... 34	... 1½
" monticola	... 35	... 1½
Carpinus sempervirens	... 30	... 3
Cryptomeria japonica	... 30	... 3½
Taxodium sempervirens	... 32	... 4
Wellingtonia gigantea	... 23	... 2½

The Douglas Fir and the Picea cephalonica are doubtless the finest trees of their kind in East Anglia. An Indian Horse Chestnut, some 30 feet in height, has flowered freely at Barton for years, and seems as much at home as the common white or scarlet Horse Chestnut. Around the house are nice flower gardens and shrubberies, and a pretty conservatory. The kitchen garden is close to the house, but planted out. It contains convenient ranges of forcing houses, Vineries, plant houses, Ferneries, &c., and in front of the main range of glass a pretty flower garden, sheltered, and mainly devoted to Roses and herbaceous and bedded-out plants. The garden is of good size and quality, much, however, overhung with forest trees along its upper boundary wall. Here is a novelty, in the shape of a prettily variegated Apricot tree, which fruits and grows as freely as

other sorts. Its leaves are more or less splashed with silver. The Palmise system of heating was practised here successfully for many years, and the Grapes grown under it were remarkably good in quality. The pleasure grounds and gardens at Barton may be said to combine both the ancient and modern styles, as well as the usual characteristics of the villa and the country mansion.—Proprietor, Sir Charles Bunbury, Bart.; gardener, Mr. W. Allan. Distance from Bury St. Edmunds, 3 miles.

FORNHAM PARK.

The park here is extensive and well wooded. The gardens and grounds, too, are large and interesting. A small geometrical garden is placed in front of the house, bounded by a broad terrace of gravel and a retaining wall that overlooks the park and lake. The latter has been greatly improved by planting on the farther side of it Rhododendrons and other shrubs, Pampas Grass, &c. The lawn, which is skirted with thriving shrubberies, is furnished with some venerable Cedars, young Conifers, and other trees. The kitchen gardens are large, and Grapes, Peaches, Melons, Cucumbers, and the usual kinds of plants for furnishing and cutting are well and plentifully grown. On the back of the conservatory the *Luculia gratissima* flowers beautifully, and the only regret is that so sweet a plant should bear cutting so badly; hardly are the flowers fairly severed from the tree than they begin to fade. The range of glass reaches right across the kitchen garden, and against one of the walls is an excellent Peach case.—Proprietor, G. Gilstrapp, Esq.; gardener and forester, Mr. Dring. Distance from Bury St. Edmunds, 2½ miles.

HENGRAVE HALL.

This is a fine ecclesiastical-looking mansion in the Tudor style, enclosing a quadrangular embattled court. It is over three hundred years old, and has undergone considerable alterations and improvements. Surrounding it is a fine park, well wooded, but lying rather low. It covers about 300 acres, and contains a lake near the entrance. The gardens, which join the house, were remodelled a few years ago, and laid out in the terrace style with steps and vases. They are well planted and furnished, but the site is not favourable for the style, the position of the house and its surroundings being flat. The kitchen garden is surrounded by good walls, well furnished with fruit trees. Peaches, Pears, and Cherries do remarkably well at Hengrave, where there is a nice range of plant houses.—Proprietress, Lady Gage. Distance four miles west of Bury St. Edmunds.

NOWTON COURT.

This pretty modern mansion in the Tudor style is surrounded by extensive pleasure grounds and gardens. Of late years most of the choicer Coniferae have been planted in sheltered positions in the shrubberies, park, and belts of plantations, and numbers of them are making rapid progress. The system of sheltering by commoner plants, and gradually cutting them away as the more tender trees grow, is very favourable to the growth of the choicer trees. Tree Paonies, herbaceous ones, and many other hardy perennial plants and shrubs, are remarkably well grown at Nowton. A neat conservatory is attached to the mansion, and there are several groups of flower beds and gardens tastefully furnished. The shrubberies are extensive, and there is a lake of considerable size, and dense masses of trees and shrubs to shut out the grounds from the public road. The kitchen garden contains some good Vineries. Quantities of seedling forest trees, young shrubs, and trees from cuttings, are also raised and nurtured here until fit for planting out in their permanent positions. Within a few years Nowton promises to be one of the best furnished places in the county as regards rare and choice trees and shrubs. Roses do remarkably well here, and there is a fine collection, many of them being purchased direct from the Parisian and other continental nurserymen.—Proprietor, Henry James Oakes, Esq.; gardener, Mr. Jolly. Distance from Bury St. Edmunds, two miles south-east.

RUSHBROOKE HALL.

This fine Elizabethan mansion, which is surrounded by a moat, occupies a commanding site in a beautifully undulated and richly wooded park. The house forms three sides of a square, and contains a fine hall, which was a place of royal resort in the days of Elizabeth. The gardens partake of the same ancient character as that of the hall, and bear traces of much grandeur and beauty, in sundry sunk walks, old shrubberies, and Roseries. The kitchen gardens are near the house, and are celebrated for their vegetable and fruit growing qualities. The position of Rushbrooke Hall is one of the finest in the country, and, what with the River Lark washing, as it were, the very feet of the building, and a considerable lake, it has all the elements of landscape beauty ready to be worked up into a handsome picture by the eye of genius and the hand of taste.—Proprietor, the minor son of the late Col. Rushbrooke; gardener, Mr. Westley. Distance three miles south-east of Bury St. Edmunds.

## THE FLOWER GARDEN.

### STOCKS.

This is emphatically the season for Stocks, for during May we get the grand Bromptons, the wonderfully floriferous Queens, the beautiful dwarf Intermediate, and in some cases good Ten-week and pyramidal kinds that have been treated as Intermediates through the winter. For weeks past I have had some dozen kinds or so in flower, and most delicious they are, filling the air with sweet perfume, and adorning the garden with beautiful flowers. The grandest of all Stocks are the Giant Bromptons, tall magnificent plants that carry huge spikes of flowers some 9 inches in length, and as massive as they are long. Why do not gardeners employ these fine plants more freely than they do? The Brompton Stock might be planted out for the summer time in any out of the way spot, and then early in the year be lifted with good balls and planted about in kitchen garden borders, or, indeed, in any place where, when in flower, they can show themselves off to advantage. No better place for them, however, can be found than dwarf shrub borders, to which they should be transplanted at once from the seed bed. The Bromptons comprise scarlet, white, and purple colours, but the latter is of an inferior quality; indeed, it is not the true giant variety. A good "strain" of the white kind is rare. I, however, got some seed of it out of a cottage garden in Hampshire, saved from plants that grew over three feet in height, and which produced plenty of double flowered plants. Seed of the Bromptons should be sown in the open ground about the middle of April, and then strong stout plants can be got before winter sets in. For general cutting, no other Stock beats the Queen, as it produces branches all over it by dozens, every bit of which can be used. Seed of this must also be sown in April, and treated as that of the Bromptons; the Queens are, however, the hardiest of all Stocks, and stand the winter well. In their case the purple is the commonest colour, then red, and lastly white. These Stocks are great rarities in large places; indeed, they are seldom to be found except in cottage gardens, and then only in isolated cases, and usually one sort in a place. I have seen the white Queen, but not recently. I should think that if these Stocks were grown in considerable quantities in some of our market gardens, and under overhanging fruit trees, they would furnish a supply of valuable flowers for market purposes. The Queens, if of a good "strain," furnish 60 per cent. double; the quantity of flowers, therefore, that a thousand or two of plants would yield would be enormous. These Stocks, when well managed, grow about 15 inches in height, and as much through. The best of all the Intermediates is the true East Lothian "strain," being in habit very dwarf, robust, and branching, but the plants belonging to it are not quite so early as some of the continental kinds. Seed of it should be sown early in August, and when large enough the plants should either be potted up singly into 60-sized pots, or else be pricked out into a cold frame, there to stand the winter. In this section may be found purples, whites, and scarlets, all very clear and decided. The proportion of doubles which they produce is wonderful, at least 80 per cent., and where such is the case it is apparent that the seed of fine double "strains" must always

be scarce and dear. There are some exceedingly fine forms of the Ten-week Stock, known as the Giant, that also produce the three colours usually found among Stocks in great purity and excellence. These I have now in fine condition, but they are best sown early in the spring and planted out for summer blooming. They are branching in habit, flower for a long period, and are useful for supplying cut flowers in the autumn. The Queen among pyramidal Stocks is *Maive Beauty*, which forms a most massive spike of a delicate mauve tint, and emits a delicious perfume. Seed of this sown in August, and the plants treated as Intermediates, will, if potted up singly into 32-sized pots, yield some valuable plants for the decoration of either the sitting-room or conservatory. It is a Wallflower-leaved kind, and produces about 75 per cent. double. There is also a lovely new pyramidal Stock named *Violette*, that produces flowers of a delicate violet blue colour. This is likewise a good pot variety for spring use, and is a grand summer Stock. It produces about 80 per cent. of double flowers.

Few plants are greater favourites with the million than Stocks, and few trials of flowers, such as are common at Chiswick, would be more interesting than one of a complete collection of them, showing, as it would do, what strains were reliable and what were not.

A. D.

### FLORAL WALL COPINGS.

I NOTED in the neighbourhood of Twickenham, the other day, that the top of a high brick wall was furnished with strong robust plants of the garden *Antirrhinum*, firmly rooted in the mortar. That these, when in flower, must have a pleasing appearance there can be no doubt, and one is tempted to ask, Why are not the tops of walls generally more utilised in that way, especially as a long length of flat wall top, especially if looked down upon, is the very reverse of ornamental? That *Antirrhinums* thrive so well on walls indicates their special adaptability for such positions, and Wallflowers are also equally hardy and capable of existing on the most meagre root-hold. Of course the mere scattering of seed on the top of a wall, or the thrusting it into the interstices of the bricks, may have but a partially successful result, but if a mixture of cow-dung and fine loam, in about equal parts, was plastered some two inches thick in the centre and bevelled off at the sides, all along the top of the wall, and some seeds of suitable plants were shaken over it whilst wet, there can be little doubt that a floral coping of uniform character would soon be produced. Perhaps even better than seed sowing

would be pricking in at intervals small plants of Wallflowers, *Antirrhinums*, and such other hardy plants as would probably thrive in such a position. The whole of the remaining surface of the mixture might then have pricked into it bits of creeping *Sedums*, or *Antennarias*, or any of those creeping hardy alpines of which we have now such an abundance. Walls, especially if high, take many years before they can be covered with Ivies or other climbers, and even then could in no case produce so pleasing an effect as could be got from such a coping as I have indicated. Plants that easily reproduce themselves from seeds would always maintain a succession. There are often many spots about a place that are not visible on the ground level, but which, when looked down upon from an upper window, are the reverse of pleasing. Such spots as these may easily be decorated in the way indicated, and where so done well, the result, I am sure, will amply repay the labour.

A. D. B.

**British Orehids.**—How can I best cultivate these, especially the varieties of *Ophrys*?—J. E. C., *Q. J. J.* [When dormant, let them be lifted carefully and potted in soil somewhat resembling that in which they naturally grow; the pots should then be plunged in

Flower of *C. Fairianum* (natural size). (See p. 431.)

ashes in a cold frame partially shaded, and they should not be watered until they start into growth, and even then very carefully. As a rule, they like a soil somewhat chalky in character. If that cannot be obtained, use light turfy loam in which some broken limestone or chalk has been mixed. Do not hasten their growth too much; water them moderately, but regularly; and always keep them in a cool and airy place, such as a frame or greenhouse. Just as they are about to start in spring, they may be repotted in fresh soil, but in the same sized pots, taking care not to injure the roots in the operation. The plan of growing them in beds out of doors sometimes proves unsatisfactory; but they often succeed in a shady border raised a few inches above the general level, so as to throw off superfluous moisture in winter. They dislike heavy or cold rains; and, therefore, a covering of oiled canvas, or other waterproof material, not only in winter, but in summer, and a thin mulching of short manure over the beds, will be found to be of advantage to them.—F.]

### SINGULAR CUCKOO FLOWER.

WITH the Meadow Bittercress or Cuckoo flower most people are acquainted, seeing that it grows abundantly in moist meadows throughout England, Scotland, and Ireland. In a bog in the south-west of the latter country I picked up, the other day, an interesting monstrosity of the double-flowered

Meadow Bittercress.

variety of this really pretty native plant, of which I forward you a sketch. The singularity consists in each of the flowers producing a second and smaller flower from its centre, this going on to produce a third in like manner. This abnormal elongation of the floral axis, which occasionally occurs in Roses and one or two other plants, gives this handsome little plant a very remarkable appearance. H. NOEL HUMPHREYS.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Lilies.**—The following are now in bloom at Heatherbank, Weybridge:—*Szewitsianum*, *tenifolium*, *Thunbergianum*, *carminatum*, *pyrenaicum*. Almost open, *Thunbergianum bicolor*, *parvum*.—W.

**Camassia esculenta.**—A patch of this is in fine bloom just now at Heatherbank; it grows on rock-work and is very beautiful, associated as it is with *Omphalogramma*, *Scilla campanulata pallida*, and other plants of that kind.—B.

**Hellebores from Seed.**—When it is desired to increase any of these plants from seed, the best way is not to disturb the ground around the plants, when they will be found to sow themselves. In this way most of the kinds increase freely in Mr. Ellcombe's garden at Bittou.—R.

**Tulipa Gesneriana.**—This is grown extensively in the Royal Botanic Gardens, Regent's Park, and is perhaps the most showy of all Tulips. Its colour is bright crimson scarlet, with dark blue centre. It is later and a little taller than the ordinary single varieties. A bed of this Tulip is both striking and effective, and when once seen not readily forgotten. I would recommend those who have never grown it to procure some bulbs next October or November.—O.

**Pansies in Pots.**—What is the best method of growing Pansies in pots, so as to bring them into flower in February? Where should the plants be placed, and what degree of temperature should they be grown in?—M. R. [It is scarcely possible to get Pansies into bloom in February. It might be done by having strong plants, showing flower in October, carefully lifted and potted from the open ground, kept close in a cold frame till they were established, and then removed to a shelf in a greenhouse near the glass. They will neither stand much heat nor a close atmosphere; should mildew make its appearance, apply at once covers of sulphur.—J. L.]

**Rose Stocks.**—Would you kindly name a few Roses that do well on Briars, and also a few that succeed best on the Manetti stock?—E. P. R.—[All Roses do well on the Briar, but some few do not succeed on the Manetti stock when planted in the open ground, as for instance:—*Tea Gloire de Dijon* and its relations, *Belle Lyonnaise* and *Madame Harand*; Hybrid Perpetual—*Marquis de Morny*, *Reine du Midi*, and some of the *Comte de Nanteuil* race, *Henri Lechaux*, and *Madame Crocyon*; but with these exceptions, most of the Hybrid Perpetuals bud freely upon, and grow finely on the Manetti.—The dwarfier Teas, which do well on it in pots, do not always thrive when grafted and planted out of doors on this stock; it is too vigorous.]

## THE ARBORETUM.

### BERBERIS ASIATICA AS A HEDGE PLANT.

THIS flowers and ripens seeds freely with me here in Devonshire, and I sow the seeds annually in drills, or broadcast in beds, in the open ground, about the first week in March, in a light soil, letting them remain undisturbed until the spring after. I then plant them out in the nursery in rows, about 15 inches row from row, and about 6 inches plant from plant. In two years they make fine strong bushes for permanent situations. Finding the plants to be free growers, nearly evergreen, and very strong, and raising, as I do, many thousands of them every year, I began to plant them out for hedges, and they succeeded particularly well both on banks and on the bare surface. The latter I can highly recommend for dividing allotments in cottage gardens, and, as this Berberry is free from mildew, it can be kept clipped with shears or shorn with a reaping hook to any width required. When planted on a bank it makes a beautiful hedge, by cutting out the very luxuriant shoots about twice a year to within an inch or two from whence they grow, allowing the side and weak growth to form the hedge. I have a hedge so treated, which has been planted upwards of twelve years, and at this time it is not more than 4 feet high and about the same width; and with the same treatment it can be kept to the same size. In planting this Berberry for hedges, keep the plants a foot apart, and, if the hedges are to be kept shorn, in single row; but if to be kept in more natural style of growth, plant two rows, not more than 1 foot apart, and the plants the same distance asunder, but put them in alternately. When strong this Berberry is proof against attacks from cattle.—C.

**Trees and Shrubs for Suburban Gardens.**—The illustrations and remarks which you have given from time to time upon the subject of what suburban gardens might be, have led me to the determination of rearranging and replanting my garden, with a view to produce, as far as circumstances will permit, something like the effect referred to in your illustrations. My garden is stiff clay, situated in a northern suburb, on a hill, and exposed to the north and north-east. Under these circumstances, I should like to have your opinion as to the most suitable trees and shrubs for planting for effect, hardy, quick growing, and handsome.—R. T. S. [The following trees and shrubs will suit your purpose, viz.: *Crataegus Aronia*, *Layi*, odoratissima, incisa, punctata, *Douglasia*, cordata, *prunifolia*, *coccinea*, *nigra*; *Acer Lobelii*, *macrophyllum*, *eriocarpum*, *Neapolitanum*, *striatum*, *Pseudo-Platanus Leopoldii* and *purpureum*, *platanoides dissectum*; *Aesculus rubicunda*; *Ailantus glandulosa*; double red and white Peaches; *Cotoneaster frigidula* and *Simonsii*; *Cercis Siliquastrum*; *Halesia tetraptera*; *Philadelphus speciosus*, *Gordonianus*, *grandiflorus*; *Pyrus intermedia*, *pinnatifida*, *spectabilis*; *Robinia hispida*, *macrophylla*; *Rubus odoratus*, *spectabilis*; *Spiraea Lindleyana*, *ariaefolia*, *Nobleana*, *bella*, *callosa*; *Syringa Emodi*; *Tilia alba*; *Weigela rosea*; *Forsythia viridissima*; *Berberis Darwinii*; *Calycanthus florida*; *Daphne Laureola*; *Garrya elliptica*; *Dentzia crenata* (double); *Cytisus elongatus*; *Halimodendron argenteum*; *Hypericum prolificum*; *Leycesteria formosa*; *Ligustrum japonicum*; *Ribes aureum*, *speciosum*; *Magnolia conspicua*, *gracilis*; *Ilex latifolia*; *Viburnum plicatum*; *Alnus cordata*.—G. GORDON.]

**The Weeping Elm.**—Among the ornamental trees of a lawn none have a finer effect than the Weeping Elm (*Ulmus montana pendula*). It is most suitable, from its peculiar habit of growth, for planting singly, as isolation best accords with its character. The branches in old trees are found turned abruptly from the main stem, and strike out in a direction between horizontal and perpendicular. They assume a broad, spreading, fan-like form, bearing a great profusion of large, dark green leaves, which form a complete shade to the ground below. As it is of rapid growth where the soil is good, and very ornamental, it should be on every lawn. It is also one of those trees which will bear transplanting readily, and when established it will produce shoots in one season from twenty to thirty inches long.—P. F. K.

### NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Weeping Trees for Lawns.**—Will you kindly tell me what weeping trees are the best for a lawn, as I have only got a Weeping Willow?—J. B. M. C. [The Weeping Wych Elm, Weeping Beech, Weeping Birch, Weeping Ash, Weeping Sophora, Weeping Larch. The Kilmarnock Weeping Willow, Dutch Medlar, Weeping Hawthorn, Weeping Aspen, and Weeping Mountain Ash.]

**Evergreen Trees for a Churchyard.**—I will feel grateful if you will tell me the names of some ornamental trees or Conifers, to line an avenue in my churchyard?—J. B. M. C. [The Hemlock Spruce, the Irish Yew, the Lawson Cypress, Thuja Lobbi, *Cryptomeria elegans*, *Cupressus sempervirens*, *C. Nuttallensis*, *C. Goveniana*, Irish Juniper, *Juniperus rigida*, and *Abies Smithiana*.

# THE FRUIT GARDEN.

## POT VINES FOR EARLY CROPS.

EVERY day's experience convinces me of the utility of growing Vines in pots for early Grapes, and it is a matter of surprise to me that, in establishments where these are grown, the pot Vine system has not hitherto been far more generally adopted. Permanent Vines will survive the strain of early forcing for a year or two, if cropped moderately and carefully tended, but the crops get lighter and lighter year after year, till in the end they hardly repay the labour of producing them, not to speak of the fuel. In these days, when coals are so dear, people are apt to look at the matter in this light, and are naturally anxious to utilise means and materials to the utmost. In the matter of early Grapes, therefore, I do not hesitate to say that the pot Vine system is the only really remunerative one, if carried out intelligently. I am simply urging a perfectly easy and economical practice. I estimate from reliable data that in a given space pot Vines will produce three or four times more fruit than permanent ones will in a constant way during the months of March, April, and May. I have at the present time thirty pot Vines swelling their fruit, which are twelve months old about this date (April 12), from eyes. They occupy just half the space permanent plants usually require, and they carry in the aggregate 180 bunches of fruit, such as permanent Vines never show after a few years' forcing. I ought to say that the number of bunches just named is what they are allowed to carry, for they showed more; but they will, if all is well, be forced for a still earlier crop next year, before being discarded, and so are cropped moderately, if six good bunches from a plant 7 feet high or so can be called a moderate crop.

### HOUSES FOR POT VINES.

When Vines in pots are forced annually for the earliest crops, proper accommodation for them should be provided, and something like a system pursued. Two houses will be required—one for growing the Vines in from eyes the first season, and another for fruiting them in the next year. As earliness is a chief consideration, lean-to houses with a southern exposure will be found to answer best. The accompanying section (fig. 1)

Fig. 1. Section of Growing House for Pot Vines.

represents a useful form of house for the first year's growth and one which can be turned to good account for various other purposes, such as Cucumber, Strawberry, or French Bean forcing, &c., when not occupied by the Vines.

It will be seen by the section just given that there is accommodation for two rows of plants, and that the pots are not plunged, but rest upon the ground and shelf, and that both rows have plenty of light. In calculating the length of house required, 14 inches at least of space must be allowed for each pot. Thus a house 30 feet long would hold fifty plants. The fruiting house may be of exactly the same form, allowing 2 feet instead of 14 inches space for each plant, but a loftier

house is to be preferred for fruiting purposes. In the first season the Vines make their growth during the most favourable portion of the year, when but little fire-heat is needed, and when ample ventilation can be given to even the smallest structures; but as forcing is carried on in the second, or fruiting year, during the dull months of winter, low narrow houses are apt to become close and muggy—a condition not at all favourable to Vine culture—as they do not permit of the temperature and ventilation being maintained so steadily as do wide and high houses; and as the latter will contain a proportionately greater number of plants, they are not more expensive. Fig. 2 represents a good form of fruiting house,

Fig. 2. Section of Fruiting House for Pot Vines.

and shows how the Vines are arranged so as to accommodate the greatest number without obstructing the light.

In the above arrangement, the shortest plants are placed in front, and upon the shelf on the back wall, the tallest plants being reserved for the middle row, in order that their tops may be near to the glass. Arranged in this way, we secure, in the aggregate, a length of bearing wood considerably greater than the available length of rafter; while most of the plants stand upon the floor, which is an advantage, as they can be easily attended to, and the pots can be packed around with leaves, to prevent evaporation from their sides, thus saving watering, and securing an even root-temperature than would be the case if the pots were exposed. Why, it may be asked, not have both succession and fruiting houses of the same form? Because, in fig. 1, the plants can be kept near the glass from the beginning—a matter of considerable importance in propagating Vines from eyes, and were we restricted, through circumstances, to one of the two forms just given, fig. 1 would be chosen for this reason alone; so much depends upon the first year's treatment.

### GROWING AND FRUITING THE VINES.

Every healthy Vine-eye, under fair treatment, should make a vigorous cane the same year. Firm, short-jointed wood, with plump buds, should be selected from healthy Vines which have ripened their fruit about Midsummer or early in autumn, as these generally produce the best ripened wood. The cuttings may be taken when the Vines are pruned, inserted in soil, and kept moderately moist till the time arrives for preparing the eyes. Two systems of propagation are followed, about the relative advantages of which it may be proper to speak. The plan most generally adopted is to insert the eyes in 4 or 5-inch pots, filled with fine soil; the other is to insert them in square pieces of turf, first scooping out a hole large enough to hold a Walnut, in the centre of each turf, to receive the eye, which is afterwards covered over with fine soil. The pot system is a good one if carried out intelligently; but that is not always done. Its disadvantages are, that if the plants are not well attended to, they are liable to receive a check, thereby arresting their growth prematurely; their roots are also apt to be

injured in shifting from one pot to another, and a check sustained at this stage is never entirely recovered. By the turf system, all these evils are avoided, for, if even the most ordinary precautions are taken from the time the eye is inserted in the sod till it has completed its growth in autumn, it receives no check. For pot Vines, the eyes should be put in by the first week of February, in order that they may complete their growth as early as possible. If pots are used, prepare as many 5-inch ones as there are eyes to be planted. Put an inch of clean crocks in the bottom of each, and fill them with a mixture of sifted soil, consisting of equal parts of loam, leaf-mould, and silver or river sand. Press the soil moderately firm, and the pots are ready for receiving the eyes. Prepare these by cutting them out with a sharp knife—or, what is better, a sécateur—leaving about half an inch on each side of the bud; then take a slice off behind the bud, about half-way into the pith, and they are finished. Put one eye into each pot, pressing it down just deep enough to bury the bud half an inch, and then plunge the pots where they can have a bottom heat of 75°. If sods are employed, prepare as many turves as are wanted, each 7 inches square, 2 inches thick, of a fibry texture, and free from wire-worms. Scoop out a hole in the centre of each turf large enough to bury the eye, and arrange them closely together in a stove, vinery, or pit, where they can have the same amount of bottom heat as has just been recommended for eyes set in pots; then plant an eye in each turf, cover them with fine soil, and fill up, also, the crevices between the sods or turves. The eyes will soon break; and, as soon as those in pots show a decided disposition to grow, which they will indicate by throwing out one or two strong tendrils, transfer them to 14-inch fruiting pots, taking every care to preserve the roots from injury. Those in sods may be potted—or, rather, lifted into the fruiting pots previously filled, to within 4 inches of the top, with soil—as soon as their quill-like roots appear at the sides of the turves. The pots should afterwards be filled up level with the tops of the sods. The after treatment during the summer consists in watering—at first cautiously, till the plants are well rooted in their pots; but after that copiously, never allowing the soil to get dry. The pots should not be plunged, but set on slates, to prevent the roots from getting through into the bed. Time being an object, the plants should be exposed to a good light, and subjected to a temperature of 90° or 95° in sunny weather, air being always admitted. A high temperature generally, with a free circulation of air and abundance of water at the root—not forgetting regular supplies of liquid manure—must be maintained. With such treatment the Vines will rush up speedily, and should be topped at the height of 7 feet. After the first pinching, every shoot or lateral should be pinched to a joint as soon as they can be got hold of. This practice accelerates the ripening of the canes, and throws increased strength into the main leaves, which get broad and thick, with great plump fruit-buds at their axils. By the middle of July the canes will be getting pretty ripe and brown, and from that date the temperature may be gradually reduced and abundance of air admitted at all times, until the beginning or middle of August, when the ventilators may be thrown permanently open day and night, fire-heat discontinued, and the plants left to harden off gradually. By the end of September, at the very latest, they must be pruned, by cutting off all the laterals and leaves along the canes close to the eyes, and the plants should be at the same time removed from the house to the coolest quarters available, say a Peach house where the fruit has been gathered. Here they may remain till the middle of November, when they must be transferred to the fruiting house. As they are not to be retained longer than one or two years at the furthest, we can afford to push them faster than permanent Vines; therefore they may be started at a temperature of 50° or 55° by night, and from 60° to 80° by day, according to the weather. At first the canes are better laid horizontally till they break, when they may be tied to the wires. As a rule, each Vine will show from eight to twelve bunches; if they are to be fruited the following year, the number may be reduced to six of the best; but if they are only to be retained one year, seven or eight bunches may be left on each plant. After this, the only attention required will consist in tying the shoots, stopping laterals, thinning the berries out freely, and watering liberally till the fruit is cut. From the time the

fruit is set till it begins to colour, weak liquid manure must often be given. The best soil for pot Vines is three parts of good strong loam, one of rotten hotbed manure, and one of sand. The pots should also be surfaced with rich soil before they are started in November. J. S.

### THE FRUIT CROPS IN SOMERSET.

We had a glorious rainfall a few days ago, and the fruit and Potatoes are generally safe, except in the case of low lying ground or near water. On the night of the 19th and morning of the 20th ult., the thermometer went down to 5° below freezing, but no visible damage has occurred, and with a nice soft S.W. wind and gentle rain I hope our fears for the crops are over as far as frost is concerned. We have now, I think, only birds and heavy gales to fear. Pears are in many cases half an inch in diameter, Apples are well set, Gooseberries and Currants look promising. Plums are thinly sprinkled on some trees. The orchards about here are sheets of bloom, and the leaves well expanded; in fact the size and health of the foliage are this season remarkable, especially in the case of Pears on the Quince; the very wet season of 1872 evidently suited these surface rooting trees, and thus it may be inferred that we ought either to plant them in naturally moist ground, or mulch them with short litter, and give them a good watering now and then. Let me, however, caution parties as to how they apply water. It should not be given unless the trees are either mulched or the ground is forked over soon after watering, otherwise the soil will crack, and evaporation will take place to a detrimental extent. Strawberries are coming into full bloom, and the gentle showers we are now having will, I think, ensure a crop. I never find my crops good unless it rains well when the plants are in flower. Keen's Seedling, which is now a sheet of flower, may be said, as regards excellence, to be the Strawberry grower's mainstay. It has stood his friend for over fifty years (it was raised in 1820), and it still keeps the field as the most reliable sort. Next to it in worth is President, a kind which throws a strong bold truss of bloom, well up above the leaves; its fruit escapes being washed into the earth, and withal it has but few rivals as to flavour, size, and bearing qualities. Hericott de Thury is an admirable sort for preserving, a strong and free grower, a great bearer, and the fruit is scarlet to the core.

Merriott.

J. SCOTT.

### HUCKLEBERRIES.

(GAYLUSSACIA.)

The Huckleberry (more properly Whortleberry) belongs to the Vaccinium family. In England it is called the Bilberry, in Scotland the Blaeberry. There is a white Whortleberry found in Britain, and occasionally in North America, but it is rare. The European Whortleberry (*Vaccinium Myrtillus*) is dark purple, and grows on bushes varying from a few inches to 2 feet in height, with ovate deciduous leaves, although some species are evergreen. The Bog Whortleberry (*Gaylussacia frondosa*) is common in Northern Europe and in Asia, and extends even to the ice-bound shores of Greenland, where it covers large areas of marshy land. The bushes of this berry, in many instances, grow to be more like trees than shrubs, in this country, at least, sometimes attaining a height of 8 feet. The fruit is much larger than the common berry, but inferior to it in flavour. There is a species of Whortleberry nearly akin to the Cranberry, and which was formerly classed with that family. It is found in this country, and in the north of Europe and Asia. It is red, and possesses all the acidity of the Cranberry. The plant is a very pretty dwarf shrub, and is evergreen. Large quantities of the red Whortleberry are sold for Crauberrys in the south of Europe, in Aberdeen, Scotland, and other places. It is used in the same manner and for the same purposes. There are many more varieties of the Whortleberry, the most of them natives of this country. The most common, and the ones which get into market, are the early "sugar-bines," the purple "low-bush" and the jet-black "high-bush." This latter is the latest of all, and after it has ceased to be sought for by anxious "pickers," forms food for weeks for millions of wild pigeons on the barrens where it is found. As New York consumes thousands of bushels of Huckleberries, it may be of interest to the consumers to know where they come from. The great Huckleberry patches of America are in the southern part of this State, North-eastern Pennsylvania, and Northern New Jersey. The counties of Sullivan, Orange, and Ulster in this State, and Pike and Monroe Counties, Penn., supply New York city's demand for the fruit, and Carbon and Lehigh Counties, Penn., furnish the Philadelphia markets.—*New York Tribune*. [*Gaylussacia Pseudo-Vaccinium*, a neat shrub with handsome red flowers, was formerly grown in our greenhouses.]

FILBERTS AT ASHRIDGE PARK.

At few places are these better managed than at Ashridge Park, where they are grown, as will be seen by the accompanying illustration, in the form of pyramids. They are kept to a single stem for about one foot from the ground, and are afterwards pruned as one would a pyramid red or white Currant tree, *i.e.*, the side shoots are spurred in close, leaving eight or ten eyes on the leading shoot. As they generally grow strongly when about 4 or 5 feet high, they are lifted

Pyramidal Filbert tree, Ashridge Park gardens.

or root pruned, which induces them to become fruitful; but if they continue to grow very strongly they are root pruned occasionally, so as to keep them in good bearing condition.

GERMINATION OF SEEDS.

THE student will do well to watch with care the various stages of the act of germination, as exhibited in several species of plants. For this purpose a dozen or more seeds of each plant are sown—the smaller kinds of seed,  $\frac{1}{2}$  inch, the larger, 1 inch deep—in a box of earth or sawdust, kept duly warm and moist, and one or two of each kind are uncovered and dissected at successive intervals of twelve hours until the process is complete. In this way it is easy to trace all the visible changes which occur as the embryo is quickened. The seeds of the Kidney-Bean, Pea, Maize, Buckwheat, and Barley, may be employed. We thus observe that the seed first absorbs a large amount of moisture, in consequence of which it swells and becomes more soft. We see the germ enlarging beneath the seed coats; shortly the integuments burst and the radicle appears; afterwards the plumule becomes manifest. The endosperm, if the seed have one, and in many plants the cotyledons (as with the Horse-Bean, Pea, Maize, and Barley), remain in the place where the seed was deposited. In other plants (Kidney-Bean, Buckwheat, Squash, Radish, &c.) the cotyledons ascend and become the first pair of leaves. In the former case the rudimentary stem or radicle scarcely elongates at all; in the latter it grows through its whole length, and elevates the cotyledons above the soil. The ascending plumule shortly unfolds new leaves, and, if coming from the seed of a branched plant, lateral buds make their appearance. The roots are formed at the other end of the radicle. When the plantlet ceases to derive nourishment from the mother seed, the process is finished. As to the conditions of germination, we have to consider in detail the following:—

TEMPERATURE.

A certain range of warmth is essential to the sprouting of a seed. Göppert, who experimented with numerous seeds, observed none to

germinate below 1°. Sachs has ascertained for various agricultural seeds the extreme limits of temperature at which germination is possible. The lowest temperatures range from 5° to 13°; the highest, from 39° to 17°. Below the minimum temperature a seed preserves its vitality; above the maximum it is killed. He finds, likewise, that the point at which the most rapid germination occurs is intermediate between these two extremes, and lies between 26° and 31°. Either elevation or reduction of temperature from these degrees retards the act of sprouting. In the following table are given the special temperatures of germination for six common plants:

	Lowest Temperature.	Highest Temperature.	Temperature of most rapid Germination.
Wheat ... ..	5° C.	49° C.	29° C.
Barley ... ..	5	49	29
Pea ... ..	7	39	29
Maize ... ..	9	46	31
Scarlet-Bean ... ..	9.5	44	26
Squash ... ..	12	46	31

For all agricultural plants cultivated in England, a range of temperature of from 13° to 32° is adapted for healthy and speedy germination. It will be noticed in the above table that the seeds of plants introduced into northern latitudes from tropical regions—as the Squash, Bean, and Maize—require and endure higher temperatures than those native to temperate latitudes, like Wheat and Barley. The extremes given above are by no means so wide as would be found were we to experiment with other plants. It is probable that some seeds will germinate nearly at 0°, or the freezing-point of water, while the Cocoa-nut is said to yield seedlings with greatest certainty when the heat of the soil is 49°. Sachs has observed that the temperature at which germination takes place materially influences the relative development of the parts, and thus the form of the seedling. According to this industrious experimenter, very low temperatures retard the production of new rootlets, buds, and leaves. The rootlets formed directly from the embryo become, however, very long. On the other hand, very high temperatures cause the rapid formation of new roots and leaves, even before those existing in the germ are fully unfolded. The medium and most favourable temperatures bring the parts of the embryo first into development, at the same time the rudiments of new organs are formed which are afterwards to unfold. The vitality of some seeds has been found not to be destroyed by a cold of -18°; nor by a dry heat of 75°.

MOISTURE.

A certain amount of moisture is indispensable to all growth. In germination it is needful that the seed should absorb water, so that motion and solution, and in consequence chemical action, can take place in the contents of the germ-cells. Until the seed is more or less imbued with moisture, no signs of sprouting are manifested, and if a half-sprouted seed be allowed to dry, the process of growth is effectually checked, and, in many cases, the vitality lost. The degree of moisture different seeds will endure or require is exceedingly various. The seeds of aquatic plants naturally germinate when immersed in water. The seeds of many land plants, indeed, will quicken under water, but they germinate most healthfully when moist but not wet. Excess of moisture often causes the seed to rot.

OXYGEN GAS.

Free oxygen, as contained in the air, is likewise essential. Saussure demonstrated by experiment that proper germination is impossible in its absence, and cannot proceed in a vacuum, or in an atmosphere of other gases. As we shall presently see, the chemical activity of oxygen appears to be the means of exciting the growth of the embryo.

LIGHT.

It has been stated that light is prejudicial to germination, and that therefore seeds must be covered (Johnston's Lectures on Agr. Chem. and Geology, 2nd Ed., pp. 226, 227). When, however, we consider that nature does not bury seeds, but scatters them on the surface of the ground of forest and prairie, where they are, at the most, half-covered, and by no means removed from the light, we cannot wholly accept this. The warm and moist forests of tropical regions, which, though shaded, are by no means dark, are covered with sprouting seeds. The gardener knows that the seeds of Heaths, Calceolarias, and some other ornamental plants, germinate best when uncovered, and the seeds of common agricultural plants will sprout when placed on moist sand or sawdust, with apparently no less readiness than when buried out of sight. Finally, R. Hoffmann (Jahresbericht über Agrikultur Chem. 1864, p. 110) has found in experiments with twenty-four kinds of agricultural seeds that light exercises no appreciable influence of any kind on germination.

THE TIME REQUIRED FOR GERMINATION.

The time required for germination varies exceedingly, according to the kind of seed. As ordinarily observed, the fresh seeds of the

Willow begin to sprout within twelve hours after falling to the ground. Those of Clover, Wheat, and other grains germinate in three to five days. The fruits of the Walnut, Pine, and Larch lie four to six weeks before sprouting, while those of some species of Ash, Beech, and Maple are said not to germinate before the expiration of one-and-a-half or two years. The starchy and thin-skinned seeds quicken most readily. The oily seeds are in general more slow, while such as are situated within thick and horny envelopes require the longest periods to excite growth. The time necessary for germination depends naturally upon the favourableness of other conditions. Among these conditions we may name the age of the seed and its percentage of moisture, the nature of the soil in which it is sown, and the presence or absence of certain chemical compounds. Many metallic salts arrest or retard germination; on the other hand, very weak chlorine-water accelerates the process. Cold and drought delay germination, when they do not check it altogether. Seeds that are buried deeply in the soil may remain for years, preserving, but not manifesting, their vitality, because they are either too dry, too cold, or have not sufficient access to oxygen to set the germ in motion. To speak with precision, we should distinguish the time from planting the dry seed to the commencement of germination—which is marked by the rootlet becoming visible, and the period that elapses until the process is complete, *i.e.* until the stores of the mother-seed are exhausted, and the young plant is wholly cast upon its own resources. At 5 in the experiments of Haberlandt, the rootlet issued after four days in the case of Rye, and in five to seven days in that of the other grains and Clover. The Sugar-Beet, however, lay at this temperature twenty-two days before beginning to sprout. At 11° the time was shortened about one-half in case of the seeds just mentioned. Maize required eleven, Kidney-Beans eight, and Tobacco thirty-one days at this temperature.

#### PROPER DEPTH OF SOWING.

The soil is usually the medium of moisture, warmth, &c., to the seed, and it affects germination only as it influences the supply of these agencies; it is not otherwise essential to the process. The burying of seeds when sown in the field or garden serves to cover them away from birds and keep them from drying up. In the forest, at spring-time, we may see innumerable seeds sprouting upon the surface, or but half covered with decayed leaves. While it is the almost universal result of experience in temperate regions that seeds germinate most surely when sown at a depth not exceeding 1 to 3 inches, there are circumstances under which a widely different practice is admissible, or even essential. In the light and porous soil of the gardens of New Haven, Peas may be sown 6 to 8 inches deep without detriment, and are thereby better secured from the ravages of the domestic pigeon. The Moqui Indians, dwelling upon the table lands of the Colorado, deposit the seeds of Maize 12 or 14 inches below the surface. Thus sown, the plant thrives, while, if treated according to the plan usual in the United States and Europe, it might never appear above-ground. The reasons for such a procedure are the following:—The country is without rain, and almost without dew. In summer the sandy soil is continuously parched by the sun at a temperature often exceeding 38° in the shade. It is only at the depth of a foot or more that the seed finds the moisture needful for its growth—moisture furnished by the melting of the winter's snow.\* R. Hoffmann, experimenting in a light loamy sand upon twenty-four kinds of agricultural and market-garden seeds, found that all perished when buried 12 inches. When planted 10 inches deep, Peas, Vetches, Beans, and Maize alone came up; at 8 inches there appeared, besides the above, Wheat, Millet, Oats, Barley and Colza; at 6 inches those already mentioned, together with winter Colza, Buckwheat, and Sugar-beets; at 4 inches of depth the above and Mustard, red and white Clover, Flax, Horseradish, Hemp, and Turnips; finally at 3 inches, Lucerne also appeared. Hoffmann states that the deep-planted seeds generally sprouted most quickly, and all early differences in development disappeared before the plants blossomed. On the other hand, Grouven, in trials with Sugar-Beet seed, made, most probably, in a well-manured and rather heavy soil, found that sowing at a depth of  $\frac{1}{2}$  to 1 $\frac{1}{2}$  inches gave the earliest and strongest plants; seeds deposited at a depth of 2 $\frac{1}{2}$  inches required five days longer to come up than those planted at  $\frac{1}{2}$  inches. It was further shown that seeds sown shallow in a fine wet clay required four to five days longer to come up than those placed at the same depth in the ordinary soil. Not only the character of the soil, which influences the supply of air, and warmth, but the kind of weather which determines both temperature and degree of moisture, have their effect upon the time of germination; and since these conditions are so variable, the rules of practice are laid down and must be received with a certain latitude.—“*How Crops Grow.*”

\* For these interesting facts the author is indebted to Professor J. S. Newberry.

## THE PLANTING OF THE LONDON SQUARES.

### THE PLANES IN MECKLENBURGH SQUARE.

IN “Squares” where the space enclosed by houses is of sufficient size, large trees produce a very fine effect; and some kinds, if well planted, thrive with sufficient luxuriance, notwithstanding the smoky atmosphere, to render the embellishment of every available space, even in the densest parts of the metropolis, with the pleasant aspect of masses of foliage, by no means a hopeless undertaking. Deciduous trees of hardy character, and such as are able to resist the impurities of the London atmosphere, are the best suited to such situations; evergreens having been found, since the vast increase of smoke-emitting chimneys, quite unequal to the contest with the soot of the great city. When our celebrated horticulturist, Loudon, first came to London nearly three quarters of a century ago, as an enterprising young Scotsman seeking his fortune, he at once scanned with the keen eye of an enthusiastic landscape gardener our attempts at keeping up the illusion of a little refreshing greenery in and among our great wilderness of brick and mortar; and, clearly perceiving that the effort to keep the plantations of the squares attractive in winter as well as summer, by means of evergreens, was a failure, he at once denounced the futility of planting Spruce Firs, Yews, Laurels, Boxes, Arbor-vites, and, indeed, all such evergreens as he found in common use. His remarks were so well founded, that they attracted almost immediate attention, and were evidently acted upon with very little delay, for the planting of nearly all the finest deciduous trees which now ornament our squares took place about that time. When speaking on this subject in after years, Loudon used invariably to bring forward, in support of his theory that evergreens will not live in London smoke, the following illustrative anecdote:—There was a time, he would say, when not one of the scores of churchyards within the precincts of the City was without its Yew trees—young or old—some of them, doubtless, of great antiquity, and many of more recent date; but, in consequence of the introduction of coal fuel, and the vast, though gradual, increase of coal fires, not one of those Yew trees, not a single one—young or old—is now to be found; while in the surrounding villages, wherever they are sufficiently distant to be out of the reach of foliage-killing soot deposits, there are venerable Yews, still in a vigorous, green old age, that date from the times of the Heptarchy. Now, had the trees sacred to churchyards happened to be deciduous trees, such as the Planes, the Elms, and several others, which, to a certain extent, defy the blighting influence of the metropolitan smoke, many of them might have been still in existence at the present day, notwithstanding the ever-increasing number of smoke-breathing chimneys.

The big Planes of Mecklenburgh Square, represented in our engraving, bear witness to the smoke-defying powers of that noble tree; and there are other deciduous trees in the same enclosure which seem, Mark Tapley-like, to be enjoying themselves amazingly under the murky circumstances. It having been ascertained that the Plane and several other kinds of handsome deciduous trees will thrive well in our squares, the next consideration is, how to plant them with the greatest advantage, in reference to such situations as those of the railed-in spaces of our town squares. There are some undeniable advantages in planting them next the railings. For instance, during the heat of a London summer, when at mid-day the pavements, heated by the full glare of the sun, get so hot that they seem to scorch the soles of one's feet, like the scoriae of Vesuvius round about the crater, large trees close to the railings of a square cast their broad shadows across both foot-path and carriage-way, and make it far pleasanter walking or riding in the comparative coolness of the chequered shade. But then, on the other hand, by planting trees and shrubs immediately within the railings, the view of the interior of the square is shut out from the public; and then arises the question whether the plantation is to be considered as existing only for the advantage of the inhabitants of the surrounding houses, or whether, in so far as a good view of it is concerned, the enjoyment of the public ought, or ought not, to be considered.

If, instead of a dense hedge of shrubs, flower-beds and

LARGE PLANE TREES IN MECKLENBURGH SQUARE.

turf were made to occupy a broad belt of space near the railings, they would form very pleasing objects, and be in full view to every passer-by who might pause and admire them, and experience a pleasant, if but a momentary, sensation, in the haste of his bustling rounds on those hard matters which concern the daily business of life. It would seem that this would not very much interfere with the rights and privileges of those who had the *vue* of the interior, and one would think that on humanitarian principles they could not object to it. Supposing this arrangement of turf and flowers carried out in a broad strip of the space next the railings, the large trees might be made to form a noble irregular group in the centre, with one or two isolated Planes picturesquely placed in different positions, not so far from the central masses as to produce a spotty effect. This general arrangement of the plantation of a square, varied according to circumstances, could not fail to produce pleasing results. It might also be modified to some extent by planting the larger trees (without accompanying shrubs) next the railings, so as still to throw their pleasant shades over portions of the roadway; but not allowing any dense shrubs in that situation, as seen in our engraving, in which position they entirely obscure the view of the interior. By their removal the trunks of the larger trees would not seriously impede the view across the enclosure, which would be seen beneath their branches, the lowest of which would almost in every case be above the eye line of the spectator. The central mass might then be formed of an irregular group of shrubs of moderate height, and round about it a broad border of flowers; and there might also be a few detached flower-beds in such well-selected situations as would be free from the shadow of the large trees next the rails. In short, many successful methods of planting the squares might be adopted, almost any of which would be preferable to the poor and uninteresting arrangements that generally prevail.

## THE LIBRARY.

### THE ORCHARDIST.\*

This is a volume with which every gardener should be acquainted, and which is, in its way, unique among English publications. It contains descriptions of all our hardy fruits, and much other cultural and interesting matter about them. The following extract will show the practical nature of the work; but it is for its capital descriptions of all the really useful kinds of hardy fruits that it will be chiefly valued.

#### MAKING AN ORCHARD.

It will, perhaps, be of service to some if I here give a few hints on making and planting an Apple orchard. To succeed well in forming a good orchard, it is necessary that the soil be of such a nature that the Apple may grow in it freely; and, if it is not naturally good, it ought to be made so by artificial means, as the size and flavour of the fruit will depend upon the health and vigour of the trees. Trenching the ground is the method generally resorted to for improving the staple of the soil; but, where this is necessary, it ought not to be done too deeply; it is better to add to the surface a sufficient depth of such earth as may be required, and then to dig the whole deeply, taking care to plant the trees on a slight elevation or mound, which will contribute much to their health and strength. Climate, situation, &c., affect fruit trees, but not generally to such an extent as the soil—if that is not genial, no climate or site will be of any avail. The soils in this locality, where the best cider is made, are of strong alluvial deposit, with naturally well-drained or porous subsoil, such as neither wet nor drought affect much. If the ground intended for orcharding is not naturally in that condition, it ought to be made as nearly like it as possible by deep digging, manuring, and draining, and, in the case of light soils, the addition of some good strong clay; for when the soils are too light, a thin watery cider can only be obtained, and a great depth of soil is not so essential as that it be strong, good, and well drained. With the Apple, as with all other fruit trees, the nearer the surface the roots can be induced to run, so much the better chance of well-ripened wood, without which all cultivation will be nearly thrown away. Short, firm, well-ripened wood should be the great object aimed at; if this be obtained, the

fruitful result will follow. The situation for an orchard should not be in too low-lying ground, in valleys, or near rivers or streams of water. Such are generally unsuitable places, as the vapours arising from them in the night get condensed upon the cold foliage and flowers of the trees; and, should frost follow in the morning, which it frequently does at the blossoming season, then the young embryotic fruit runs great danger of getting cut off. Such situations should, therefore, be avoided as much as possible. On the other hand, if the trees are planted upon too high or exposed places, then they are subject to have their crops blown off before they become ripe, and are in that way rendered useless. Gently-swelling hills and slightly-elevated places facing the S.E., S., or S.W. are the best, especially if sheltered from the N. and N.E. winds. After your soil, &c., has been properly prepared, it will be necessary to procure the sorts of fruit trees you wish to grow from some well-known respectable nurseryman, to whom it is generally the best plan to state what form of tree you require, leaving to him the selection of sorts. If he is a good pomologist, he will be able to advise you better than if you were to make a haphazard choice of your own. On receiving trees from the nurseries, never leave the roots exposed an instant; and, on purchasing, bargain to have them well secured from dry and cutting weather, for hundreds of fine trees are annually so injured by injudicious exposure, that they require years for their recovery. Farmers, I may say, are generally remiss on this point, hence the numerous complaints about trees not doing well. I never allow a tree to have its roots exposed above a few minutes. When taken up for sale, they are carried immediately to the packing shed and the roots at once secured. If the purchaser were equally careful, we should hear of very few trees doing badly.

The best season for planting an orchard is October or November—the earlier in autumn the better; if the work is delayed until spring, a year is lost. Therefore say, from my own extensive experience, plant early in autumn; but be sure, when you select your trees, that you bargain with the nurseryman to pluck off all the leaves as soon as the trees are taken up. This simple precaution will prevent the bark shrinking and evaporation of the sap, so that the tree, when planted again, will not require to draw so much from the soil at first, before it has had time to develop fresh roots. I have for many years practised this system of defoliation, and have always found it useful in promoting the early rooting of the trees. In my experience as a nurseryman, I have always found it beneficial to take up my trees and lay them in by the heels some time before planting again. The rationale of this is that the trees get gradually accustomed to less nourishment, and therefore, when replanted, easily obtain enough to support them. By so laying them in scarcely one in a thousand will die; whilst, on the other hand, trees freshly lifted, and immediately transplanted, will have a great many deaths amongst them. In 1860 I had some thousands of *Pinus austriaca* to plant. A great portion of these, about one-half, had been taken up and laid in by the heels for several weeks, while the other portion were taken up and at once planted along with those which had been laid in, although separate from them; the result was that the laid-in trees all lived, and half of the fresh transplanted ones died! This is one instance; but such cases are constantly recurring in a nursery, and the same thing happens in forming plantations where the planter uses trees just freshly lifted. It is always best to have the trees left heeled in, or to have their roots covered up for a while with any shot damp litter before replanting; I am certain it would save many hundreds that would otherwise die. Apple trees, of course, are best treated in the same way. Always avoid deep planting, especially in cold or damp soils. Raise the tree upon a little mound in such soils; in fact, it is best to do so in any kind of soil. In planting orchards, it is necessary to have the holes or pits into which the trees are to be put somewhat wider than the roots extend, so that these last may be spread out evenly and horizontally: this will tend in a great measure to prevent their rooting too deeply, and will also promote fruit-bearing by causing the branches to be better ripened, and the fruit-buds to be better matured.

UNDER the title of "Herbarium Mycologicum Economicum," Herr F. Baron Thümen, of Teplitz (Bohemia), advertises the commencement of an extensive collection of dried Fungi, especially of such parasites as are injurious to cultivated plants. He considers it very desirable that a better knowledge of these enemies should be disseminated in this way amongst horticulturists, while he proposes that the collection shall ultimately include every species of Fungus, edible or otherwise. These dried specimens are offered for sale at the rate of 3 thalers (9s.) per fascicule of 50 species, and can be obtained only by sending the amount to the collector, at the above address. The first instalment of the collection will not be ready for distribution before the latter end of this year.

\* The Orchardist. By J. Scott, The Nurseries, Merriott, Somerset.

LIME-KILN HEATING.

As you are aware, the idea of heating hothouse boilers by means of a lime-kiln is not altogether new. We have worked one here successfully for nearly four years. When I say *successfully*, I mean comparatively so—that is to say, we managed to do our heating 50 or 60 per cent. cheaper than when we burned only round coal. As to having the fire free of cost, I do not think it possible—in this locality, at all events. The kiln we have worked hitherto is 3 feet 6 inches diameter, and 12 feet high. The boiler—a horizontal tubular one—is 4 feet high, and encircles the kiln near the top. This kiln consumes,

wall rises about 2 feet. The boiler weighs just 3½ tons, and will, I hope, be sufficient to heat at least 5,000 feet of 4-inch pipes. To put up such a kiln as this, you must have your houses placed on the summit of a rising ground of at least 20 feet.

RICHARD COLLES.

Millmount, Kilkenny.

SOILS, MANURES, &c.

NEW METHOD OF ENRICHING STERILE SOILS.

Many horticulturists believe that it is impossible to grow plants in a sterile soil by means of artificial food composed of mineral substances dissolved in water. In a recent notable essay, a translation of which is presented by the *Chemical News*, M. J. Jeannel maintains (and he bases his conclusions on the results of experiments) that (1) nitrates or nitrites are naturally formed in soil containing organic vegetable matter when in contact with air. (2) That it is possible to feed plants with solution of mineral compounds suitably prepared, so that the plants receive from these solutions the mineral constituents they require, and may thus grow more vigorously even in pure sand than in the best garden mould. This opinion was put forth in 1856 by Boussingault, while experimenting on the growth of Helianthus. The eminent savant then said that the plant assimilates the mineral substances, and need not necessarily be placed in a soil containing decaying organic matter. And this opinion is also strengthened by the experiments of M. Ville, which prove the importance of chemical manures in agriculture. M. Jeannel states that he has utilized the views of Boussingault, Millon, and Schœnbein on the natural production of the oxygen compounds of nitrogen; and at the same time has modified them to some extent. He first studied the natural conditions of the formation of nitrates in arable soil, without the intervention of ammonia, simply from the elements of air and the reduction of these nitrates by humus. He applied Schœnbein's re-agent (solution of iodized starch acidulated with sulphuric acid), which strikes a blue colour in the presence of nitrates. By the aid of this re-agent he ascertained the following facts:—

When arable soil or garden mould is well washed in a displacing apparatus with pure distilled water, that fluid always exhibits the presence of nitrites. It is, however, necessary to use—for the complete removal of the nitrites from the soil—about twelve times the quantity by weight of distilled water to the weight of the soil experimented upon. The soil thus treated having been again dried, yields, after a short time, nitrites, as indicated by Schœnbein's test in the water employed a second time for exhausting the soil. Sandy soils, and all those which do not effervesce when treated with acids, do not recover nitrates after being dried unless carbonate of lime is added, and the soil then moistened with water and again dried, and lastly washed with distilled water, which then exhibits the reaction for nitrates.

When a solution of the nitrates of potassa and ammonia at 5.1000 is made to pass through the arable soil or garden mould, previously well washed with water, the soils being placed in a displacement apparatus, it will be found (as I also ascertained) that the nitrates are retained in the soil. One kilo (2¼ lbs.) of the soils—which require to be moistened with about half their weight of water—retains about four-fifths of the soluble salts contained in the first litre (1½ pint) of the saline solution at 5.1000, which is poured on to the soils. Nitrate of ammonia is retained by the soil in larger proportions than nitrate of potassa. The alkaline nitrates are, in twenty-four hours, reduced to nitrites when in contact with dead leaves, straw, or humus. That reduction is so marked that, when dead leaves are washed with distilled water, the leaves distinctly exhibit, with Schœnbein's reagent, the presence of nitrites, due to the nitrates naturally present in the well-water of Paris.

These facts appear, in the judgment of M. Jeannel, to lead to the following conclusions:—

(1.) Soils containing humus and lime determine, while drying, the combination of the elements of the air, without any intervention of ammonia, so that either nitric or nitrous acids are formed, which are at once fixed by the lime. This explains, not only the sterility of soils void of lime and of peat-bogs, but also the utility of liming the soils.

(2.) The nitrate of ammonia contained in rain-water and in dew (Millon and Schœnbein) is retained by the humus in the upper layer of the soil, with the nitrites constantly formed in the well-aerated and limed soil, according to the conditions of the atmospheric moisture or dryness.

(3.) This constant formation and renovation of the oxygen compounds of nitrogen in soil containing lime and humus is a fact of great importance, which explains the exceptional fertility of the soil in alternate wet and dry weather, when frequent showers of rain

Mr. Colles's Lime-Kiln Boiler.

on an average, 2 tons of culm per week, and 3 tons of stone; it produces about 24 barrels of lime. The net expense is easily calculated:—

	£	s.	d.
Two tons of culm (at 8s. 6d.)	...	...	0 17 0
Three tons of stone (at 1s.)	...	...	0 3 0
Attendance three days (at 2s.)	...	...	0 6 0
	£1	6	0
Twenty-four barrels of lime (at 7d.)	...	...	0 11 0
Gives net cost per week	...	...	£0 12 0

(Or about 1s. 9d. per day.)

This kiln, we find, is able to heat 1,000 feet of 4-inch pipes sufficiently for ordinary forcing purposes. As we are heating over 2,000 feet of pipes at present, we were obliged to supplement it this spring with an ordinary 3-foot tubular boiler. This determined us to put up a larger kiln, which is now nearly finished, and of which the accompanying is a sketch. The height of the boiler is 7 feet, the diameter at the top 3 feet 6 inches, at the bottom 4 feet 6 inches. The entire height of the kiln, from the bottom of the ash-pit to the top of the brick-work, is 15 feet 6 inches; above this the external

are followed by great heat, as was the case in 1872 (in France, at least). It also, in connection with the great affinity of the humus of soluble salts, more especially ammoniacal, accounts for the accumulation of fertilising principles in fallow lands, and at the same time shows the utility of mechanical operations in the soil, such as ploughing, digging, harrowing, &c., by which means contact with the air is increased and free access of air promoted.

M. Jeannel endeavoured to elucidate these theories by a series of horticultural experiments, specimens of the results of which he forwarded to the French Academy with the subjoined explanations:—

I. *Comparison between plants grown in sand and in garden mould.*—The plants placed in sand have been supplied every week, in addition to receiving ordinary water, with a solution of a few grains of mineral manure dissolved in water. The plants placed in garden mould have only had common water. The pots were placed on saucers, in order to prevent loss of soluble salts. I exhibit, as specimens of this experiment, two plants of the *Pelargonium zonale* and two of the *Agave corniculata*, which in April last were all in the same stage of development. The *Pelargonium* grown in the sand is four times as much developed as that grown in garden mould, and has been constantly in bloom during the summer; the *Agave* grown in the sand is twice as large as that grown in the garden mould.

II. *Plants grown only in sand; but some watered with common water only, others with the mineral solution once a week.*—I exhibit here, as specimens, several *Arum italicum*, and state that I have, during the summer, made a large number of similar experiments with plants belonging to different natural families, such as *Begonias*, *Tradescantias*, *Veronicas*, &c. The plants grown without the addition of mineral manure are either dead or drooping, while those raised with the addition of that manure have grown magnificently.

III. *Plants grown only in garden mould, to some of which only common water has been given, and to others, in addition to that fluid, a quantity of mineral solution has been supplied weekly.*—As a specimen of the result of this experiment, I exhibit two specimens of *Sedum acre*, the plant which has received weekly three grains of the mineral manure solution having grown twice as much as the other.

IV. *Plants which have remained for two consecutive years in the same soil in pots.*—These, as far as they have been treated with my mineral manure, have grown so well that their size is altogether out of proportion with the pots which contain them. As samples I exhibit an *Aspidistra elatior* and an *Arum esculentum*.

The mineral manure which I use is made up according to the results of elementary analysis of farm-yard and other manure, taking into consideration that the arable soil, containing organic matter, acts constantly as a nitre bed, and thus fixes the elements of the air into combination. The manure consists of the following ingredients:—

Nitrate of ammonia . . . . .	400 parts
Nitrate of potassa . . . . .	250 parts
Biphosphate of ammonia . . . . .	200 parts
Chloride of ammonium . . . . .	50 parts
Sulphate of lime (gypsum) . . . . .	60 parts
Sulphate of iron . . . . .	40 parts

Total . . . . . 1,000

The salts should be pulverised separately, and then intimately mixed. I apply this manure in the following manner:—Dissolve 62 grains in  $1\frac{1}{2}$  pint of water; give to the plants, according to their state of development, every week from  $\frac{1}{2}$  lb. to 3 lbs. of this solution (equal to from  $1\frac{1}{2}$  gr. to 9 grs. of the salt in solid state). The compound costing at the rate of 1s. per lb., the minimum yearly expense of thus manuring a plant would consequently be only a little over a farthing, while the maximum cost would not exceed 3d.

Conclusions.—(1.) Plants can be fed by means of artificially made mineral solutions. (2.) Horticulture may greatly profit by this mode of growing plants, because it renders repotting unnecessary, and because the nature of the soil becomes a matter of entire indifference, provided it offers to the plants a proper and sufficiently permeable hold; while, lastly, the plants can be fed at will and when most convenient.

**Application of Fibre of Agave.**—One of the most recent applications of *Agave fibre* seems to be in the manufacture of a kind of square bag or basket, which was first seen a year or two since in toy shops, principally in the seaside towns. They have now become very general, and can be had at almost every hardware and toy shop. They are made chiefly of the twisted fibre of *Agave americana*, the principal part being of its natural colour, but a portion is dyed black, and worked in with it. Whether the fibre is prepared in this country into the fine strong cord of which these bags are made, whether the bags themselves are made here, and whether other strong fibres are used, are questions which some readers may be able to answer. There is, in the Kew Museum, a bag made of New Zealand Flax, which is similar in shape and size to those usually sold, but the material is not so closely worked.—*Journal of Botany.*

## THE HOUSEHOLD.

### CULTIVATING THE MOREL.

(*MORCHELLA ESCULENTA.*)

BEING particularly fond of the odour of the Morel, the scent of which is almost as delicate as that of the Truffle, I decided, a few years ago, to establish a bed on my property in the country, and to cultivate the Morel in the same manner in which we cultivate our ordinary Mushroom (*Agaricus campestris*). I made up the bed in the following manner:—Two-fifths consisted of the manure of well fed horses, two-fifths of earth rich in ammonia, and one-fifth rotten wood. The bed being thus formed, I sowed it with fragments of Morels which I had gathered; but I was disappointed with the result. The bed being in a dark cellar was overrun by some *Agaric*, and I had only five Morels. I was not, however, discouraged; on the contrary, I replaced a fifth of the manure by a fifth of earth taken from the spot where I had gathered the Morels. The following year I obtained nearly 32 lbs. off a space of about eleven and a half feet square. The bed came into bearing about the first of April and lasted until the middle of July. After this I only found one or two now and then. The year after that the bed commenced to produce at the same time as the previous season, and proved sufficiently productive to more than remunerate me for the slight expense I was at in forming and maintaining it. I thought that after the third season the bed would be exhausted, so I made a fresh one on the same plan as the former ones, on which I sowed the fibrous germs which were found at the lower part of the Morels gathered from my last bed. I selected the small brown Morel for my beds in preference to the white one, which is larger, but whose scent is less delicate. The Morel, like the ordinary Mushroom, should be grown in darkness; but it requires more water than the common Mushroom, which must not, however, be allowed to remain for any length of time in the bed. To prevent this, I placed two wicker hurdles under the bed (which is only six inches thick), so as to enable the water to drain quickly from it. The water must also be carefully applied by means of a watering pot furnished with a fine rose. Morels may be easily dried and preserved without losing their fragrance, thus rendering continual production unnecessary. String them by the stems and hang them up in some dry place. Morels are very expensive, but they may be easily obtained and made more common by following the plan of culture just described, and they make as delicate a dish as the Truffle itself.—*Laurent Geslin.*

**St. George's Mushroom (*Agaricus gambosus*).**—This delicious agaric, so well known in both France and Italy, occurs with us just now somewhat abundantly on the oolite. It affects fairy rings in the spring of the year, much as others do in the autumn. I will describe its aspect and habits of growth, so that even a novice may recognise it and not fear to use it, as offering a delightful and palatable dish. Very soon after St. George's Day the *moisteron* makes its appearance, and early in May its white caps may be seen peeping through the Grass. Its favourite growth is in rings, and sometimes a partial circle, sometimes a whole circle, may be traced by this agaric. The cap, as I said, is white, inclining to a buff, variously contorted, constricted by the roots and strong fibres of the Grass through which it forces its way. It clings somewhat closely to the sward, seldom rising in the early spring more than an inch above it. The cap, or pileus, is soft to the touch, and smooth. Here and there in the older caps a crack may be seen; that is a very characteristic marking in this agaric. The gills are at first pale, but age changes them to a light brownish hue as the fungus attains maturity. The stalk is thick and dumpy, and shows a tendency to the bulbous in a young stage of the Mushroom. The smell is strong, like the smell on entering a mill where Wheat is ground. These indices ought to enable anyone to recognise it at a glance, and, as it oft appears long before any other kind, there ought to be no difficulty or doubt felt about it. It may be cooked like the ordinary Mushroom, but it requires nearly an hour's cooking to render it tender and palatable.—*PETER INCHBALD, Hovingham, near York, in "Field."*

**Rhubarb Fool.**—Cut the stalks into short lengths, then put them in a jar into the oven to draw out the juice. When that is done pour it through a hair sieve to strain into a basin, and when cold take as much of the juice as you require, mix with milk and sugar, and proceed the same as with Gooseberry fool.—S.

**How to Bake an Apple.**—To bake an Apple perfectly can only be done by giving it time, keeping it under heat—steady at that—for from four to six hours, depending upon the size and quality of the fruit. It requires this length of time to reduce it to a fine pulp and destroy all rawness. The flavour is changed and improved, making, if the Spitzenburg or some other good fruit, one of the choicest and daintiest of dishes. The point in baking is to give all the heat that can be borne without bursting the skin, thus retaining the moisture.—F.

CHURCHYARD GARDENS.

A MOVEMENT has already set in in favour of planting the churchyards of our great towns and cities; but such planting is not always done with that degree of good taste which would ensure success. There are, for instance, a few trees scattered round St. Paul's; neither in the selection of the kind of trees, nor in their grouping or position, is there the slightest attempt to produce any of those pleasing effects which may be so easily achieved by a judicious combination of foliage with architecture. There can be no doubt that the beauty of the magnificent architecture of our great metropolitan cathedral might be considerably enhanced by a little tasteful planting, especially in the open space before the west front at the top of Ludgate Hill, and yet nothing whatever is attempted.

The position of La Trinité des Monts, at Paris, of which a spirited cut is here given, is somewhat analogous to that of our St. Paul's, and there is a detached group of statuary in front occupying a similar position to that filled by the statue of our good Queen Anne. The conditions being similar, why should not the combination of effects to be achieved by judicious planting be made equally effective and pleasing in both? At La Trinité well designed bands of turf are made to contrast their bright and lively green with the cool grey of the architecture, which serves as a charming monotone background to the gorgeous colours of the flowers, of which great masses vary the expanse of the soft green turf. Trees then begin to play their part, not blocking up the central view, but shading it off on either side, and pleasingly interrupting the continuous rigidity of the architectural lines, or the formal ornamentation of the stone carvings by the ever graceful irregularities of nature. The pleasing effects of a combination of architecture and foliage have been largely appreciated by many, though in most cases without seeking to define the nature of the combination by which the pleasing impression had been brought about. Such effects have, in fact, been in most instances in England the result of accident. On the building of a country mansion, for instance, it would be difficult to point to many examples in which trees have been designedly planted near the house with the view of creating a pleasing combination of art and nature by the studied juxtaposition of the architectural forms and the grouping of foliage. It is true that scores of examples exist in park scenery, of magnificent effects of woods, slopes, and water, which frame in a mansion very magnificently; but they have either been the result of accident, or the park and the mansion have been two utterly distinct works, which, however, from the nature of things, could not under any circumstances prove altogether unsuccessful. But the planting of trees about town buildings is a somewhat different matter; and, to achieve a success such as that of the plantations of the Church of La Trinité, requires a special kind of study, without which good results cannot be expected. I have said that the relative positions of La Trinité and St. Paul's bear considerable analogy to

each other; and, that being the case, it seems natural to ask why the surroundings of St. Paul's should not be made equally attractive by a little similarly careful planting of a suitable kind; which should of necessity be bold and stately in its character, in order to accord with the grandeur of the building itself. For instance, let us suppose the statue of Queen Anne to be considerably raised, on a highly decorative base, and let it be combined with a pair of magnificent fountains, of which the statue would form the central and most elevated object. Let the group of objects so formed be surrounded by an expanse of turf of corresponding outline, which should be bordered, within a low but massive stone coping, by a bold band of richly-coloured flowers. On either

side of a broad paved or gravel walk, wide expanses of turf might be established, in which the judicious planting of groups of trees should be effected in such a way as would shut out, to a great extent, the view of the ignoble buildings which, on either side, crowd far too closely on the masterpiece of our greatest English architect, while, at the same time, they would soften, without concealing, the necessary formalism of the glorious mouldings, and ornaments, and statuary of the great cathedral, as the juxtaposition of the pleasing irregularity and untrained ramification of the branches of graceful-growing trees never fail to do.

It is to be hoped that, while so much is now on the tapis with regard to the decoration and completion of the interior of the building, that the necessary attention will also be bestowed on improving its external aspect by some such additions as those suggested. THE GARDEN has already hinted at the creation of a cathedral garden round about St. Paul's, but it is difficult for such a cry to reach official ears, deadened as they are by the dull routine of daily business; while official eyes are so dimmed with the worry of examining the hum-drum plans and proposals of daily necessity, that it is difficult to make such ears hear, or such eyes see, anything out of the beaten track of official drudgery; and one could scarcely expect it to be otherwise. NOEL HUMPHREYS.

Garden and Church of La Trinité des Monts, Paris.

**Lime Concrete Walls and Walks.**—These are made by mixing sifted sand with quick-lime, in the proportion of about fifteen to one, and thoroughly working them together with a hoe, occasionally sprinkling the heap. The mixture is then thinly spread upon the ground, and beat very solid with a kind of wooden peel, now and then wetting the place to assist the solidification. The materials for walls should be the same, but the gravel should be rather coarser. In constructing a wall boards should be set within posts on each side of the foundation just the thickness of the intended wall, and the gravel poured in, and pounded down solid with long heavy beaters. When full to the top of the boards, additional ones should be placed above them, and the process repeated till, by successive increments, the wall is finished. When thoroughly dry, it should be coated with coarse plaster for preservation from rain, and if the coating is well done, the wall becomes in time very hard and stony.

## THE KITCHEN GARDEN.

### GARLIC.

THIS, though a native of the Mediterranean region, has all the vigour of the hardiest and strongest northern herbs, and, though flourishing best in a dry fertile soil and warm situation, it will do almost anywhere. Plant the cloves, *i.e.*, the separated portions of the "bulbs," in shallow drills about a foot asunder, and 6 inches apart in the row, covering them with soil to the depth of an inch or two. Or plant whole bulbs a foot apart each way, and never deep, as wet is apt to get down among the cloves, causing canker and mildew. Merely stretch a line or measure; take the bulbs by the neck and press them half or say two-thirds into the soil. Then drop a pinch of fine sifted cinder ashes over them, to prevent worms from drawing them out of the ground. February is about the best season to plant them. A small quantity may be planted in autumn, if it is desired to have a stock early the following season. From this autumnal or, to speak more precisely, October planting, bulbs may be taken up for use early in the succeeding summer. Any time after the leaves turn yellow the crop may be taken up and dried, hanging it up in bunches by the stalks in any airy room. It requires no culture whatever, excepting to be kept free from weeds—if it be necessary to mention in connection with any one small crop what is a first necessity with all. In England Garlic is but little used in comparison with its immense consumption on the Continent.

JAS. BARNES.

### POTATO CULTURE IN JERSEY.

LET us first consider how the cultivation is carried on, and afterwards cursorily examine its effects. The selection of suitable land is the first consideration. If the soil be what is termed of a warm nature, and with a gentle declivity southwards, so much the better. The next important point is the preparation of the soil; we do not now find it necessary to cultivate so deeply as was formerly the practice. When the ground has been ploughed and well harrowed, it is the general custom to spread well-made stable-manure on the surface, at the rate of ten tons per vergée\*; no sea-weed is used, but a much more powerful agent has taken its place, namely, guano. The Potato rows are now closer than formerly; the planting takes place on large pieces, in the manner before explained, with the use of a small plough for making and covering the drills. As will be noticed, the manure in this manner is ploughed in with the sets; then, in addition to this, guano is used, very frequently at the rate of 200, or even 300 lbs. per vergée. Those unacquainted with the growth of early Potatoes will be amazed at this apparent extravagance of fertilising power; but extravagance it is not, as will be by-and-by perceived. The preparation of the plant intended for sets is of the utmost importance. Kidney Potatoes as a rule are planted whole, and the round varieties are planted in strong sets, with eyes from the crown of the plant. The Kidney varieties commonly planted are the Ashleaf, the Prolific, and the Winford, *alias* Early Fluke. The round varieties most esteemed are the Cherbourg *Trois Mois*, the Dalmahoy, and the Early Regents. Potatoes intended for planting should be dug before the haulm is entirely dried up; when dug they should be allowed to harden by exposure to the air and sun, occasionally turning them. Then at the fall of the year, if they are stowed away singly in layers on wooden floors it will retard too early a vegetation, which otherwise is frequently the case. By a little attention the tuber in this way is checked in its habit of early growth, and when the moment arrives for planting, it can, if required, be forced; but it is not often that any forcing is required, the eyes will break out into vigorous shoots, and when they are fully developed, say about half an inch in length, the tubers may be planted, taking care to place the shoots uppermost. In this manner one month at least may be gained in bringing the Potato out of ground. The preparation of the sets must be viewed as of primary importance, taking care always to select plants of good and early habit; this, together with a suitable and well-manured piece of ground, forms in fact the only secret in the culture of the early Potato.

The planting commences in January, and is usually all finished by the end of the next month. The next operation is the forking-up, or loosening of the ground between the rows; this is performed when the plants are fairly out of ground, either with the prong, the crook, or with a small implement in the form of a horse-hoe, usually drawn by two men. The soil being thus well opened, if not checked by

frosts, which unfortunately is sometimes the case, the plants will grow quickly, so that by the middle of April they are all hoed up. In the early sheltered places some are much more forward, while in the later ground others are less so. The first lot of any importance is usually sent up to the London markets about the end of April. As time advances the business rapidly increases, so that, by the end of May or the commencement of June, in ordinary years, great activity prevails in connection with this trade. There is no season throughout the year in which the farmer is so busy as during the sale of his early Potatoes. A day is frequently of the greatest importance in the market value of the goods; and, therefore, no sooner do they approach maturity than all hands are fork in hand at the work. Many consign their produce to salesmen in London; the goods are packed in baskets or barrels, and forwarded by the steam-vessels which daily ply between this island and the English ports, and thence on by railway to their destination. Others sell to the merchants here, who also export in the same manner, but on a larger scale. These, with the rest of the community, have the advantage, by means of telegraphic communication, of knowing hourly, if necessary, the state of the London markets.

So much said respecting the time, the mode of culture, and the sale of the Potato; let us look back at the fields whence the Potatoes have been dug, and see what is there being done. Another crop is being sown to follow. It may be, if on a piece of ground which was cleared off early, that a late crop of Potatoes is being set; this certainly is only the exception—the rule is to have a succeeding crop of either Swedes, Mangolds, or Turnips; we have also seen Barley sown, but rarely with advantage. It will now be understood that the heavy dressing of manure used for the Potato is again to be called upon to supply nourishment to the succeeding crops, and what splendid produce of roots do we often see! During our experience in these matters we have invariably noticed that some of the heaviest and best returns of roots have been in immediate succession to early Potatoes.

In our remarks on the manure employed we have mentioned guano. We would observe that this article, so valuable to the farmer, was first brought to this island from Ichnaboe in 1811, when its worth was much questioned and its use very little known; it is, indeed, comparatively only of late years that it has been extensively employed. Its effects are surprising: we have seen on the same piece of ground two plots, one dressed with good farm-yard manure, the other dressed and treated precisely in the same manner, but with the addition of guano at the rate of 300 lbs. per vergée, and the two planted with Fluke Potatoes, when a difference of more than 50 per cent. resulted in favour of the piece where guano had been applied. We have also observed that, where the Potatoes were allowed to remain long in the ground, the haulm on the plot where the guano had been applied continued longer to vegetate than on the other; and, finally, the haulm dried up somewhat in the manner before described. In 1867 there were imported to this island 379 tons of guano, and in 1868 the quantity amounted to 196 tons. It will be seen by this how much guano is now valued; and, as its particular employment is for the culture of the Potato, some approximate idea can be made of the quantity used for the crop. At the same time we must guard against drawing definite conclusions hastily on this point, as we know that guano is coming greatly into favour, and is used by many for Grass land in lieu of sea-weed; and, in a general way, if the farm-yard cannot produce a sufficient supply of manure to meet the farmer's wants, he has frequently recourse to guano to make up the deficiency.

By reference to the returns made here last year for the information of the Board of Trade, we learn that Potatoes occupied 5,129½ vergées of our land; and, as the whole superficial area of the island is calculated at 61,613 vergées, it follows that nearly one-twelfth part of the island's surface was devoted to the crop. Let us next see what has been the quantity of the produce exported from the island, and endeavour to compute what is the gross amount returned to the growers of Potatoes by the export of the year 1868. From the collective statements kindly placed at our disposal by the Custom-house authorities, the agents of the steam-packet companies, and merchants, we find the exports to have been as follows:—In packages, by steam-vessels to Southampton, Weymouth, and Littlehampton, 5,158½ tons. The first package left the island on the 19th of March; this was followed by another on the 24th, by four more on the 26th, by two on the 7th of April, by forty-three on the 21st of April, when the season may be said to have opened. On the 30th of the month the number swelled up to 143 packages. In loose cargoes by sailing vessels there were shipped for the following ports:—Plymouth, 31 tons; Newport, 276½; Southampton, 100½; London, 469½; Cardiff, 505; Lymington, 10; Swansea, 917½; Liverpool, 2½; Caernarvon, 6; Gloucester, 32; Sereq, 1; Barbadoes, 80; total, 2,431½ tons; thus giving a total of 7,890 tons, the value of which we deduce from statements of returns to have been as follow:—

\* 4½ vergées are equal to an English acre.

Produce shipped in packages, £44,331; Produce shipped in loose cargoes, £11,112; total, £55,573.

In taking into consideration the produce of the land on which the early Potatoes have been cultivated, we must not omit to add to the amount exported (which shows a gross return of more than 17s. 6l. per vergée on the whole area of the island for the export of Potatoes only), the quantity left in the island for the supply of nearly 60,000 inhabitants, and also the plant for the ensuing year. These two items must be very considerable. Moreover, we must add to the produce of the same ground the successive root-crops to which we have alluded, which enable the farmers to keep more of their holdings in Grass, and consequently to increase the number of their stock. Furthermore, let us not lose sight of the wonderful activity prevailing in these parts during the Potato season. Commerce, the twin sister of agriculture, is not without its share of benefit. Steam communication is doubled, and its advantages are extended to passenger as well as to cargo traffic. In a word, the whole machinery of business is at work, and its good effects conspicuously felt through every channel of the insular trade.

We close this report with the following tabular statement of exports, taken from published returns, of several preceding years, commencing with 1807, when Potatoes were first exported:—

Years	Tons.	Years.	Tons.	Years.	Tons.
1807	600	1835	1396	1854	4330
1808	1497	1836	3701	1855	4197
1809	849	1837	10,351	1856	7236½
1810	1362½	1838	12,032	1857	4960
1811	14,00½	1839	14,941	1858	3093
1823	3680	1840	17,348	1859	2211
1824	5747½	1842	18,560	1860	2677
1825	5836	1845	3822	1861	2969
1826	2558½	1846	5461	1862	2893
1828	8364	1847	6428	1863	3908
1829	3963	1848	5390	1864	6795
1830	9289	1849	4992	1865	3216
1831	2985	1851	5662	1866	1680
1832	5495	1852	3354	1867	6251
1833	1859	1853	3776		

—C. P. Le Cornu, R. Agr. Soc. Proceedings.

## THE PROPAGATOR.

### PROPAGATION OF THE IPEACACUAN PLANT.

(CEPHAËLIS IPEACACUANHA.)

THIS plant (says Dr. Balfour, in "Transactions of the Royal Society of Edinburgh") has been cultivated in the Edinburgh Botanic Garden for upwards of forty years, but it was not propagated to any extent until 1870, when a proposal was made to attempt the cultivation of the plant in India. This suggestion was made on account of

Roots of the Ipeacacuanha plant.

the continued destruction of the plant by the collectors in Brazil, and the risk of scarcity in the supply of this most valuable remedy for dysentery. The Secretary of State for India, under the recommendation of several medical officers in Bengal, authorised an attempt to propagate the plant in our Indian possessions, and with that view application was made to me and others to aid in this important undertaking. Accordingly, I at once set about the propagation of the plant in the Edinburgh Garden, with the assistance of Mr. McNab. He found that the plant could be multiplied very rapidly by dividing the annulated root, cuttings of which, though

very small, give off young shoots when placed in favourable circumstances. By this means, numerous plants were produced very rapidly, and the method was also followed by the Messrs. Lawson, who supplied a large stock of vigorous plants.

It appears from a report by Dr. King, director of the Calcutta Botanical Garden, that in 1866 a single plant of Ipeacacuan was received at the Calcutta Garden from Dr. Hooker, but apparently artificial propagation had been attended with sparing success, as Dr. King reported at the beginning of 1872 that "the only surviving offspring of the Kew plant amounted to five plants in Sikkim, and seven in the Calcutta Garden." It is understood that cuttings of

Annulated root and leaf-bud of Ipeacacuanha.

the stem were planted, but not of the roots. When, however, the plan proposed by Mr. McNab was adopted for the propagation of the plant, much greater success was obtained. In May 1871, a Wardian case was sent from the Edinburgh Botanic Garden containing twelve plants, and in October seventy-four plants were despatched. The greater number of these reached their destination in a good state. Since then 112 plants were sent in July, and sixty-eight in November, 1872, making in all during 1871-72, 300 plants.

The original plant in the Botanic Garden had produced flowers on several occasions, but no fruit or seeds. The cuttings taken from its roots grew rapidly, and at the end of a year's growth many of them flowered, producing shrubby stems. Some of the plants assumed a branching habit, and attained a large size. The dimensions of the largest specimen in the garden are as follows:—Height, 16 inches; length of leaves, 6½ inches; breadth of leaves, 3¼ inches; length of peduncle, 1 inch; circumference of stem, three-quarters of an inch.

The following are the general characters of the plant cultivated in the garden:—Stem more or less shrubby when fully grown, simple or branching, with marks of the leaves giving a somewhat annulated aspect, varying in height from 12 to 16 inches. The young stem is herbaceous and quadrangular. The root is about the size of a writing-quill. It is well characterised by its irregularly contorted

Annulated root slightly enlarged.

and annulated appearance. The roots spring from the lower part of the shrubby stem, and may be said to combine the usual functions of the root with those of the stem, inasmuch as they are capable of producing leaf-buds; when the root is cut into pieces, each portion produces a leaf-bud. A very small portion of root, not larger than one-eighth of an inch, is sufficient for the purpose of propagation. The outer or cortical part of the root is cellular, and has small projecting rings closely applied to each other. There is now a good stock of plants in India. Mr. Andrew T. Jaffray, in a letter to Sir Robert Christison, dated Darjeeling, 19th of September, 1872, states that by the end of the year he expects to be able to report that he has from 2,000 to 3,000 plants of Ipeacacuan in cultivation.

**Forests and Rainfall: A New Theory.**—Experiments made by Von Pettenkofer on the amount of water evaporated from an Oak tree, show that atmospheric humidity, in so far as it depends upon the presence of forests, is promoted rather by the roots of trees drawing moisture from the earth, than by any attraction exercised on rain clouds by the leaves. The latter serve rather as outlets through which the moisture drawn from the soil passes into the air. The Oak tree observed by Pettenkofer was estimated to have 751,592 leaves, and the total amount of evaporation in a year was computed to be 8½ times more than that of the rainfall on an area equal to that covered by the tree, the moisture exhaled by the leaves being equal to 211½ inches, while that from rainfall was but 25½ inches.

## WORK FOR THE WEEK.

## PRIVATE GARDENS.

**Flower Garden.**—Presuming that all the hardier bedding plants, such as Pelargoniums, Echeverias, Lobelias, &c., are planted, the more tender sorts, such as Alternantheras, Coleuses, &c., should now be put out, provided the situation is sheltered. Maintain neatness in the flower garden and pleasure grounds by means of frequent mowings, sweepings, rakings, and rollings. Thin out superfluous shoots of the finer kinds of shrubs, so as to invigorate the others, and from the trunks of trees remove sprayey shoots; also suckers from the roots. Apply a few neat stakes to tall-growing herbaceous plants, such as Pyrethrums, Phloxes, Pentstemons, &c., and likewise strong stakes to Hollyhocks and Dahlias. Tie up rampant shoots of Roses and give all choice kinds a syringe forcibly with the garden engine, to divest them of aphid, and if these or other insects are present in any great quantities diluted tobacco water should be used a night or two after the application of clean water. Propagate Pansies, Alyssums, Aubrietias, Wallflowers, and other plants from cuttings, under handlights, at the base of walls or in other sheltered places.

**Greenhouse Soft-wooded Plants.**—Keep up a succession of annuals, such as Balsams, Cockscombs, Selizanthuses, Brachycome, dwarf Asters, Mignonette, and others. For starting these, a little bottom heat is beneficial, and during all stages of their growth plenty of ventilation must be admitted, and abundance of water given. Thin the scarlet *Salvia fulgens* and the blue *S. patens*, few plants are more beautiful, free blooming, and satisfactory, either in pots or planted out; they require rich soil and plenty of water, and by cutting off the spent flower-spikes and maintaining a regular supply of young wood they continue in excellent flowering condition until late in the season. Keep Pelargoniums and shrubby Calceolarias in open houses or frames, and give them plenty of water, but as soon as they come nicely into bloom remove them to the conservatory. Discard herbaceous Calceolarias when past their best, and if seed be required let it be saved from plants that have borne the finest formed and best marked flowers; place them in a cool and light house, and supply them moderately with water. Any suckers of Cinerarias ready for potting should now be removed from the old stock, potted singly in moderately rich soil in thumb or 60-sized pots, and put for a time in cold frames, placed so as to face the north. Repot Tree Carnations as they require it, and keep them in gentle heat, to bring them well into flower. Keep up a good stock of single and double-flowered zonal Pelargoniums. Mulch Japanese Lilies in pots with decayed manure and turfy loam in equal parts, and introduce a few now and then to warmer quarters, to bring them into flower in succession. Shift Chrysanthemums into their flowering pots, and keep them in cold frames, or plunged out of doors.

**Window Plants and Boxes.**—Windows should now be gay with flowering plants, both inside and out. Such plants as are inside should be as near the glass as possible, regularly and well watered, but they should not be permitted to stand in pans or saucers of water for any length of time; their young growths should be pinched if they become too long. Myrtles, Camellias, India-rubber plants, Callas, and similar plants that have smooth and thick leaves should be gently sponged; but Pelargoniums, Heliotropes, most kinds of Ferns, and such plants as have hairy leaves, should be taken out of doors and sponged occasionally, in order to clear them from dust. Window boxes, if well drained, allow superfluous water to pass off freely; water may, therefore, be administered plentifully, without any fear of its stagnating about the roots. A good loamy soil, mixed with leaf-mould or decayed manure makes a good compost for plants in boxes. The beauty of Calceolarias is soon over, as is also that of several other flowers; therefore, some preparatory means must be adopted for supplying their places with fresh material, and for this purpose Pelargoniums, small plants of *Acacia lophantha*, Fuchsias, Nasturtiums, Lobelias, Mignonette, &c., should be held in readiness. Plants now in the boxes should be induced to display themselves to the best advantage, and for this purpose if a very narrow strip of wire netting be run along the top of the box and made to lean backwards, and another piece bent downwards in front, and some of the shoots of the plants attached thereto, a large and showy surface is obtained. Brackets and suspended baskets should likewise be well furnished with suitable plants, such as the hardier sorts of Adiantums, Polypodiums, Aspleniums, Aspidiums, Athyriums, Pterises, &c. Ivy-leaved Pelargoniums, Lobelias, Petunias, and the small-leaved dwarf-growing Ivies are also very pretty when used as basket plants.

**Stove Plants.**—These, as a rule, are now making free growth, and, consequently, should be kept moderately warm, shaded, and well watered. By running Dipladenias, Stephanotis, Clerodendrons, and Allamandas, on threads stretched across the rafters inside the houses, a greater quantity of bloom is produced on them than when their growth is more restricted. If required for specimen plants the strings may be cut down and drawn out from amongst the

shoots, which should be carefully and equally trained around a trellis. Repot all young plants as they require it, and by plunging them for a few days afterwards in a gentle bottom heat the roots are stimulated into action. Attend to staking, tying, and keeping the plants free from insects. Ventilate moderately in the earlier part of the day, and sparingly in the afternoon; shade from strong sunshine, and with syringings and water sprinkled on the walls and paths keep up a moist atmosphere.

**Orchids.**—Steady heat, plenty of root and atmospheric moisture, but little ventilation, except during fine sunny weather, and shade are now necessary. Plants in bloom should be all placed by themselves if possible, so as to preserve their blossoms getting spoiled with water from the syringe, or they may be mixed with other flowering plants in the warmer portions of the conservatory or other plant-houses. If so transferred, after they have done blooming, bring them back to a cool shady part of the stove or Orchid house. Many Orchids, when in flower, last in beauty for weeks in a sitting-room, provided it is neither dusty nor subject to draughts; and, amongst these, Lycastes stand in the first rank, as do also *Dendrobium nobile*, *Saccolabium guttatum*, *Odontoglossum Alexandrie*, and other kinds.

**Ferns.**—These are now growing vigorously, therefore abundance of root and atmospheric moisture is necessary as well as gentle syringings. Cheilanthes, Gymnogrammas and other farinose Ferns, as well as Adiantums, should not be syringed overhead, such treatment being more injurious than beneficial to them. Sow spores under favourable circumstances, prick them off in little patches about half an inch or more apart after they appear, and pot all seedlings requiring it, as well as young and vigorous growing Ferns of all kinds. Thin out any old and decaying fronds so as not to impede the progress of younger ones. Replenish Fern baskets; seedlings inserted between the meshes of wire baskets give a good appearance to all suspended plant baskets.

**Indoor Fruit Garden.**—For Pines maintain a strong, moist, and steady heat; avoid draughts, and give just sufficient air to prevent too great a rise of temperature. Remove all strong suckers, pot, and start them in bottom heat. Gradually lessen moisture, both in the air and soil, where Pines are ripening fruits. Notwithstanding many instances of badly ripened Vines last year, through careful treatment, and slow and not too early forcing, the plants are bearing well this season. Thin the shoots and berries as required; only allow one bunch to each lateral, and pinch the shoot at the second eye beyond the bunch. If the borders are indoors see that they are thoroughly moistened. In the Peach house border watering must also be attended to, and liquid manure supplied now and then. Disbudding, syringing, and other daily operations will require attention. Top dress Cucumber beds, immediately the young roots are seen to be protruding above the surface, thin out superfluous laterals and decaying leaves, and always maintain a regular supply of young and good bearing wood. Never permit too many fruits to be on one plant at a time, as they only prevent each other's development. Syringe both Melons and Cucumbers twice a day with clean tepid water; but if mildew be suspected, mix with it a little flowers of sulphur. Strong and healthy plants militate against red spider; therefore manure water must be freely applied to Cucumbers. Melons ripening require to be kept a little on the side of dryness. Successions of Strawberries must be kept up by introducing from a cooler house to a warmer one, such plants as are bearing fruit. Prepare pots for runners for next year's plants, and plant out, on a warm piece of ground, plants that have lately been forced, giving them at the same time a good watering. In Pine stoves, or other forcing houses, near the glass have a successional supply of French Beans: they require plenty of water, as well as liquid manure, also syringing twice a day, and the minute red spider is discerned, let the plants affected by it be immediately discarded. Give plenty of air to Potatoes in frames, and water them moderately. Celery and Tomatoes in frames should be freely exposed, and planted out when convenient. Vegetable Marrows and Gherkins should be planted out before their roots become matted in the pots.

**Hardy Fruit Garden.**—Though there are fair prospects of a good fruit crop as a rule, yet in some places Pears, Apricots, and Peaches are thin; bush fruits and Strawberries look well. Disbud wall trees, remove blistered leaves from Peaches and Nectarines; train in shoots intended to be retained. Destroy aphid with tobacco-water, grubs and caterpillars by means of hand picking, ants by scattering some guano along the base of the walls, and mildew on young trees with flowers of sulphur. The ends of the shoots of fruit bushes are frequently infested with aphides, for which, if not too laborious, syringe with tobacco-water, pinch off the ends so infested and burn them, or with a brush like a painter's and a mixture of tobacco-water, soft soap, and a little of Gishurst's compound, rub off, and destroy the depredators. Gooseberry bushes should be well clothed with foliage, which is of material advantage in protecting the fruit from the sun.

## SOCIETIES, EXHIBITIONS, &amp;c.

## ROYAL HORTICULTURAL SOCIETY.

JUNE 4TH &amp; 5TH.

THIS was one of the large summer shows, and was held under a tent on the terraced garden. Its chief features were stove and greenhouse plants, Orchids, Ferns, and new plants.

**Stove and Greenhouse Plants.**—In the class of nine stove and greenhouse plants, Mr. Baines was first, with a very fine group of nicely grown plants, among which were *Azalea indica* Mars, *Phonocoma prolifera*, *Boronia pinnata*, *Ixora coccinea*, *Dracophyllum gracile*, *Hedera tulipifera*, *Aphelexis macrantha purpurea*, *Erica coccinea minor*, and *E. Cavendishii*. Mr. Ward was second. In the class of six stove and greenhouse plants, Mr. Baines was again first, with an admirable group; Mr. J. Wheeler, Stamford Hill, was second, and Mr. G. Wheeler, Regent's Park, third. In the nurserymen's class of six plants, Messrs. Jackson were first, with large and densely flowered plants of *Erica depressa*, *Aphelexis macrantha purpurea*, *Azalea variegata*, *Anthurium Scherzerianum*, and *Dracophyllum gracile*; Mr. E. Morse was second. In the class of twelve plants, Mr. Ward was first, with a dozen well-grown medium-sized plants, one of which—*Kalosanthes Frederick Desbois*—was extremely brilliant.

**Orchids.**—These were particularly good. In the amateurs' class Mr. J. Ward was first, with good plants of *Anguloa Clowesii*, *Cypripedium Stonei* and *villosum*, *Oncidium sarcodes*, *Phalenopsis grandiflora*, *Cattleya Mossie*, and some varieties of *Odontoglossum Alexandre*. Mr. F. Rutland, Goodwood, was second, with finely flowered plants of *Cattleya Mossie*, one of which had twelve flower spikes; *Dendrobium densiflorum*, with ten fine flower spikes; *Cypripedium candidum*, and others. Mr. W. Cuthbert, Chase Park, Enfield, was third. In the amateurs' class for six, Mr. Hill, the Poles, Ware, was first, with half a dozen fine plants; Mr. Douglas, Loxford Hall, was second; Mr. Ward, third; and Mr. Cuthbert, fourth. In the nurserymen's class Mr. B. S. Williams was first, with a collection of wonderfully fine plants, consisting of *Sticcolabium retusum*, *Cattleya Mossie* and *lobata*, *Cypripedium candidum*, and *barbatum superbum*, *Lælia purpurata* with six flower-spikes, and others. Mr. Wm. Bull was second, with *Cattleya Warneri* and *Mendeli*, *Lælia grandis*, *Eriopsis rufidobulbon*, &c. Messrs. Jackson were third. In the class of six Orchids Mr. Bull was first, with the pretty *Lælia majalis* and *L. purpurata*; *Cattleya Mendeli*, *Vanda suavis* and *Batemanii*, and a good variety of *Cypripedium barbatum*. Mr. E. Morse was second. Amongst others he had a well-flowered example of *Aërides Lobbia*, *Brassia verrucosa*, and *Stanhopea tigrina*. Mr. Denning, Loudesborough House, Norbiton, furnished a grand group of Orchids, in which were *Masdevallia ignea*, *coccinea*, *Lindeni*, *Veitchii*, *Harryana*, and *Denisonii*, all brilliantly in flower; a plant of *Odontoglossum vexillarium* in bloom; *Dendrochilum filiforme*, laden with drooping clusters of yellowish flowers; and several fine varieties of *Cattleyas*, *Aërides*, *Vandas*, &c. Messrs. Veitch and Sons showed a superb example of *Odontoglossum vexillarium* with two flower-spikes, each having half a dozen expanded flowers on it; likewise many other fine and especially new sorts of Orchids intermixed with their miscellaneous collections of plants.

**Ferns.**—Of these some very fine examples were shown, but none equal to half a dozen shown in the amateurs' class by Mr. Baines. These were immense specimens, fresh, and in fine condition; they consisted of *Gleichenia rupestris* and *Spelunca*, both nearly six feet through, *Cibotium princeps*, with very large and spreading fronds, *Dicksonia antarctica*, *Cyathea dealbata*, and a fine tubful of *Davallia bullata*. Mr. Cole was second; amongst others he had a very fine plant of *Asplenium Nidus Avis*; Mr. T. M. Shuttleworth was third. Messrs. Jackson and Mr. Aldous, Gloucester-road, were amongst the successful contributors in the nurserymen's class. Collections of hardy Ferns consisted chiefly of *Athyrium Filix-Mas* and *A. F. Fœnna* and their varieties, *Scelopendrium*, *Polypodiums*, &c.; they were exhibited by Messrs. Jackson, Mr. Morse, Mr. James, and others. R. A. Thompson, Esq., South Kensington Museum, contributed a dozen varieties of *Polystichum angulare* found wild in Devonshire.

**Palms and Dracænas.**—Some beautiful Palms were contributed, especially amongst the miscellaneous collections. Mr. J. W. Wimsett was first in the nurserymen's class, with medium-sized plants of *Verschoffia melanochæta*, *Areca Baueri*, *lutescens*, and *Verschoffia*; *Phœnicophorium Seychellarum*, and *Astrocarum mexicanum*; Mr. Aldous was second. In the amateurs' class, the first prize was awarded to Mr. Cole, who exhibited an excellent group, in which were *Chamærops humilis*, *Rhapis flabelliformis*, *Latania borbonica*, *Scaforthia elegans*, *Areca lutescens* and *rubra*; Mr. Hill was second, and Mr. G. Wheeler third. For a pair of *Dracænas* Mr. Bull was first, with two handsome specimens of the green-leaved *D. lineata*.

**Succulents.**—For Mr. Peacock's prize for 50 plants of these, only two collections were staged. The first prize group came from Mons. Pfersdorff, Paris, and consisted chiefly of *Cereuses*, *Gasterias*, *Echinocacti*, &c., many of them being great curiosities, from the way in which they were grafted. Mr. Ware was second with a collection of *Sempervivums*, *Opuntias*, and similar plants.

**Roses.**—In the class of six Roses in pots Mr. C. Turner, Slough, was first with fine plants, well furnished with large and fresh flowers; the kinds were *Madame A. Duneau*, *Charles Lawson*, *Madlle. Margottin*, *Vicomte Vigier*, *Victor Verdier*, and *Juno*. Messrs. Paul

and Son were second with an excellent half-dozen Roses. For 45 trusses of cut blooms of Roses Mr. Turner was first, and Messrs. Paul and Son second, the blooms in both cases being remarkably fresh and fine. From Messrs. Mitchell and Sons, Maresfield, came two boxes of cut flowers of *Maréchal Niel*, all large and very fine blooms.

**New Plants.**—In the class of six, introduced by the exhibitor, and not yet in commerce, Messrs. Veitch were first, with *Dipladenia insignis*, *Aralia elegantissima*, *Dracæna Baptistii*, *D. amabilis*, *Adiantum speciosum*, and *Tillandsia Zabuii*. Mr. Bull was second, with *Pritchardia grandis*, *Croton majesticum*, *Dracæna Goldieana*, *Encyphalartos Jamesoni*, *Cycas imperialis*, and *Cyathea Burkei*. For three new plants, introduced by the exhibitor in 1872-3, Messrs. Veitch were again first, with *Odontoglossum vexillarium*, *Aralia Veitchii*, and a *Croton*. Prizes were offered by Mr. Wm. Bull for twelve new plants introduced and sent out for the first time since the commencement of 1870. In the nurserymen's class for these, Mr. J. W. Wimsett was first with *Maranta Makoyana*, *Kentia Canterburyana*, *Dænonorops palembaniensis*, *Dracæna splendens*, *D. Shepherdii*, *D. metallica*, *Pandanus Veitchii*, *P. decornis*, *Macrozamia corallipes*, *Cureuligo recurvata striata*, *Dieffenbachia nobilis*, and *Guibelmia utilis*. Messrs. E. G. Henderson were second, with (in addition to some of the above) *Nidularium spectabile*, *Dracæna concinna*, *D. Fraseri*, *D. pulchella*, *Maranta Seemannii*, *Pandanus Lais*, and *Aralia Guilfoylei*. Messrs. Downie, Laird, and Laing were third, with (in addition to some already named) *Dracæna illustrata* and *Alcasia Marshallii*. In the amateurs' class for a dozen plants shown under the same circumstances, T. M. Shuttleworth, Esq., Harley-street, Cavendish-square, was first, with *Prinula japonica* and *Macrozamia spiralis orburea*; Mr. Croucher, gardener to T. Peacock, Esq., was second, with *Pandanus ceramensis*, *Dracæna ornata*, *Cypripedium ævium*, and *Stadmannia amabilis*; Mr. W. Carmichael, Crown Hall, Bath, was third, with *Phyllanthus nivosus*, *Croton fucatum*, and *Alcasia illustris*.

**Cut Flowers.**—For eighteen bunches of these, Miss M. A. Baines was first, with remarkably fine trusses cut from tender plants, consisting of *Bougainvillea glabra*, *Staphanotis floribunda*, *Phajus Wallichii*, *Sobralia macrantha*, *Bouvardia jasminoides*, and several kinds of *Ixoras*, *Allamandas*, and *Dipladenias*. Mr. Cuthbert was second; and Mr. E. Rowe, the Rookery, Roehampton, third. Mr. George, Putney Heath, was first for a collection of double-flowered Peonies; and Mr. Ware second for Peonies and first for double Pyrethrums; in addition to which he showed a stand of fancy Pansies, and one of the very dark self-coloured one, called *Pluto*. Messrs. Hooper and Co., Covent Garden, exhibited a wonderfully fine collection of blooms of *Ixia*, *Tritomas*, and other bulbous plants. Messrs. Veitch and Sons had a superb collection of *Rhododendron* and *Azalea* blooms; also a stand of blooms of other hardy shrubs, including a branch of the *Fremontia californica*, very thickly furnished with flowers; a branch of *Viburnum platanum*, laden with masses of pure white Hydrangea-like clusters of flowers; and blooms of many other sorts of hardy plants. Mr. Rowe also showed a stand of *Rhododendron* blooms.

**Miscellaneous Subjects.**—From Mr. Wm. Bull came a grand collection of new plants; and Messrs. Veitch and Mr. B. S. Williams likewise contributed similar collections. Mr. Bull also showed a fine group of Cycads, and Messrs. Veitch and Sons a specimen of *Lilium giganteum* in bloom, and a group of standard *Rhododendrons*. Messrs. Noble, Bagshot, sent a group of *Clematises* and *Spiræa japonica*, and Mr. Cuthbert, of Barnet, a basketful of *Weigela hortensis nivea*, a free flowering white flowered kind. Messrs. Standish and Co., Ascot, contributed a group of beautifully coloured Japanese Maples, several fine plants of the handsome white flowered *Abutilon Boule de Nieve*, and a specimen of *Passiflora vitifolia*, with pretty red flowers. Messrs. Aldous and Co. furnished a good group of miscellaneous plants, and Messrs. E. G. Henderson & Son a group of *Pelargoniums*, *Petunias*, very fine *Mimuluses*, excellent varieties of *Anthurium Scherzerianum*, &c. Mr. Wm. Paul, Waltham Cross, furnished a fine collection of tri-color *Pelargoniums* and cut flowers of zonals. Mr. T. Pestridge, Uxbridge, likewise showed a group of fine tri-color *Pelargoniums*. Of *Cycas revoluta*, a specimen in flower, 8 feet in diameter, and bearing some seven dozen fine leaves, was exhibited by Mr. S. Woodford, Eastwell Park, Ashford, Kent. Several tastefully arranged vases furnished with flowers were exhibited, also an example of dinner-table decoration tastefully set off with artificial flowers. This was exhibited by Messrs. Adecock & Co.

**Fruit and Vegetables.**—Fruit was for the most part excellent in quality, but very few vegetables were shown. For three Queen Pine-apples Mr. Hepper, the Elms, Acton, was second, the first prize being withheld; for a prickly Cayenne, Mr. Rutland was first with a fine fruit, Mr. Hepper being second. Grapes were remarkably fine; for a basketful not less than 12lbs. in weight, Mr. T. Bannerman, Blythfield, Rugby, was first, with fine bunches of Black Hamburgh, and Mr. Bones, Havering Park, was second. For a dish of Black Hamburgh Grapes Mr. Bannerman was first with three finely set bunches,—the size, colour, and plumpness of the berries being all that could be desired; Mr. Douglas was second, and Mr. J. Craven, Barnet, third. For a dish of any other sort of Black Grape, Mr. Bannerman was first, with very fine examples of Black Prince. For Frontignans or any round Grape having a Muscat flavour Mr. Bannerman was first, with Grizzly Frontignan, and Mr. D. Pizzey, Fulmer, Slough, second, with white Frontignan. For a dish of Buckland Sweetwater Mr. Douglas was first, with well-ripened bunches; and Mr. A. Reid, Possingworth, was second. For any other white Grape Mr. T. Mills showed Foster's White Seedling, and Mr. Pizzey the White Muscadine. For a dish of Peaches Mr. Sage, Ashridge Park, was first with fine fruits of Violet Hative; Mr. W. Hill, Hale Hall, Stafford, was

second with Royal George; and Mr. Bannerman third, with the same sort. For a dish of Nectarines Mr. W. Gardiner, Lower Ealington Park, was first with Violet Hativie; Mr. Miles second with Elruge; and Mr. Hill third. For a dish of Figs Mr. Sage was first with Brown Turkey; Mr. Miles, second with Brown Ischia; and Mr. H. Stapleton, Spring Grove House, Isleworth, third with Lee's Perpetual. Mr. Miles was the only exhibitor of Cherries; he showed a dish of very fine Black Circassian, and the same of Bigarreau, for both of which he had a first prize. For pale red and Pine flavoured Strawberries, Mr. Douglas was first with British Queen, Mr. Bones second with the same, and Mr. Stapleton third with Sir C. Napier. For dark red kinds, not Pine flavoured, Mr. Douglas was first with Premier, and Mr. Chard second. For a green or pale fleshed Melon, Mr. Miles was first with Hybrid Cashmere. Messrs. Gardiner, Earley, Cox, and Hall, showed respectively some good examples of late keeping Apples, and Mr. Reid a dish of Cape Gooseberries; Mr. Bennett, Hatfield, showed a dish of very fine Dr. Hogg Strawberries, and also some good Cucumbers. Messrs. Watts and Sons contributed some fine examples of their Northampton Hero Broccoli, which the Committee considered to be identical with the Leamington Broccoli, and which is one of the very best of Broccolis. Messrs. E. Francis and Co., Hertford, showed examples of Hill's June Broccoli, which was considered to be the same as an old variety of no great repute. Prizes were offered by Messrs. Carter and Co. for six dishes of Peas, to include Maclean's Blue Peter, Carter's White Gem, and Carter's First Crop Blue. For these Mr. G. Brown, Hawley Court, Henley-on-Thames, was the only exhibitor; and, as his Peas were exceptionally fine, they received the first award.

**First-class Certificates.**—These were awarded to the following:—

*Dracena Baptistii* (Veitch), a strong-growing sort, with copper-coloured leaves, edged and flaked with red, the young leaves being green, changing to copper colour with age.

*Aralia elegantissima* (Veitch), an extremely handsome sort in the way of Veitchii, but stronger growing; the leaflets, instead of being undulated, are deeply indented.

*Tillandsia Zahnii* (Veitch), a showy Bromeliad, the leaves being flamed with bright red, and the flower-spike yellow.

*Dieffenbachia Braziliensis* (Veitch), a showy plant, with habit somewhat like Bausei, and the ground colour a deep green flamed with yellow, in which small white spots are multitudinously scattered.

*Veronica diosmaefolia* (Veitch), a pretty dwarf, hard-wooded, greenhouse plant, with leaves like those of the Diosmas, each shoot bearing freely pretty heads of pale lavender flowers.

*Anthurium crystallinum* (Veitch), an exceedingly pretty-leaved kind in the way of grande, of a deep green colour, the larger veins being conspicuously marked like silver.

*Phycella pulchra* (Veitch), a pretty little Liliaceous plant, with red trumpet-shaped flowers that are greenish yellow at the neck.

*Laelia Wolstenholmie* (Veitch), a pretty Orchid, the flowers of which are of a whitish colour much suffused with violet, particularly the lip.

*Croton spirale* (Bull), a true spiral-leaved sort, very remarkable and ornamental.

*Croton cornigerum* (Bull); the leaves of this are somewhat like those of Weismannii in colour, shorter and broader in form, and curved like a horn.

*Croton grande* (Bull), a large, strong-growing sort, with deep green leaves, of which the midrib and principal veins are rose coloured.

*Croton majesticum* (Bull), a long-leaved graceful kind, with metallic green leaves striped and marked with yellow and rose.

*Chamocrops humilis variegata* (Bull), a variety prettily variegated with yellow.

*Bertolonia superbissima* (Bull), an extremely pretty strong-growing plant, with large and distinct rose-coloured round spots.

*Campsidium filicifolium* (Bull), a pretty dwarf climbing plant, somewhat in the way of *Paullinia Thalicrifolia*.

*Cattleya Mendellii* (Bull).

*Pritchardia grandis* (Bull), an ornamental plant with broad undivided bright green leaves.

*Dracena rosea* (Bull), a strong-growing sort, with metallic green coloured leaves, edged with red; the young leaves being almost pink.

*Dracena Goldiema* (Bull), one of the most singular of all *Dracenas*; its leaves are short, broad, and borne horizontally on clean footstalks; their colour is deep green, barred zebra-like with silvery green.

*Cyathca Barkei* (Bull), a fine African Tree Fern, with a trunk a foot through and  $\frac{1}{2}$  feet high, surmounted by a fine close head of well-developed fronds. A fine plant.

*Colusa Verschaffeltii splendens* (E. G. Henderson), a fine bright red variety.

*Begonia vivicans* (E. G. Henderson), a bright red, free-flowering, herbaceous sort.

*Petunia The Shah* (E. G. Henderson), a showy kind—violet, shaded with magenta, and rayed with white.

*Pelargonium* (tricolor) Miss Farren (Wm. Paul), a pretty silver tricolor.

*Pelargonium* (show) Triomphe de St. Maudé (Turner), a fine kind bearing large trusses of showy crimson flowers, apparently a good market variety.

*Pelargonium* (show) Constance (Turner), a finely-formed pale rose-coloured flower.

*Pelargonium* (show) Protector (Turner), a showy bright crimson-coloured sort, with white throat, and dark upper petals.

*Pelargonium* (show) Sunray (Turner), a showy red-coloured variety.

*Pelargonium* (show) Duchess (Turner), a finely-formed flower, not unlike *P. Protector*.

*Pelargonium* (show) Blue Boy (Turner), a distinct, large, and showy kind, with pale rosy violet lower petals and dark coloured upper ones.

*Calceolaria* (shrubby) Aurora (Dean), a good sort, with fine large trusses of bloom of a crimson colour, suffused with yellow.

*Viola* (bedding) Lothair (Dean), a promising dark violet-blue coloured *Viola*.

*Lobelia pumila grandiflora pleno pleno* (Dixon) a pretty really double form.

*Silene pendula compacta* (Cole), a dwarf-growing, compact, free-blooming variety.

*Verbena Edward Perkins* (Perkins), a kind bearing large trusses of white flowers, with a rosy purple eye.

*Orotoglossum Inseleyii leopardinum*, a dark brown coloured flower, barred with a paler hue; a fine and distinct plant.

Certificates were awarded to a few unnamed *Pelargoniums*, to which no exhibitor's name was attached.

## MANCHESTER BOTANICAL AND HORTICULTURAL SOCIETY.

THE annual Whitsuntide exhibition of this Society opened on Friday, May 30th, at the Botanic Gardens, Old Trafford, under the best auspices, as far as weather was concerned. Of fine-foliaged plants, a good group of eight was staged by J. H. Birley, Esq., Pendleton; these consisted of *Scarforthia elegans*, *Cibotium Schiedei*, *Croton angustifolium*, *Theophrasta imperialis*, *Maranta fasciata*, and *Cordylina indivisa*. In the class of six stove and greenhouse plants, the best group contained an enormous and finely-grown *Gleichenia flabellata*, *G. dicarpa*, very fine, *G. dichotoma*, *G. rupestris*, *Davallia tenuifolia*, and *Brainea insignis*. Hardy Ferns were well represented, and some nice *Adiantums* were staged in Class II. A grand group of twelve stove and greenhouse plants was staged in Class I. by Mrs. E. Cole & Sons. These consisted of *Azaleas Conqueror*, very finely flowered, *Magnificent* and *Trotteriana*, *Hedera tulipiferum*, *Aphelaxis humilis*, and *A. macrantha purpurea*, *Erica afinis*, E. Lindleyana, finely grown and flowered, *Statiche profusa*, a splendid example of *Anthurium Scherzerianum*, *Pimelea mirabilis*, and *Epacris miniata rosea*.

**Orchids.**—Of these, nearly 300 examples were staged, some of them of large size, especially some plants of *Cattleya Mossie*, of which a wonderful group was shown, not only of that kind, but also of its different varieties. The best twelve Orchids in the amateur class were contributed by Mr. Mitchell, gardener to Dr. Ainsworth, Manchester. They consisted of *Aërides Lobbia*, a fine *Phalenopsis grandiflora*, *Cypripedium barbatum superbum* with twenty-seven flowers, a magnificent example of *Laelia cinnabarina*, *Phalenopsis amabilis*, *Oncidium sphaecelatum* with eight large spikes, *Saccolabium præmorsum* (very fine), the beautiful *Laelia Stelzeriana*, *Trichopilia crispa*, *Oncidium sarcodes* with three fine spikes, *Vanda suavis*, and a splendidly-flowered *Saccolabium guttatum superbum*. Mr. Hulbersty, gardener to O. O. Wrigley, Esq., was second with a large *Phaius Wallichii*, a magnificent *Calanthe veratrifolia*, *Anguloa Clowesi*, *Cattleya Mossie* (very fine), *Dendrobium nobile*, *D. transparent*, *D. crepidatum*, *Cypripedium barbatum*, a very fine *Saccolabium ampullaceum* (considered to be one of the finest examples ever seen), *Aërides Fieldingii*, and a fine young plant of *Masdevallia Harryana*, with five brilliantly-coloured flowers and several buds. The best six Orchids were staged by Mr. Williams, gardener to Jos. Broome, Esq., Didsbury. This group consisted of *Oncidium sphaecelatum* (splendidly grown and flowered), *Vanda tricolor*, *Laelia purpurata* (very fine), *Cypripedium villosum*, *Epidendrum prismatocarpum*, and *Dendrobium nobile*. Mr. Wrigley, who was second, had a fine *Cattleya Mossie*, *Dendrobium nobile* (very fine), *Anguloa uniflora*, *Cypripedium barbatum giganteum*, *Aërides virens*, and an unnamed *Dendrobium*. The best three Orchids came from Mr. Wrigley; they consisted of *Aërides Fieldingii*, *Masdevallia Harryana*, and *Anguloa Clowesi*, with large and brilliantly-coloured flowers.

**New Plants.**—Amongst these were the new *Anthurium crystallinum*, which appears to improve each time it is seen in public; *Phyllostenium Lindenii*, a stove Aroid which is so distinct in character as to be considered by the introducer likely to prove the type of a new genus; its leaves resemble those of a *Caladium* in shape, the ground colour being bright green, whilst the mid-rib and primary veins are of a silvery whiteness. These came from Mr. B. S. Williams. Messrs. Rollisson also contributed a group, which contained a new *Echmea*, named *bracteata*, apparently very distinct in character, *Toodea intermedea*, a species of *Croton* from the South Sea Islands, and others.

**Miscellaneous Subjects.**—Among these an excellent stand of bunches of cut stove and greenhouse plants was staged by Mrs. E. Cole and Sons; Pansies, by Mr. H. Hooper, Bath; superb examples of *Marcelia Niel Rose* by Mr. J. Cooling, Bath; and *Tulips* by Mr. Samuel Barlow. The large oblong tent, which has hitherto been such a prime feature of attraction at the Whitsuntide show, was on this occasion filled with *Rhododendrons*, planted out and charmingly arranged by Mr. Anthony Waterer. It was expected that the contents of this tent would have been in full bloom by Whitsuntide, but it will be another fortnight before the plants will have put on their best floral aspect. It promises then to present a sight that will doubtless be witnessed with unmixed delight by the inhabitants of Manchester.

## COVENT GARDEN MARKET.

JUNE 6TH.

**Prices of Fruits.**—Apples, per doz., 2s. to 3s.; Apricots, 2s. to 3s. per doz.; Cochs, per lb., 2s. to 2s. 6d.; Cherries, per box, 2s. to 4s.; Gooseberries, per quart, 3d. to 6d.; Grapes, hothouse, per lb., 6s. to 15s.; Lemons, per 100, 6s. to 10s.; Melons, each, 6s. to 12s.; Oranges, per 100, 6s. to 12s.; Peaches, per doz., 18s. to 36s.; Pine-Apples, per lb., 8s. to 12s.; Strawberries, per oz., 6d. to 1s.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 3s. to 6s.; French, 4s. to 12s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, each, 6d. to 9d.; Cabbage, per doz., 1s. 6d. to 2s.; Carrots, per bunch, young, 1s. 6d. to 2s.; Cauliflower, spring, per doz., 8s. to 12s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 2s. 6d. to 4s.; Cucumbers, each, 4d. to 1s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Lettuce, per bunch, 6d.; Lettuces, per doz. 1s. to 2s.; Mushrooms, per pottle, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 8s. to 12s.; Button, per quart, 1s.; Parsley, per doz. bunches, 6s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 3s. to 5s.; Potatoes, new, per lb., 3d. to 6d.; Radishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsafy, do. 1s. to 1s. 6d.; Scorzenera, per bundle, 1s.; Shallots, per bunch, 6d.; Spinach, per bushel, 3s.; Turnips, old, per bunch, 6d., young do. 2s.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### THE DESTRUCTION OF PLANTS AT ALEXANDRA PALACE.

OUR readers are already aware of the terrible fire which utterly consumed all but the outer walls of this vast edifice on last Monday, but the newspapers have taken no notice of the loss in valuable plants that took place. Fortunately the numerous exhibition plants shown here were removed, so that only the company's own plants were destroyed. The large number of massive vases erected for the company by Messrs. Austri and Seeley had just been nicely furnished with plants a few days before, and owing to the abundance of Palms, Tree Ferns, &c., the effect was even finer than at the opening show. It is needless to add that all these were utterly consumed, the vases in which they were arranged being split in many pieces. Only a week ago Mr. McKenzie had purchased £800 worth of Palms, Tree Ferns, &c., for the embellishment of the palace—these were all destroyed. The day after the fire we accompanied Mr. McKenzie in an examination of the ruins, and it was grievous to witness the remains of the many Palms, Tree Ferns, &c., here and there amid the chaos of massive iron girders and stays, all twisted and contorted as if they had been so many hoop-irons. Strange to say, the balls of the Tree Fern plants, and the stems of these and Palms seemed to resist the fire more than anything else. There was no trace of tub or leaf to be seen, but the balls were in many cases intact, and also the stem for the length of a few feet. Out of doors the shrubs and trees against the palace suffered, of course, as did the flower-gardens—those against the palace being entirely destroyed. As the whole edifice (900 feet long) was consumed in 90 minutes there was no time to save the more important plants. These would have taken many men to remove them, and all hands had to go to save the pictures. The Rhododendron show of Messrs. John Waterer and Sons, quite near the buildings, escaped without the least injury, which is the more remarkable as their ground was covered with canvas. We understand that no alterations as regard the shows, &c., will take place, and that preparations are already being made for the re-erection of the building. We are sure our readers will regret that such a great loss should have fallen on a company so likely to have done much for the improvement of horticulture, and will unite with us in hoping that the palace may rise again from its ruins more beautiful than before, and that Mr. McKenzie may yet see his commendable taste for high-class plant decoration illustrated in it to the full. Fortunately, a number of unique specimens of tree Ferns and Palms, recently purchased in Ireland, and now on their way home, escaped the general destruction. The large number of glass houses erected by the company are far removed from the main building, and are safe, so that we may hope the out-door gardening will go on without check. We may add that Mr. Ayres' "Alexandra Promenade," which stood within a few feet of the burning building (no person being able to approach within a hundred yards of it, the heat being so intense), sustained little or no injury, only a few squares of glass having been destroyed.

### PLANT GROWING FOR EXHIBITION.

If ever the past—and, shall I say, present—advocates of chromatic flower gardening received a severe shock, it was at the Alexandra Palace Show on the 24th of May. There a profusion of glorious foliage, with a proportionate sprinkling of flowers, made one of the most effective exhibitions that has ever been seen. The effect of the foliage in toning down colour was never so apparent, for had the show been like those of Chiswick and "the Park" a quarter of a century ago, full of flaring banks of Cacti, Azaleas, Pelargoniums, &c., the effect, in that newly-decorated Palace, would have been perfectly depressing. As it was—though Cacti and Azaleas *en masse* were absent—there was a pleasing play of colour from one end of the building to the other, and nowhere too much. Still for all that, I missed many colours which I long

to see. Where were the blues of *Leschenaultia biloba*, *Hoveas*, and *Sollyas* which we used to have? the bright orange of *Podolobiums*, *Dillwynias*, *Pulteneas*, *Gompholobiums*, &c.? the fiery scarlet of Cacti? the bright balls of *Leschenaultia formosa*? the bright rose of *Boronia serrulata* and *Chorozema Henchmanni*? the light airy grace of *Gompholobiums*, and, if need be, of *Zichyas* and *Tropeolum tricolor*? I should feel gratified by seeing the graceful *Coleonema gracile* as Mr. John Fraser used to show it; and I trust that Mr. Baines will some day put as much force into that fine old plant, *Cyrtoceras reflexum*, as he has infused into his grand two-year-old *Ixora coccinea*. The younger kinds of plants, however, must be the stepping-stones to greater variety in our exhibitions. Let them be shown the first year in 12, the second in 15, and the third in 18-inch pots, making it a cardinal point, the plants being equal in other respects, that the smaller pots should carry the palm, and then there will be something for the young cultivator to exercise his ingenuity on besides "bedding out." No one who recollects the gorgeous Heaths which Mr. R. May used to show year after year, and which subsequently passed into the hands of Mr. W. Quilter, of Norwood, will deny the fact that grand Heaths can be grown in small pots. Mr. May's plants were always superbly bloomed, and the colour perfect, and though the plants improved vastly after Mr. Quilter gave them a liberal shift and let loose their pent-up energy, that does not disprove the fact that Heaths may be well grown in comparatively small pots. Taken as a whole, the Heaths at the Alexandra Park Show were not good. Messrs. Jackson's have been for some time past the best; their *E. depressa* and its ally *affinis* being simply in every respect superb. Mr. Ward had a splendid plant of *E. Massoni*, but in many of his other plants the bloom was thin and feeble. Mooting this question to an old grower, he assured me that Heaths had either lost their force or that the peat now procured for them was not so good as used to be obtained a quarter of a century ago. There may be something in that; but still we have had peat of late years in which delicate Heaths have grown as well as could be desired. Peat in some instances may be poor, no doubt it is, but let it be understood Heaths do not object to liquid manure properly administered; on the contrary, they revel in such as is made from sheep-dung and soot or guano, if it is clear, sweet, and not strong. Soft-wooded Heaths, if well rooted, will be benefited by weekly applications of it during the growing season, and hard-wooded kinds may be allowed it occasionally, especially when making their season's growth. But to use manure-water successfully in the case of hard-wooded exhibition plants requires care. Nobody need expect that a sickly plant can be recruited by means of manure-water, though after it starts into new growth liquid manure often assists a plant exhausted by profuse and continuous blooming. The sparse blooming of the large Heaths this season has its cause, and that cause is doubtless want of constitutional force and proper maturation in the autumn. Fine and healthy foliage is a vast improvement to our exhibitions, and as so many people are now scouring the Cape of Good Hope let us look forward once more to having a re-importation of *Banksias*, *Dryandras*, &c., which in Aiton's time abounded so profusely at Kew; their silvery-tinted foliage would be a boon to our exhibitions of the present day. A.

From the report on the progress and condition of the Royal Gardens at Kew during the year 1872, just published by Dr. Hooker, it appears that the number of visitors to the gardens shows an increase of 6,000 over that in 1871, very nearly half the number being Sunday visitors. The acquisitions to the Museums have been considerable, and those to the Herbarium quite exceptional in magnitude and importance, including an extremely valuable presentation by the Rev. C. New of plants collected on the Alpine zone of Kilimanjaro, the only hitherto visited snow-clad mountain in Equatorial Africa; 2,000 Brazilian plants from M. Glaziou, Director of the Botanic Gardens at Rio de Janeiro; and a beautiful collection of Appalachian mosses from Professor Asa Gray of Cambridge, U.S. Among the publications issued during the last year, either officially or by private botanists working at Kew, are the commencement of the second volume of Bentham and Hooker's "Genera Plantarum," the sixth volume of the "Flora Australiensis," by Mr. Bentham; the first part of the "Flora of British India," by Dr. Hooker, &c.

## NOTES OF THE WEEK.

— THE hardy Palm (*Chamærops Fortanei*) is now pushing out its flower masses about London, and the effect of the yellow unopened drooping inflorescence is very striking.

— AT the present time there are nearly 2,000 pots of the Vernal Gentian in bloom in Messrs. Backhouse's nurseries, York.

— LAST Wednesday's show at the Regent's Park was the most enjoyable we have seen during the present season. The old preference of the gardeners and the public for the "park" is easily understood at such a fête. Notwithstanding all our great flower shows and exhibitions in many more pretentious places than the Botanic Gardens, there is no place in which a flower show looks so charming as in the little garden so gracefully designed by Mr. Marnock, nor do any of the newer show-grounds look so well as his.

— WE were much surprised to see the prize offered by the Royal Botanic Society for fine-foliaged herbaceous plants given to a group of *Caladiums*, &c.! It is certainly unfair to word the schedule so carelessly as to induce competitors to show hardy herbaceous plants and *Caladiums* in the same class.

— WE regret to state that the exceedingly fine specimen of the Abyssinian Banana (*Musa Ensete*) in the Palm house at Kew is dying. It has not yet completed the development of its cluster of flowers, some of which at the base began to open twelve months ago. The death of the plant before the maturation of the seed must be a great disappointment, inasmuch as suckers are not produced by this species; therefore propagation can only be effected by means of seed.

— THE culture of the *Euryale ferox* has been resumed at Kew, where a plant may be seen in the same water-tank as that in which the *Victoria Regia* is growing. The leaves of this East Indian Nymphaeaceous plant are rather smaller, but otherwise not very unlike those of the Royal Water Lily. They are circular, spiny above and below, and the under surface skin is purple, and the upper one green; it has also a tendency to flower in a younger state than the *Victoria Regia*.

— ANOTHER addition to the number of metropolitan parks already in existence is that which is just on the point of completion at Deptford. It comprises a space of about 7 acres, situated in a portion of the town inhabited by the poorer classes, to whose service it has been dedicated by the owner, Mr. W. J. Evelyn, of Wotton, Surrey. Within its boundary is situated the ancient manor-house of Sayes Court, which has been restored, and the grounds around it, separated from the park, have been tastefully laid out.

— A DESIRE has been expressed by several florists in the neighbourhood of Birmingham to form a society for the encouragement of the culture of the *Anricula*. The members intend to confine themselves entirely to that class of flower, but do not wish to confine competition to that district; on the contrary, parties from a distance will be allowed to exhibit at the various exhibitions of the society, which is to be called the Birmingham *Anricula* Society. Its secretary is Mr. Geo. Sellon, 96, High Street, Birmingham, to whom all communications and suggestions respecting the best mode of carrying on such a society should be addressed.

— A LITTLE open space in Smithfield, between Bartholomew's Hospital and the new meat market, has recently been embellished by a drinking fountain and statue, and a few beds and borders for flowers. This is what the papers describe as a new city park, and its name is said to be Smithfield Park! A disused bequest, of which the Corporation are trustees, has now enabled this to be done. Sir Martin Bowes, who was Lord Mayor of London in the thirty-seventh year of the reign of King Henry VIII. (1545), founded a charity partly for the benefit of Christ's Hospital, partly for St. Thomas's Hospital, and partly for the conduits of the City of London. The conduits having been discontinued for some time, the Corporation applied to the Charity Commissioners for liberty to erect this fountain and make the garden with the accumulated money, and the necessary consent was given. There are many close streets in the neighbourhood, from which the children have poured ever since the opening, which took place last week. We would suggest a little better protection to the beds, which are much overrun.

— AMONG the many fine plants to be seen flowering at the present time on the rockwork at Kew will be found some interesting and rare kinds. Of these one of the best is *Ranunculus cortusifolius*, a kind seldom met with, which produces large yellow flowers. There is also a good plant of *Aquilegia aurea* just commencing to flower, and the pretty dwarf *Eurothera cespitosa* is likewise blooming freely, as are also the following choice plants, viz., *Iberis juncunda*, *Veronica pectinata*—one of the best of the dwarf species, producing a mass of pretty deep blue and white flowers—and *Androsace lactiflora*, apparently an annual species, with strikingly pretty white flowers. In the herbaceous ground, too, there are several interesting plants in great beauty at the present time, particularly the rare *Dianthus*

*brachyanthus*; *Silene maritima rosea*, a distinct form with flesh-coloured flowers, *Anthyllis Dilleniana*, a pretty species with red flowers, which are produced in great abundance; a plant of the beautiful *Aquilegia cærulea*; *Delphinium nudicaule*, and several showy dwarf species of *Astragalus*, the best of which are purpureus and vimineus.

— WE hear of a Peach with a pyramidal or Lombardy Poplar-like habit, being raised in one of the Southern States of America. It is likely to prove welcome in the shrubbery.

— MR. FREDERICK WILLIAM ROCK, a native of Barnstaple, has offered, at a cost of about £2,000, to present the people of that town with several acres of land, to be laid out in the form of a park.

— MR. E. W. HART says in *Nature* that the flowers of *Viola palustris*, which are nearly unicolorous with a few dark lines pointing to the nectary, are apparently scentless; but after standing for a short time in water in a warm room, they become quite sweet.

— SEVERAL van loads of plants in flower, as well as fine-leaved and ornamental ones, are being sent from Kew to Buckingham Palace, by order of Her Majesty's Commissioners, to assist in its decoration during the approaching entertainment of the Shah of Persia.

— OF the various hardy plants which adorn our gardens with their blooms at this season, none surpass the various species of *Iris*. Fine collections of these may now be seen in the Royal Gardens at Kew, as well as at most of our metropolitan nurseries, in which herbaceous plants are grown in quantity.

— THE Spiguel (*Meum athamanticum*, Baldmoney) is the most gracefully-leaved and freshest-looking little plant now to be seen in the garden. It is a capital subject to plant here and there in borders, being so fresh an accompaniment to the early summer flowers.

— ONE of the most welcome novelties we have seen at our flower-shows for a long time are plants of the hardy *Equisetum Drummondii*. They were grown in pots in frames, and were as graceful as the most elegant *Ferns*. It is probable they will become popular in our gardens, not only in the open air, but in the greenhouse at an earlier period.

— HERBACEOUS plants were shown in very good condition in the Regent's Park last Wednesday. There is a marked improvement in growing these plants for exhibition, though much remains to be done. Some Alpine plants, plunged in mossy *Saxifrage*, which were in wide spaces between them, looked well. This will prove a very effective way of showing well-grown Alpine plants, as the pans would be effectually hidden, the effect of the flowers excellent, and the Mossy *Saxifrages* are easily procured.

**Crystal Palace.**—Tuesday was the nineteenth anniversary of the opening of the Crystal Palace by the Queen, and the authorities availed themselves of the occasion to hold a grand commemoration fête there. A handsome memorial of Sir Joseph Paxton, the architect of the building, was unveiled on the second terrace. The memorial, which has been erected by private subscription, consists of a colossal marble bust 8 feet high and 4 feet 6 inches at the base, carved in Carrara marble by Mr. W. F. Woodington. The pedestal is 11 feet square at the base, and 31 feet high, making the total height 39 feet from the ground. The lower part of the pedestal is in Portland stone; the upper part in Portland cement, in imitation of red porphyry. In the base four incised slabs of Cornish serpentine will be inserted, the first containing a diagram of the principle on which the building of the Crystal Palace is constructed, and the other the following inscriptions:—"Joseph Paxton, born at Milton-Bryant, Beds., 3rd August, 1803; died at Rockhills, Sydenham, 8th June, 1865." "The Crystal Palace was opened by Her Majesty Queen Victoria on June 10th, 1851." And "Si monumentum queris circumspice." The whole monument is designed by and erected under the care of Mr. Owen Jones. The carving on the base is by Mr. Smith; the masonry and cement work by Mr. Charles Bool, and Mr. Euoch Bool. The memorial was unveiled yesterday by Lady Frederick Cavendish, as a representative of the dual House of Devonshire, with which Sir Joseph Paxton was intimately associated. Mr. Scott Russell, as an old friend and colleague of Sir Joseph, made a speech of some length, which, except to the very few who were standing near him, was quite inaudible. In the course of it he described Paxton as a man of noble creative genius, who had devoted his highest energies to securing the well-being and the moral and mental improvement of the people, and added that a better or kinder friend, and a wiser man of business, never existed. Mr. Thomas Hughes, M.P., on behalf of the Crystal Palace Company, of which he is chairman, accepted the gift of the memorial from the subscribers, and expressed the public sense of the great debt of gratitude which they owed to Sir Joseph Paxton, without whose aid the Palace could never have been a success—if even it ever could have existed in its present shape.

## THE ARBORETUM.

### A FINE CLIPPED YEW.

WHEN driving rapidly through the village of Mereworth, a few weeks ago, a very singular and imposing object met my eye, in the shape of the finest specimen of a clipped Yew I had ever seen. It stands in the cottage garden of Mr. Sudds, wood-reeve to Lord Falmouth, at Mereworth Castle, in the village of Mereworth. The illustration is a faithful reproduction from a photograph, and fairly shows the size and shape of the tree, which is remarkable for having, above the evenly clipped portion, a free, natural-looking top, 20 feet high, waving freely. Mr. Sudds writes: "I have clipped the tree myself once a year for thirty-five years. I cut it about the end of August, and after that date it makes no shoots till the following year. Its age is uncertain; the oldest inhabitant remembers it to be about the same size that it is at present." The bole is bare for 6 feet at the base, the clipped portion is 21 feet high, and the top nearly 20, making in all a height of 46 feet. W. R.

### OUR NEWER CONIFERÆ.

BY ROBERT HUTCHISON.

THE thirst for novelty, which may be regarded as one of the prevailing tendencies of the age in which we live, is no less conspicuous in the science of arboriculture than in any other department of the many and varied occupations which engross the mental and physical energies of the present day. As a consequence of this desire to introduce "something new," and to add to the numerous varieties of Conifers which are already well known, and ornament our Pineta and woodlands, the admirers of this interesting class of plants have been accumulating from all quarters, during the last thirty-five years, a hoard of seeds and specimens, both of Coniferous and hard-wood trees, which have been promiscuously planted by their introducers, unfortunately in too many cases without the slightest regard to their suitability to the soils and situations into which they have been imported. We need not wonder, therefore, if many of the efforts to introduce new varieties have proved futile, in so far as the capability of such plants to become valuable timber-yielding trees is concerned, or that the hopes of their planters should have been disappointed in finding that, after much expenditure of time and trouble, not to mention expense, they had obtained only shrubby and half-hardy evergreens where they had expected to rear useful timber trees. Several of the earlier introduced of these recent importations having, however, succeeded well in certain soils and situations, as we shall afterwards specify, arborists have profited by the experience thus gained, and it is satisfactory to observe that, adapting their operations to the requirements and habits of the Pines and trees which they wish to cultivate, planters are now becoming, year after year, more successful in rearing for ornament and use many of those rarer varieties which, some years ago, when less understood, were almost entirely neglected and looked upon as unsuited to the climate and vicissitudes of temperature of the British Isles.

Taking the list of recently introduced Coniferæ, accompanying this report, as containing the principal varieties attempted to be acclimated in Great Britain and Ireland, we may state that the efforts to introduce them have, upon the whole, proved more or less satisfactory and successful, and that in no instance have we discovered in our inquiries and investigations amongst the principal and best regulated Pineta throughout Scotland an instance of any one of the varieties named having been found unable to exist under the influence of our climate. The measure of success experienced in the trial of these new species in a country and climate hitherto unknown to them, as may be inferred from the foregoing remarks, has been very

varied. But where attention has been paid to the rarer and more tender species, in the early years of their introduction, and until they had acquired some height, and become, as it were, established in the soil, there are many examples of their having not only thriven, but of their being now in such a condition as to justify the conclusion that they will hereafter prove valuable for shelter, ornament, and use. In many parts of England there are numerous old and consequently large specimens; for they have been much more generally cultivated south of the Tweed than would be at first supposed. In some instances their utility for economic purposes as timber has been already tried and approved; and in Ireland, where also these rarer Pines are better known than in Scotland, both climate and soil are well adapted for their healthy progress and vigour. Indeed in that country, as in England, there is a much greater number of old specimens than can be found, except in a few special instances, in Scotland. No doubt our Scottish friends have been deterred from trying these "new-fangled" trees from a belief which is still too prevalent amongst us, that most of these Coniferæ are unsuited to our climate so far north; an opinion quite at variance not only with all the experience we have been able to bring upon the matter, but simply absurd when it is remembered that many of the varieties have been introduced from habitats in a much more northerly latitude than that of the British Islands; and that a great bulk of those introduced are to be found in their native regions in latitudes almost similar to those of Great Britain, namely, from 50° to 60° north latitude. Such being the case, we shall in the present paper,

in deference to this opinion, direct attention to the actual capability of these newer Coniferæ, &c., generally, for withstanding the vicissitudes of climate, and thriving in Great Britain, instead of giving individual returns of their exact growth and progress, quoted from the mass of information we have obtained and tabulated from many stations in all parts of the kingdom, in not a few of which instances we found that many of the species had already attained to what may be termed "timber yielding" dimensions, and are thriving vigorously. There are four difficulties to be contended against in relation directly or indirectly to climate, in the introduction and cultivation of the newer Coniferæ in this country, viz.:—1st. The tendency in many of the species to push forth their young buds early in spring, and to continue growing on late in the autumn. 2ndly. The variable character of the temperature of the climate inducing *uncertain* growths, and stimulating in an unequal degree in one season the strength and secretions of the plant. 3rdly. The fogs or hoar frosts to which we are so liable

in spring and autumn, especially in the lower elevations, keeping the young wood and buds damp and unripened, and apt to suffer from the moisture becoming congealed into ice upon the branches and terminal shoots, which are thereby ruptured. 4thly. Wind exerts a very pernicious effect upon many of the newer Conifers, especially in a climate and soil untried by them hitherto.

In reference to the first of these difficulties which planters in this country have to contend against, we may remark that the growth which many of the varieties referred to—such, for example, as *Wellingtonia gigantea*, *Abies Douglasii*, *Pinus insignis*, and in some situations *Picea nobilis*—make in one season, is really marvellous. We have repeatedly seen from 3 to 4 feet of terminal shoot formed in a single year, and this rapid growth, at one time nipped by the frosty winds and nights of spring, and again suddenly checked by the cold of autumn, when in an unripened state, runs considerable risk of total destruction. Happily, however, this habit is lost to a great extent as the plants acquire stature and robust form, and if a little care be taken to shelter them amongst other trees as nurses, until their heads are reared above the dew-line, or hoar frost level, most of the species will withstand with comparative immunity the other extremes of our climate. The Pines most addicted to early growth in spring, and to late growth in autumn, are the *Abies Morinda*, *Pinus cephalonica*, *Pinus Pinsapo*, *Pinus macrocarpa*, and *Pinus Lambertiana*. With regard to the second difficulty mentioned,

Clipped Yew in Cottage Garden at Mereworth.

namely, the variable character of the temperature of Scotland, inducing uncertain growths, and exciting in an unequal degree in the same season the strength and secretions of the plant; in the very severe winter of 1860-61 we found many of the Pines named in the list appended to this paper standing the most intense degrees of frost, while the very same specimens have since been injured by the changeable weather of the spring months, becoming browned in foliage by the continuance of a frosty wind after genial open weather, the growth being doubtless impeded thereby. It is to this cause, we think, that the doubts as to the suitability in relation to climate of most of the newly introduced Coniferæ is to be ascribed, rather than to any uncertainty as to their ability to withstand with impunity the degrees of frost to which they are subjected in Scotland. For example, we found in the memorable winter of 1860-61 the *Cupressus Lawsoniana* at Oxenford Castle, braving uninjured the severity of that season, with the thermometer at its very roots indicating twelve degrees below zero, while the same Conifer has in several instances been found by us since then, browned by the frosty winds and nights of March and April. 3rdly. We stated that the recurrent fogs and hoar frosts of spring were prejudicial to these new Pines. In support of this statement we may mention that, in 1860-61, having had occasion very particularly to examine the state of trees and shrubs, we found that a greater number perished from the effects of the hoar frost and "häär" than from the severity of the frost itself. 4thly. Wind is another great enemy to the progress and establishment in this climate of these rarer trees, especially to those of the Coniferous order. Their ever-green foliage and heavy mass of branches exposed to the rockings of the blast prove most prejudicial to their progress and welfare. The roots become strained and loosened from the earth, and the spongioles of the rootlets ruptured by the oscillating motion of the plant overhead during the frequent gales to which they are subjected, rendering true the saying of a thoroughly practical forester, to whom we lately spoke regarding these newer introductions, which he had in large numbers under his charge, when he said, in reply to our question how his new Pines were thriving with him? "Oh! well enough, if the wind wud gae them peace!"

Another fruitful source of failure to many of the rarer Pines and trees is the practice of planting them when young in too rich soil. With mistaken kindness, they are often placed in leaf-mould, or in "rich" soil made up of decomposed vegetable matter. This only engenders filth about their rootlets and fibres, besides encouraging insect larvæ, which afterwards prove destructive to the young wood of the plant. Many of the species thrive best on a poor soil; for example, the *Aracaria imbricata*, which on a rich loam does not progress nearly so well as it does upon a cold thin soil in an exposed open situation. Among the hills and upper moorlands of Sutherlandshire, this Chilian Pine may be seen thriving vigorously; while in sheltered spots in a loamy soil it has often sustained much damage from the variations of the temperature of our climate. It is quite possible, however, to provide in a great measure against these evils to which our protégés are exposed, and it should be the earnest endeavour of every lover of such beautiful varieties to do his utmost to secure them from those dangers, which are almost the only ones to which, in this climate, they are liable. To remedy the first difficulty, let them be planted in back-lying situations, where neither early spring or late autumn growths will be encouraged; and to ripen the young wood as well as possible they should be placed in open situations, and not in too thick coverts. This will also, in some degree, obviate the second mentioned drawback to their healthy development. As to the remedy for the third objection their natures may have to our climate, it is obvious enough. The difficulty is purely local, and only holds good in very low valleys and inland elevations, where the sun shining brightly during the day thaws the ice upon their branches in early spring or even in winter, and where from lack of altitude the frosts of night are more intense than on the higher neighbourhood; generally speaking, the higher altitudes suit, for this reason, these Conifers best, and where lofty positions have been found tolerably sheltered from wind we have found the finest specimens. Wind is the only enemy to the Pine family, and indeed to trees generally, against which we have no certain remedy. To a great extent, however, with these rarer and finer varieties its ravages may be mitigated, if a little care be taken in selecting positions for them free from the gusts and blasts of the prevailing winds of the district. Farther, in regard to the minor evil we named, namely, that of planting in too rich soil, we may remark that as each variety has its own chosen description of soil in which it thrives best (being its natural one) the custom of making up for its defect, by substituting artificially "made up" soil to promote the growth of the plant, is worse than useless, for after probably a year's growth it will be found that the rootlets have pierced beyond this artificial basin, and have penetrated into the natural soil of the locality, whether suited to them or not; and

certainly in the same ratio in which they may have been artificially stimulated and pushed forward by the made-up fresh soil, will they, on finding their stimulant at an end or exhausted, be retarded by the sudden change or withdrawal of this auxiliary sustenance. A much better mode of aiding their establishment in their new abodes is to pulverise well with the spade the earth of the pits into which they are planted. The bottom earth of these pits should be well loosened and broken, to encourage a free and steady progress in the roots' development, and to enable them to strike deeper and to take that hold of the ground which is their best safeguard against the fury of the gales to which they may be exposed.

Independently, however, of these general causes which operate against the successful introduction and cultivation of the newer Pines and trees, there are other reasons which frequently in particular instances account for many cases of failure. But as they are rather to be found in the individual treatment of the species or plant itself, than in any deficiency in the hardness natural to it, we do not feel warranted, in the present paper, in mentioning such causes in detail. We shall only briefly glance at them; they are practices which we have no doubt time will remedy, as they consist principally in the modes of propagation. For example, many of the finer Conifers grow readily from grafts, layers, or cuttings. *Picea nobilis*, *Pinus ponderosa*, *Cedrus Deodara*, *Cupressus Lawsoniana*, *Wellingtonia gigantea*, and many others are reared and increased by these means. Plants formed in this way, however, are never so fine as specimens, nor so robust in habit, as those grown from seed. Another way in which sickly and unsatisfactory plants are also procured, and which in like manner leads to disappointing results in after years, and aids in bringing discredit upon the genera, is by raising many of the varieties from home grown cones. We have heard gardeners and foresters boast that these new Pines were in some instances "fruiting freely" with them; and we know examples of the *Abies Douglasii*, and others, annually producing cones in this country. At Fingask (Perthshire), for example, the *Cupressus Lawsoniana*, growing in garden loam, and about 7 feet high at that time, bore cones in 1862. At Durris (Kincardineshire), the *Abies Douglasii* was planted from seed in 1810, and is now above 50 feet high, and produces annually "loads of cones." These, however, have germinated few plants. Again, in the same Pinetum, *Picea nobilis*, also planted in 1840, now about 36 feet high, has borne five crops of cones, from which in all about 8,000 plants have been raised.\* At Madresfield Court, in Worcestershire, *Cupressus Goveniana*, about 17 feet high, was, in 1863, covered with clusters of its quaint-looking cones; but from two large seed-pans sown with their produce, only one plant was raised. Now, although these seeds may sprout and grow well enough in the border or pot to which they are committed, they are the progeny of a tree bearing fruit in an abnormal condition; for in their native habitats, these Pines take many years to arrive at such maturity as to produce healthy and abundant crops of cones; and they cannot be expected, under equally healthy circumstances in this country, to produce cones at an earlier age, nor is it prudent to sow the seeds of such precocious parents. The cost of importing fresh seeds, the produce of hardy full-grown trees, will be more than compensated by the vigour of the young plants, and their after condition will probably be such as to free the species from the stigma of being thought unsuited to the climate of Britain.

One word as to the soils which seem best adapted, and have since their introduction been found most suitable, for the healthy development of these beautiful plants. Most of those in our list have thriven best upon an ordinary average loam, of sufficient depth to form a bed for their branching rootlets, with a dry subsoil. The *Abies* do not require so deep a soil as the *Larix*, *Pinus*, *Cupressus*, *Taxodium*, or *Picea*. In too rich soil, they are apt to acquire the habit we have mentioned as so pernicious to their welfare, of making annually too rapid growths of young wood. In a poor soil, if well drained, their habits are sturdier, and although their progress may not be so rapid, it is nevertheless more satisfactory; and when the value of the timber comes to be tested, it will be found that the more slowly the tree has been allowed to develop its timber, and the less it has been induced by overcrowding in too rich soils to attain too early maturity, the harder and more valuable will be the quality of its wood. This must hold good of every variety.

Several species, such as *Abies Merinda*, *Abies Menziesii*, *Cupressus Lawsoniana*, and *Wellingtonia gigantea*, prefer a rather damp soil, upon a wetish subsoil; and all of these varieties, we have observed, have thriven best in such situations. Upon the chalky and limestone

\* Since these remarks were sent to the press, we have learned that this splendid specimen was blown down in a gale. It had, however, we understand, been happily photographed, and the plate presented to the Scottish Arboricultural Society in Edinburgh.

formations, if near the surface, none of them will thrive; and where coal crops out near their roots, they linger out a miserable stunted existence. The *Abies maritima* and *Pinus Lambertiana* have been noticed to grow most vigorously in a sandy free soil, while such a position does not suit most of the varieties we have named.

List of recently introduced Conifers, which may be regarded as generally suitable to the climate of Great Britain and Ireland, ascertained from returns from various soils, altitudes, and exposures, furnished by practical and trustworthy growers of the species named.

Name of Species.	Remarks.
<i>Wellingtonia gigantea</i> ...	Universally vigorous.
<i>Thujaops borealis</i> ...	Very hardy.
<i>dolabrata</i> ...	Not in general cultivation.
<i>Thuja gigantea</i> ...	Very universally hardy.
<i>Lobbii</i> ...	Not so generally grown.
<i>Cupressus Lawsoniana</i> ...	The hardest of the Cupressus family.
<i>Lambertiana</i> ...	Sometimes tarnished by winds.
<i>Goveniana</i> ...	Generally stands well.
<i>Cedrus Deodara</i> ...	Requires care when young.
<i>robusta</i> ...	Better habit and leader than above-named variety.
<i>Libani</i> ...	More adapted for England than for Scotland; thrives well in Ireland.
<i>atlantica</i> ...	Hardy.
<i>Abies Douglasii</i> ...	Worthy of extended cultivation.
<i>orientalis</i> ...	Ditto.
<i>Menziesii</i> ...	Sometimes rather deficient in Scotland.
<i>obovata</i> ...	Not generally grown.
<i>Mertensiana</i> ...	Hardy.
<i>Picea nobilis</i> ...	Hardy in most situations.
<i>cephalonica</i> ...	Sometimes suffers from spring frost.
<i>Pinsapo</i> ...	Sometimes browned in spring.
<i>bracteata</i> ...	Sometimes suffers from spring frost.
<i>Nordmanniana</i> ...	Hardy in most places.
<i>Balsamea</i> ...	Ditto.
<i>canadensis</i> ...	Ditto.
<i>Fraseri</i> ...	Ditto.
<i>grandis</i> ...	Ditto.
<i>Pichta</i> ...	Ditto.
<i>Pinetrow</i> ...	Ditto.
<i>religiosa</i> ...	Sometimes injured by spring frosts.
<i>rubra</i> ...	Hardy.
<i>Webbiana</i> ...	Ditto.
<i>Pinus Laricio</i> ...	Worthy of general cultivation, and where rabbits abound.
<i>excelsa</i> ...	Sometimes doubtful.
<i>Lambertiana</i> ...	Peculiar as to soil and district.
<i>monticola</i> ...	Hardy.
<i>ponderosa</i> ...	Ditto.
<i>insignis</i> ...	Sometimes suffers from frost.
<i>maritima</i> or <i>Pinaster</i> ...	Valuable for coast planting.
<i>taurica</i> ...	Hardy.
<i>Cembra</i> ...	Very hardy.
<i>uncinata</i> or <i>Mugho</i> ...	Hardy.
<i>rigida</i> ...	Ditto.
<i>pyrenaica</i> ...	Very hardy.
<i>anstriaca</i> ...	Ditto.
<i>Sabiniana</i> ...	Usually hardy.
<i>Taeda</i> ...	Ditto.
<i>Taxodium sempervirens</i> ...	Browned by spring winds in some situations, but thriving in many places.

—Proceedings of the Scottish Arboricultural Society.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

**The Single Kerria.**—The double or common form of the Kerria is not so beautiful as the single one which we saw in Mr. Ellacombe's garden, at Bitton, the other day. It does not last so long in flower as the double form.

**Ornamental Trees at Barton Hall.**—In addition to those given last week (p. 432), I may add that a tree of *Magnolia acuminata* at Barton is 10 feet in height, and has a stem 4½ feet in circumference; and that there are also these fine examples of the Black Walnut and Tulip-tree, the latter having a trunk 6 feet in circumference.—W. ALLAN.

**Ilex latifolia.**—In 1852 I planted a small plant of this about 12 inches high, and it has had no protection ever since. The hardest frost we have had since that time was 37°, which browned the points of the shoots; but these I cut off when the plant broke well, and it has made a handsome tree, which most people mistake for a Magnolia, so fine is its foliage.—J. S.

**Chamærops Fortunei.**—May I inquire whether this has often flowered in England? I have a plant of it about 10 feet high, which shows three large flower-spikes—one is fully protruded, and the flowers are now bursting through their envelope. Are the seeds likely to ripen?—W. F., *Ile of Man*. [Chamærops Fortunei often flowers in the open air about London; but we suspect it will only ripen seeds under glass.]

**Exochorda grandiflora.**—You have recently recommended this beautiful May-flowering shrub as a plant for walls, and a capital subject it is for that purpose. With me, however, it forms handsome bushes in peat soil in the London district; and, as it flowers later in this way than on walls, I get a more prolonged bloom than if I grew it in one way only. There are few uncommon shrubs more worthy of a place in a choice collection of early-blooming shrubs than this.—V. E. R.

**Bamboos.**—In an article in THE GARDEN, of May 31, on "Forest Vegetation in Siam," it is said:—"We have seen hardy Bamboos producing an almost equally good effect in the southern parts of England and Ireland." I wish to inquire what species of Bamboos (other than *Arundinaria falcata*) were employed, and to what dimensions they have attained. I have found great difficulty in procuring any species of the tall-growing Bamboos, except the one I mention, which with me has attained a height of 14 feet.—W. F., *Ile of Man*. [You will find a descriptive list of hardy Bamboos, containing all the information you require, in Volume II. of THE GARDEN, p. 316.]

GARDEN DESTROYERS.

CROCUS ENEMIES.

THE Crocus is subject to many attacks from enemies, owing to its being in the ground in winter and commencing growth early. One may make proper preparation for it, and plant the bulbs in good season to little purpose if we have not previously trapped or otherwise exterminated the long-tailed, white-bellied outdoor mouse. I will not call it the field mouse, as this active little depredator is to be found everywhere outdoors—in the garden, field, plantation, and hedge—wherever, in fact, shell seeds, nuts, acorns, or Beech mast are to be found; indeed, any kind of seed, such as those of the Laurel, Bay, Cherry, Thorn, Holly, and the like, they will collect and hoard in large quantities, and as soon as Pea and Bean sowing has begun, and they have commenced to grow, they will attack and dig them out. They are, however, easily trapped with Peas first soaked and grown from a quarter to half an inch, and then threaded, two being allotted to each trap, left an inch apart on the thread, so as to afford room for the mice to put their mouths to and bite asunder the thread. This is cut in lengths of 10 inches, a knot being tied at each end and pulled into two slit sticks, which are run into the ground to hold up the Peas. Currant shoots or Raspberry canes, cut into one-foot lengths, may be used for this purpose, placed conveniently for the mouse to get at and nibble the thread asunder. On this rests one end of a brick, the other being on the ground, and when the thread is gnawed in two the brick falls on the mouse and kills it. Hundreds of such traps may be set in the course of a day. They are the most simple, inexpensive, and surest mouse-catchers ever yet invented. If these mice are allowed to ramble about, they are pretty sure to attack Crocuses the very first night

Garden Mouse-trap.

after they are planted; and not only that, but they will continue to feast on them, old and young, as long as they are in the ground, whether in bloom or not. They only eat the bulbs, and leave the grass or foliage. But if the big bull-headed grass mouse should make his appearance after the Crocuses have thrown up their young grass above ground he will graze on that at the early growing season, and so will the sparrow. The chaffinch is also very fond of picking off the newly-made shoots. When Crocuses are plentiful near plantations and shrubberies, the wood-pigeon is very destructive to the young grass or foliage in the months of February and March. Rooks, too, are fond of Crocus bulbs at any time of the year when they can find them to dig out. But of all birds pheasants are the greatest enemies to Crocuses, often ronting up whole beds of them, in any and every stage of growth, generally during the dusk of the morning and evening, before sunrise and after sunset. The squirrel and the rat, also, eat the bulbs when ripe; and, after they are stored away, if not guarded securely, house mice will carry off and hide away the whole of the bulbs that are worth anything. It is truly astonishing how quickly they will remove a large quantity. While the Crocus is growing in early spring, in mild moist weather, the shoots underground are subject to the attacks of the little lean tough black slug that travels up and down the earthworm drains; and as soon as the grass of the Crocus makes its appearance above ground, if white and grey slugs and snails abound, they will also feast on the young foliage: those, however, who know something of natural history and the habits of such intruders, soon learn how to guard against all and every kind of depredator, and are but seldom caught napping. Besides the host of intruders just named, the wireworm and various other ground grubs will also attack Crocus bulbs in various stages of their growth. The accompanying is an illustration of the trap mentioned above.

It consists in thrusting two sticks into the ground, fastening to each a thread with Peas on it, and then suspending a brick over them. The mouse in getting at the Peas nibbles the thread asunder, and thus effects his own destruction. A slate should be laid on the ground for the brick to fall on, and the bait need not be higher than about 2½ inches from the ground.

JAMES BARNES.

## THE GARDEN GUIDE.

### SUFFOLK.

#### LIVERMERE PARK.

THE park here contains about 500 acres, between 300 and 400 head of deer, and is remarkably well wooded. The house is surrounded by shrubberies and a pretty flower garden. There is also a nice range of glass houses, consisting of two or three Vineries, one of them containing a very fine Fig tree of great age and size, and sure fertility, two good crops being obtained from it every year. The centre of the range is occupied by a fine conservatory—light, elegant, and lofty. Livermere house used to be famous for its Magnolias (*M. grandiflora*) and *Wistaria sinensis*, but the winter of 1859-60 cut them nearly to the ground; they are, however, rapidly recovering. On the lawn are a few nice Cedars of Lebanon. The kitchen garden, which is pretty extensive and surrounded by shrubberies and pleasure grounds, is about half a mile distant from the house, from which it is hidden. The chief features of Livermere are its extensive park, already alluded to, and a noble lake, near the garden front of the house.—Miss Broke, a minor; resident trustees, Captain and Mrs. Horton; gardeners, Mr. Munday, flower garden, Mr. Lockhart, kitchen garden. Five miles north-east from Bury St. Edmunds.

#### AMPTON PARK.

This joins Livermere, the lake just alluded to forming the boundary between them. The two parks comprise over 700 acres, and from Ampton fine views are obtained of the larger park of Livermere. The pleasure grounds round the house at Ampton are interesting and extensive. On the lawn are some noble Cedars, shrubberies stretch away in different directions, and the flower garden is well furnished and tastefully laid out. Near the house are some old-fashioned conservatories, and the chief glass houses are, however, in the kitchen garden, between which and the mansion is a public road. In this department are some fine Pear and other fruit trees, the walls being remarkably well furnished. Good Grapes are also produced in the Vineries. Recently some orchard and plant houses have been erected, and there are useful pits, &c., for the growth of plants for furnishing the conservatory, cutting, and bedding out.—Hunter Rodwell, Esq.; gardener, Mr. Snelling. Distance from Bury St. Edmunds, 4½ miles north.

#### STOWLANGTOFT HALL.

This has recently been rebuilt, and new gardens made; but the gardens around the site of the old hall and the old kitchen gardens have been retained. These lie almost at the bottom of a valley, where the ground is rich and crops plentiful and good. The fruit and plant houses, which are numerous, are also here; and a very pretty gardener's cottage, placed near to the frame and forcing ground, looks out on a pretty flower garden. The new hall, which is built upon a much higher site than the old one, is a noble building. Attached to it is a handsome conservatory, lofty and elegant, and well furnished with fine plants. In front of the house is a geometrical flower garden, bounded by a terrace walk and a retaining wall; then follow the park and the old gardens in the distance.—Col. Wilson; gardener, Mr. Galletley. Two and a half miles from Ixworth, six and a half north-east of Bury St. Edmunds.

#### ROUGHAM HALL.

This handsome mansion, in the Tudor style, has a striking appearance viewed from the public road. It overlooks the Rougham Downs, and is associated with pretty pleasure grounds, a small flower garden, a fine span-roofed conservatory, and woods filled with Rhododendrons, which, in the peat soil, here literally grow like weeds, and sow themselves in all directions. At this season of the year the Rougham Rhododendrons are the "lions" of the neighbourhood; not only the woods but even the open heath being literally aglow with them. The greater part of them are of the ponticum breed and its commoner hybrids. Generally speaking, Rhododendrons are neither plentiful nor fine in East Anglia. They don't like the chalk below and the dry biting air above. The trees, especially the Oaks at Rougham, show by their stunted appearance that they have long ago bottomed and exhausted their shallow root runs. The Rougham road runs between the hall and the kitchen garden, which is of considerable extent, nicely walled round, well furnished with fruit trees, especially Pears, and contains several

good Vineries. The soil here is of a more loamy and very different character from the hungry peat in which the Rhododendrons delight.—Captain Bennet; gardener, Mr. Pollard. Distance from Bury St. Edmunds, 4 miles.

#### DRINKSTONE PARK.

The gardens and pleasure grounds here have been much extended and improved of late years. The soil, a strong clay, is admirably suited for Roses, and the finest blooms of Cloth of Gold, perhaps ever seen, used to be gathered from a plant which grew and flourished for years on the front of the mansion; a severe winter, however, cut it down, and it has never thoroughly recovered. Maréchal Niel, which did almost equally well, shared the same fate—a fate, by the way, to which this glorious Rose is peculiarly liable. For a season or two it makes shoots like those of a Willow; the frost nips them, and then the plant does little more good. Most of the best Tea Roses do well outside at Drinkstone, and the outside walls of most of the hothouses are clothed with them. The walls are both studded and wired, so that Roses are trained thereon without injury. Roses, Perpetuals and others, are also extensively grown in a pretty Rosery near the flower garden, as well as more perfectly for exhibition in the kitchen garden, well manched with manure. Fine-foliaged and stove and greenhouse plants are also well grown in some good modern span-roofed houses at Drinkstone, where there is also a new range of Vineries and a Fernery. The walls of the Fernery are lined with virgin cork, and the house altogether is tastefully laid out and furnished. The Vineries were planted last year with eyes on Thomson's plan, and they made fine rods, that soon reached the top of the house. There are also here a good Peach case, well furnished; various pits and frames, and a pretty gardeners' cottage, smothered with Roses. Many new belts of shrubs and trees have been recently formed, in some of which the rarer kinds of Conifers, in some cases, have overtopped the nurses. Wellingtonias, Piceas, Pinuses, &c., have also been grouped and dotted about the park in choice positions, and are rapidly growing into beauty. The park contains nearly 250 acres, and is richly wooded. The view from the house is rich and varied, embracing a fine lake, crowded with white water Lilies, and margined here and there with groups of Pampas Grass.—Captain Powell; gardener, Mr. Nicholls. One mile from Woolpit, two and a half miles from the Elmwell Station of the Great Eastern Railway; eight miles, east by south, from Bury St. Edmunds.

### SONG OF THE FLOWERS.

SEE, we come dancing in sunshine and showers,  
Like fairies or butterflies—bright young flowers;  
O'er vale and o'er mountain, tho' ever so steep,  
Go wander—we'll still on your rambles peep.  
Far from the city and smoke live we,  
With our neighbour, the rugged old forest-tree,  
Who, wrapp'd in his mantle of Ivy green,  
Looks gay,—for his wrinkles are never seen.

With the zephyrs we dance  
'Neath the bright warm sun;  
But the moon's pale glance  
Bids our sport be done.—

Then we close our petals, nor, winking, peep  
Till the morning breaks our perturbed sleep.

Blooming in sunshine, and glowing in showers,  
Dancing in breezes—we gay young flowers!  
How often doth an emblem but silently tell  
What language could never speak half so well!  
E'en sister flowers envy the favoured lot  
Of that blue-eyed darling—"Forget-me-not."  
Her name has now grown a charmed word,  
By whose echo the holiest thoughts are stirr'd.

Come forth in the spring,  
And our wild haunts seek,  
When the wood-birds sing,  
And the blue skies break!

Come forth to the lull—the wood—the vale—  
Where we merrily dance in the sportive gale.

Oh! come to the river's rim, come to us there!  
For the white Water Lily is wondrous fair,  
With her large broad leaves on the stream afloat,  
(Each one a capacious fairy-boat),  
The swan among flowers! how stately ride  
Her snow-white leaves on the rippling tide;  
And the dragon-fly gallantly stays to sip  
A kiss of dew from her goblet's lip;

Oh! come in the glow  
Of the long summer's day,  
When the cool waves flow,  
And the zephyrs play;

Oh! dwell not in the cities, mid care and care,  
But come to the river's rim, come to us there!

—Anon.

## THE GARDEN IN THE HOUSE.

### BASKETS OF ROSES.

Roses in a cut state are always welcome, and a tastefully arranged basket of them constitutes one of the most elegant floral ornaments that can be obtained for the decoration of the drawing-room. Three important points may be urged in their favour. Firstly, Roses will keep fresh for a comparatively long time; secondly, they are not difficult to arrange; thirdly, they can be bought for a small sum, if not growing in one's own garden, and any one who does possess a garden, large or small, is sure to have Roses. Baskets made of different materials for holding ordinary cut flowers can be bought, but for Roses I prefer those made of glass, as the clear crystal shows up the rich colours of the Roses and their variously tinted foliage better than any other material. In glass baskets the flowers should nestle among Moss instead of sand, which, when seen through the glass, has a bad effect.

The arrangement as to colours must be, of course, according to taste; some prefer their Roses to be all of one colour, such as crimson; others like white or pink, and some mixed colours. In the accompanying illustration, *Maréchal Niel* has been used in the form of full-blown and half-opened buds, set off with foliage of the same and the young brown foliage of other Roses. Round the handle is twisted a spray of *Lycodium scandens*, but a piece of variegated Ivy, Japan Honeysuckle, or any thing of that kind, would look quite as

Basket of *Maréchal Niel* Rose.

effectively. Opinions differ, I know, as to the propriety of mixing Ferns with Roses in preference to their own foliage, but for my own part I prefer their own leaves, when the arrangement consists wholly of Roses. If of mixed flowers, then light Ferns might be used with advantage. I need scarcely add that besides Roses there are many other flowers that might be arranged in baskets for the drawing-room, and with excellent effect; but I have used Roses to illustrate my subject on this occasion, owing to the high estimation in which they are held, and their suitability for the purpose now under consideration. A. II.

### FLOWERS FOR CEMETERIES.

As in all English-speaking lands the cemetery is to some extent a garden, and often, as in America, a noble and well-kept garden, a few words on some plants suitable for it may not be without value. If plants that look well all the year round are more *à propos* for any one spot than another, that is in the cemetery; but, notwithstanding this, the gaudy flowers of the "bedding out" garden are frequently planted on graves; while far from suitable in tone, they perish in winter, and frequently present a miserably ragged aspect after being cut down by the autumnal frosts and rains. Infinitely better are flowers of spring, whether they disappear in winter or no; and, better still, those which look well all the year round, irrespective of their flowers. There are plenty of plants eminently suited for this very purpose, cheap, hardy, and easily obtained; and some of them of such vivid green, even in the middle of winter, that they could not fail to

contrast most favourably with their sculptured surroundings; and what more suitable for the grave than humble plants which perish not during our cold and dreary winters, but which glisten into a deeper green in the November blasts, and emerge from the hardest frosts and deepest snows full of life, and ready to smile into flower under the earliest glances of spring.

The kind of plants that I would particularly recommend are those known as alpine—hardy evergreen herbs of northern and elevated regions in temperate climes. First among them, from its excellent constitution and the readiness with which it may be procured, I would place the evergreen *Iberis saxatilis*, which forms neat little evergreen bushes, looks fresh at all seasons, and becomes a perfect sheet of snowy beauty in early spring. It grows everywhere, and will be found to do better on and around graves than in the shady and half-shady positions in which it is usually planted. This common kind is easily obtained, and is as useful as any; there are several others equally useful, *I. corifolia* and *I. corceafolia*, which blooms later than the others, bearing large and fine pure white flowers. Suppose it is wished to make a dwarf evergreen edging round a grave or its railings, there is nothing which will equal the first or commonest of these plants; once planted evenly in line it will soon form a compactly spreading hedge, and remain in good condition for years without any attention whatever. Should it at any time get too large or spreading for its position, it may be clipped in closely with a small shears; and it bears clipping as well as a Privet hedge. Along with it might be associated the dwarf, creeping, compact, and evergreen *Aubrietias*, which become masses of purplish blue in spring. Being much dwarfer plants than the *Iberis*, these would require a slightly different position. The *Iberis*, for instance, might be in the centre, and these, with the dwarfer subjects, towards the edge. All the *Aubrietias* are suitable; they only differ a little in colour. The white *Arabis albidia* would also be very useful in this way. The dwarf yellow alpine Wallflower, *Cheiranthus alpinus*, forms a very neat and compact bush all through the winter, and produces masses of clear, pure yellow in spring; but it is not a very permanent plant in heavy soils, and we should, in this instance, choose the most permanent. A most exquisite plant for the head or foot of a grave is *Anthericum Liliastrum* (St. Bruno's Lily). It grows from 1 to 1½ foot high, and bears large, pure white, Lily-like flowers. For forming a carpet of snowy flowers *Campanula carpatia alba* ranks next to *Arabis albidia* in profusion of bloom, and is perhaps superior to it in compactness of growth. Other effective white-flowered plants are *Vinca minor alba*, which blooms from spring all through the summer, *Thlaspi latifolium*, *Viola cornuta alba*, *Potentilla alba*, *Phlox subulata alba*, *Anemone alba*, *Arenaria montana*, *Campanula caespitosa alba*, *Hutchinsia alpina*, *Scilla nutans alba*, and *Smilacina bifolia* and *stellata*.

*Silene alpestris* combines every good quality which could be desired in a plant of this kind; it is as hardy as the common Daisy, forms a low-spreading evergreen tuft, and becomes a mass of the purest and prettiest snow-white flowers in early summer. It will form a charming companion for the *Aubrietia*, and is easily raised from seed, or may be had easily as ready grown little plants in any nursery where alpine plants are grown. In the very interesting *Sedum* tribe a good many dwarf things will be found suitable; the English *Sedum album*, for instance; the large glaucous *S. sempervivoides*, the green *Sedums reflexum* and *sexangulare*. Indeed, nearly every hardy *Sedum* will be found suitable, and is pretty certain to look well at all seasons. Of course these dwarf plants require to be kept clear of weeds, and free from the company of larger and more straggling plants, which choke and disfigure them. The *Sempervivums*, or Houseleeks, also afford a few exceedingly permanent and pretty plants, which generally look better and more compact in winter than in summer. Some are green and others glaucous—all interesting and neat. *S. californicum*, glaucous, with each leaf tipped with chocolate colour; *S. montanum*, dwarf, neat and green; *S. globiferum*, forming round little balls of leaves, green with a pinkish tinge, and scarcely rising above the ground, will be found among the best, though every one of the hardy ones will be found suitable.

The *Saxifragas* are still better than the preceding kinds, in

consequence of their deep and vivid green. The mossy Saxifrages are particularly remarkable for assuming their deepest and finest verdure when winter commences its reign, and almost every other plant begins to look ragged and decaying, or has lost its leaves. These, then, in nearly every instance offer attractive objects for planting on and near graves. It is useless to specify individual kinds, for nearly all are equally good, and differ mainly in their tone of green, and slightly in size, one or two scarcely growing more than an inch and others attaining the dignity of three, four, or five, and even a foot high, when old. The native *S. hypnoides* and its varieties are as good as any; while, if the silvery kinds are fancied, and very beautiful they are, looking as well or better at Christmas than at midsummer, *Aizoon*, *pectinata*, *crustata*, *pyramidalis*, *Hostii*, *intacta*, and others closely related to them will be found to suit admirably. Those who do not know these encrusted Saxifragas may be the more favourably disposed to them when it is stated that their tiny leaves are margined with a row of silvery or white dots, and the leaves being very abundantly and compactly produced, the plants present a singularly neat appearance. A turf of these here and there among the emerald green kinds would look very beautiful. Even the Killarney Saxifrage (the London Pride) and its allies would do, but scarcely so well as the mossy and silvery sections, which generally produce white flowers in spring or early summer. All the preparation necessary for these plants is a slight lightening of the surface soil with sand where heavy, and that is rarely necessary in ordinary soils.

Among these pretty alpine, &c., I would drop here and there a bulb or plant of some chaste and pretty spring flower, like the common or Crimean Snowdrop, *Hepatica alba*, the white and delicately-striped Crocuses, *Bulbocodium vernum*, *Scilla bifolia alba*, *Leucopodium aestivum*, *vernum*, and *pulchellum*, *Erythronium Dens-canis album*, and any other spring flower that may be admired and obtainable. A few Violets would be very suitable if the soil were one in which they would flourish, which is not the case on heavy clays. Finally, a few neat dwarf and hardy shrubs—compact tiny evergreens—are excellent. In this way nothing surpasses *Erica carnea*, which is a perfect mass of charming flowers in spring, and hardy and free in almost all soils. Some of the dwarf and curious varieties of the common Ling, which are to be had in good shrub nurseries, are also good; while the pretty little Partridge berry (*Gaultheria procumbens*), with its bright red berries in winter and tiny close growth, cannot fail to charm. In a peat soil a good variety of dwarf Ericaceous plants might be tried. On nearly all soils the Bearberry (*Arbutus Uva Ursi*) will trail its recumbent evergreen growth healthfully along; and, where there is considerable space, some of the dwarf hardy evergreen Rhododendrons, the bright-berried *Skimmias*, and dwarf green tapering Conifers, like the *Retinosporas*, may be tried with great advantage, with a few of the Ivies to train up rails, along chains, &c.; not to speak of other dwarf, evergreen, and interesting shrubs which may be found by examining any good shrub nursery.

From the limited space generally around graves, the planting of large or free-growing things is not to be recommended. The general planting with the larger trees of suitable character should be attended to by the managers of the cemetery. There are a great many Conifers and other trees and shrubs which look very well in a young state, but which soon attain large and unsuitable dimensions; and these should be discarded as unfit for the surface and immediate surroundings of a grave. It is not sufficient to see the aspect of the plant when young; we should inquire also as to its usual ultimate development.

I.

#### THE FLOWERING OF PLANTS.

EVERY addition to the organs of nutrition, besides adding to the bulk of a plant, increases its power of obtaining food. Apart from accidents, therefore, there would seem to be no limit to the growth and increase of plants but the failure of an adequate supply of nutriment. The reproductive organs, however, on the other hand, stop any further growth in the part of the axis which they terminate; and making large demands on the resources and accumulated nourishment of a plant, supply little or nothing in return. Reproduction is, therefore, an essentially exhaustive process,

and does not commence till the plant is provided with a store of accumulated food sufficient to sustain it. It is these stores of food which we especially appropriate in utilising vegetable produce. In the Turnip, for example, the first year of growth is occupied chiefly in accumulating nutritious matter in the enlarged root. The aerial part of the plant is simply a tuft of leaves attached to an axis, with undeveloped internodes. In the following year the growth is all diverted from the root to the ascending axis, which grows rapidly, drawing its supplies from the root, which wastes, becomes hollow, and contains finally little except insoluble fibre. So complete is usually, in the case of biennials, the drain of nutritive matter in the flowering and subsequent maturation of the seed, the plant has neither strength nor material remaining to enable it to put out fresh organs of nutrition, and it consequently dies. The period of flowering varies greatly in different plants. It depends partly on constitutional habit; and this may depend on external conditions. The perennial plants of warm countries may become annuals in colder ones, as is the case with the Castor-oil plant and the Marvel of Peru with us. It may also depend on the amount of accumulation of food which flowering requires in each case. An annual blooms a few weeks after its germination, and the nourishment it possesses being completely exhausted, it is destroyed by the process. Yet its existence may sometimes be prolonged over more than one season, if the flower-buds be regularly removed, as in the Tree Mignonette of gardeners. The flowers of woody plants which bear large and fleshy fruits are not produced from terminal, but from lateral buds, which rest upon the "seasoned" wood of the previous year, in which nutritive matter is accumulated. Fruit trees also exhibit the effects of exhaustion when, after an extensive crop, especially of the late kinds of fruit, the trees fail more or less the succeeding year, though they will bear more abundantly in the year following their rest. The period of accumulation in some plants is very long, and the subsequent exhaustion correspondingly fatal. The American Aloe, which flowers in its native climate when only five or six years old, only does so with us after the lapse of a period longer in proportion to the retarding influence, and sometimes as much as from fifty to seventy years. The Talipot Palm, which lives to a great age, and bears leaves 30 feet in diameter, flowers only once, and then perishes. The rate of growth of the inflorescence is usually much more rapid than that of other organs. The flower-stem of the American Aloe, even in our conservatories, grows at the rate of a foot a day, and the plant's store of food is proportionately rapidly used up. The accumulation of nutriment usually takes place in some part of the axis. In the Turnip, Beet, Radish, Carrot, and many other cultivated plants, it is contained in the enlarged root, and the tendency to enlarge seems to be one which may be pretty readily induced, and afterwards increased by cultivation. In other cases the stem becomes loaded with amylaceous or saccharine matter, as with the Sago Palm and Sugar Cane; or the succulence of the whole plant may become sufficient to supply the inflorescence, as with the American Aloe, the sweet juice of which is made by the Mexicans into an intoxicating drink. The store, wherever situated, will obviously attain its maximum just before or at the time of the first appearance of the flower-buds. It rapidly diminishes as they open. The stalks of the Sugar Cane are cut just before the flowers expand, and the Sago Palm is fit for cutting down at the first appearance of the flower-spike. The chemical changes which accompany flowering are apparently similar to those which accompany germination. The circumstances of the two processes are indeed in many points identical. In both there is rapid vegetable growth, drawing its supplies from previously accumulated stores. These usually at first contain some form of starch, which in each case first passes into the soluble form, and afterwards into dextrin and sugar. The latter stages, which take place probably more immediately in the neighbourhood of the flower, are accompanied by the absorption of oxygen, the formation of carbonic dioxide, and the evolution of heat. In ordinary plant growth, the food of the plant is highly oxidised, and its assimilation is consequently attended with the evolution of oxygen. In germination and flowering the food supply of the developing parts contains comparatively little oxygen, and its assimilation is at any rate accompanied by the separation of part of its carbon as carbonic dioxide, while oxygen is absorbed. An experiment devised by Persoz illustrates the oxidation which exists during flowering. If the roots of a translucent plant, like Balsam, are watered with a solution of logwood, the colouring matter is reduced when absorbed into the roots, and loses its colour. When, however, it reaches the petals it is again oxidised, and its colour again appears. The fragrant odour of the Meadow-sweet, which is attributed to the presence of salicyl hydride, is stated by Buchner to be furnished by the oxidation during the expansion of the flower-buds of the salicine which they at first contain. This conversion is artificially imitated when salicine is oxidized by means of potassium dichromate, and salicyl

hydride is formed. The evolution of heat in blossoming was first observed by Lamarck in 1777, in the spadix of *Arum italicum*, where an immense number of blossoms are crowded together. It was afterwards shown by Saussure that the heat evolved was in direct proportion to the oxygen absorbed. According to Vrolik and De Vriese, the temperature has a regular periodicity, and attains its maximum in the afternoon, between two and five.—*How Crops Grow.*

## THE FRUIT GARDEN.

### ARRANGEMENT OF FRUIT HOUSES.

The general plan and arrangement of fruit houses depends in every case so much upon situation and circumstances, that it is scarcely possible to offer any suggestions that would be generally applicable on that head. There are, however, certain rules and other matters connected with the effective working arrangements of an establishment which should not only be duly considered, but adhered to as far as possible.

The best site for a block or range of houses is a level one. A gentle inclination to the south is not objectionable; but when the ground slopes either to the east or west it should be made level if practicable, otherwise the structures must necessarily occupy different levels, which is very inconvenient, as the houses, if in a line, shade one another; flights of steps at the various landings obstruct the workmen in their duties; the heating apparatus works unequally; and externally the

Section of house with pipes badly arranged.

general effect is impaired. Whatever kind of site may be chosen, it should have a free and open exposure to the south, east, and west. The protection afforded by trees or rising grounds against prevailing winds should be taken advantage of, but these objects should not encroach so closely upon the houses as to obstruct, in any degree, the light and sunshine. This applies more particularly to span-roofed houses, which, as their shape denotes, are intended to utilise the heat and light of the sun to the utmost. Consequently, when they are placed with their ends abutting, it may be, against a high wall or in the shade of trees, the advantage of the span-roof is to a great extent lost; indeed, it is quite possible in such a case that it may be less serviceable than an ordinary lean-to house. The span-roof, considering the greater extent of active radiating surface which it presents, is not an economical form, unless it is placed where it can have sunshine for as long a period as possible every day. Gardeners are familiar with the injurious effects of shade upon plants requiring much light, and especially upon the inmates of glass houses. The far-reaching shadow of tall trees upon a Wheat field may be traced by the later ripening of the grain for nearly a hundred yards out, and as distinctly as the sunshade upon a dial; what, therefore, must be the effect upon a house of Vines or Peaches, for instance, which loses the sun's rays shortly after midday, and what the extra consumption of fuel? Some prefer keeping plant and fruit houses apart, but this is not a necessary arrangement. Besides, plant structures may be introduced with good architectural effect to divide the different blocks, and break that sameness of appearance which fruit houses generally assume. Internally they also pleasingly diversify the interest, and may be placed so as to afford a ready and agreeable introduction to the range, and at the same time prevent currents and draughts of cold air from reaching the

warmer forcing houses. Such arrangements lessen the necessity, too, for growing stove and greenhouse plants in the fruit houses—a practice which may be recommended on the score of appearances, but on no other grounds, if freedom from insect plagues, which almost defy remedial measures when once they are established, be any consideration. In order to facilitate all work connected with the formation and keeping of inside fruit-tree borders, and the transfer of large quantities of soil and materials, it is necessary that the paths and doorways in all the houses should be wide and roomy, whatever may be the

Good arrangement of pipes.

size of the houses. This will also insure convenient walking room; for there need be no impediments to fruit houses at all times forming part of an agreeable promenade to the proprietor and his friends.

Ample heating power should in all cases be provided. Frequent attention to fires, waste of fuel, and scorching pipes, parching up everything in their neighbourhood to an injurious extent, will be avoided by a little extra outlay for boiler power and piping at the beginning. This and the stoking are matters of quite as much importance as the kind of boiler that should be employed. The plan of carrying all the hot-water pipes round the front of the house on the block principle is bad, for in that case the heat is very unevenly distributed; neither is it a good plan to have them sunk below the floor level between retaining walls—in an open drain, as it were—for the heat is absorbed by the cold walls. This is especially the case in pits where the pipes are often confined one above another in a narrow space between the bed and the cold outer wall. Under such circumstances, during a cold night, plants are roasted at the front of the pit, while the back has probably to be covered with mats to exclude frost. In such a case the better way would be to carry the flow pipe round the back of the pit, and return along the front, or *vice versa*. In wide houses the piping should be distributed over the floor—say two rows in front, two in the middle, and two at the back of the house. By this arrangement we secure not only a more even temperature throughout the house, but we save heat; for, if all the pipes were taken round the front

of the house (I am speaking of lean-to houses), the direction of the hot-air current would be directly towards the cold glass roof, which would, by conduction, at once lower its temperature greatly, and the current, following the roof to its apex, would be spent without materially affecting the temperature of the house. On the other hand, the warm current from the row of pipes along the middle of the house must heat a much greater volume of air in its passage to the roof, having to traverse more space; and so on, within certain limits, according to the distance of the pipes from the glass. This is exemplified any time in a lean-to Vinery or Peach house during a frosty night. The condensed vapour upon the glass never freezes above the front row of pipes; the position of the middle row is just discernible upon the frosted glass; while the back row produces

no visible effect, its heat power being diffused in its ascent. The arrangement of the heating apparatus should therefore be studied according to the form of the house, in order to utilise to the utmost every inch of heating surface.

An equally important matter is the supply of water to fruit houses. Of the many duties which have to be entrusted to subordinates, watering is one of the most important. It requires not only skill and experience, but an amount of painstaking attention which can hardly be expected from those who have only a temporary interest in the work, unless facilities exist which reduce the strain upon both brain and sinew to a minimum. During pressure of work a man may be tempted, even in the best regulated establishments, to neglect or only half do his work, if things are not handy, who would probably avail himself of conveniences did they exist. When a man has to carry hot and cold water from different sources, perhaps a hundred yards apart, before he can water a house of Pines or a Vine border, as the case may be, depend upon it he will make as little as possible serve his purpose. The water supply should, therefore, be both ample and convenient. All rain water should be collected. In nine cases out of ten no provision is made for saving more than a fractional quantity of this valuable supply, which in ordinary seasons would go far to meet all demands; the best plan, wherever the supply comes from, is to provide large tanks in each house or block of houses. Under the paths is a convenient place for these, and they should be covered over. They may be built of brick, and lined either with cement or concrete. A nine-inch brick wall, lined with one coat of cement, makes as cheap and lasting a tank as can be desired. The large tanks will provide water at a suitable tem-

Good arrangement of pipes.

perature for what are termed cold houses, such as late Peach and orchard houses, and for this reason they should be accessible by dip-holes in every house; but for the warmer houses, such as Pine stoves, early Vineries, and Melon houses, &c., additional cast iron tanks, large enough to hold a hundred gallons or more each, should be provided, and these should be placed conveniently above or alongside the hot-water pipes. Attached to each should be a handy pump communicating with the main tank under the floor, for the purpose of filling them once or twice a day, and providing a plentiful and convenient supply of water at the same temperature as that of the house. Where there are long ranges of Vineries with inside borders, or extensive Pinerics and plant houses, such arrangements will be found to be by far the most economical and serviceable in the end.

The next matter is the supply of soil and shed accommodation, upon which a word or two should be said. The shed room should always be in proportion to the amount of glass, and the potting and soil sheds should be near or behind the warmest houses. In some places they are heated, which is a very good plan, in order that the house and soil may be kept at a proper temperature for potting any thing that may be brought out of a warm house. The potting sheds should communicate, by means of inner doors, with the houses, that there may be no carrying of tender plants to and fro in the open air when work has to be done. As to the supply of soil, it is unreasonable to expect success if this is begrudged. Good soil should always be in store in some convenient out-of-the-way place, stacked in ridges; and the cribs in the potting sheds should always be full, that materials in a fit and proper condition for use may always be there when wanted.

## FRUIT WITHOUT FLOWERS.

At a meeting of the Academy of Natural Sciences, Philadelphia, February 11th, Dr. Ruschenberger, the president, in the chair, Mr. Thomas Meehan presented an Apple, which was borne by a tree at Kittaning, in Pennsylvania, and which tree never produced any flowers in the popular acceptance of the term; but always yielded an abundance of fruit. This specimen furnished a practical illustration of some morphological truth which could not often be demonstrated in the way this afforded the opportunity of doing. It was admitted that a fruit was a branch with its accessory leaves transformed. The Apple fruit was made up of a series of whorls of leaves comprising five each. Cutting an Apple through we found a series of five formed the carpels containing the seeds. Several series of whorls, very much retarded in development, probably formed the stamens, but this could not be so well seen in the Apple fruit, as they seemed to be almost absorbed in the corolla series. This was the next in order that appeared in the divided Apple—the green curved fibrous line which we find in all Apples midway between the “core” and the “rind” is the dividing line between the series which forms the corolla and the outer series which forms the calyx. In this tree there are no pistils, the series which usually goes to make up this part of the fruit structure being either very rudimentary or entirely wanting. Hence there was no core to the fruit. The result of this want of development was that the usual calyx basin of the Apple was in this case occupied by a cavity three-quarters of an inch across. There were no petals; but in place five gland or rather bud-scalelike processes, at regular distances, on the edge of the green fibrous outline before referred to. The outer whorl, which usually forms the calyx, was almost asepals, as a mere scarious membrane marked the place where the calyx segments or sepals should have appeared. It was so easy in this specimen to trace the dividing line between the outer or calycine whorl and the inner or corolline whorl, which, uniting and becoming succulent, formed the popular Apple fruit, that it was worthy of note in this connection. But the most interesting feature in this specimen was what were probably, from their similarity in appearance, cork cells, formed abundantly on the outside of the Apple. It would seem that, with the lack of development in the inner series of whorls necessary to the perfect fruit, those which remained were liable to take on somewhat the character of bark structure.

**Pears and the Frost.**—I find that the May frosts have played sad havoc with the Pear crop. Almost the whole of the outside fruits on pyramidal trees are bitten on their upper sides, and of course ruined. No simple protection of boughs has been of much use against May frosts driven into the tender fruit by the east wind. That wind seems as freely freighted with ice as if it were January; it (the wind) stays in the east with a persistency that is really heart-breaking to cultivators. While I write (June 2nd) it is there, straight as a needle to the pole. I doubt even if this bitter wind will not thin the Apple fruits. Latterly it has blistered some Peaches and Nectarines as if fire had passed over them. I observe, too, that Pelargoniums and Calceolarias, well hardened off, and perforce put out, are struck all down their eastern sides, as if fire had burnt or frost frozen them.—D. T. F.

**The Blood-leaved Peach.**—The *Gardener's Monthly* illustrates and describes this new ornamental foliaged Peach, the leaves of which, early in the year, are said to be of a deep blood-red colour, but to gradually fade as the weather becomes warmer, when they assume a dull green appearance. Its fruit is medium sized and slightly oblong, somewhat flattened; skin white, with a pale red wart, and a few pale red spots or stripes; flesh white, juicy, well flavoured; clingstone; ripens beginning to middle of August. It may be classed as good in flavour, but deficient in size. About Philadelphia it ripens in the end of September, and when making a second growth in August, the leaves are nearly as brilliant as in spring.

## NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Early Forced Grapes.**—A market gardener and early fruit grower in West Middlesex told me, on the 25th of May, that he had been cutting Muscat of Alexandria Grapes for a month previously, and that they fetched 2s. per lb. in the market. This fact will, I imagine, startle some of our gardeners, who, although they have great private resources to support them, are still beaten, in the matter of early Muscats, by our growers for market.—A. D.

**Standard Orchard Pears.**—In a recent number of the *Bulletin d'Arboriculture*, the following are recommended as the “best winter Pears to be grown as tall standards,” and therefore suitable for orchards:—Bergamotte Espéren, Bergamotte Hertrich, Beurré Luizet, Beurré Milet, Comte de Flandre, de Cœur, Doyenné d'Alençon, Doyenné Sieulle, Josephine de Malines, Marie Guisse, and Passe Colmar.

## THE CASCADE AT VIRGINIA WATER.

THE falling of water, whether in the roar of a mighty cataract, or the gently rippling murmur of a group of trickling falls, is so invariably pleasing, that travellers deviate miles from their route to catch but a glimpse of the beautiful phenomenon; and artists linger for weeks in the neighbourhood of a celebrated fall in order to study earnestly the ever-changing features of its aspect—the rising mist that often veils the lower portion in exquisite indistinctness, the fitful hues of the iris that in a passing gleam of sunshine appear and vanish in a moment; and the foam, churned into compact masses that are carried down the impetuous stream till they dissolve and blend again with the water.

These, and such as these, are the objects sought out for study by the painter. But the horticultural artist, in every new model which he becomes acquainted with, seeks to ascertain how far the features which he perceives, whether natural or artificial, can be utilised in works of his own. There

## THE INDOOR GARDEN.

## PHALÆNOPSIS GRANDIFLORA.

THERE are but few Orchids that rival the Phalænopsids in floral beauty. There is a regal stateliness in their habit of growth that proclaims them to be members of the aristocracy of the vegetable world. There is the gracefully-curved flower-stem and the precious weight of pearly blossoms borne at its apex. These are flowers fit to weave in the tresses of an empress on her bridal morn! The lustrous rubies and emeralds of her tiara could not vie with the chaste purity of those sculptured petals; priceless diamonds with borrowed lustre cannot eclipse the modest splendour of those snowy blossoms! Naturally Phalænopsids are epiphytes growing in Borneo, Java, Sumatra, and on the continent of India. In cultivation they require a warm humid temperature and moisture at the roots all the year round, though less is essential

View of the Cascade at Virginia Water.

are few illustrated works on gardening without several representations of cascades of various character—from the formal tumbling of the waters at St. Cloud and Versailles, to that style of more natural-looking cascades which are found in nature, and occasionally in well-designed gardens. Our illustration shows the waterfall at Virginia Water, and is a noteworthy example of good work in this way. It is a good representation of a very clever work of horticultural art. The manner in which a portion of the water is diverted from the main stream to trickle over the rocks below the fall in streaks of glistening silver is a very successful and effective device. It was, perhaps, suggested by the celebrated cascade of Tivoli; but it is none the worse for that, as it would doubtless be very difficult indeed to discover a more exquisite model of the kind.

H. N. H.

THE young Planes planted on the Thames Embankment are now out in fresh and beautiful leaf, and are evidently thriving vigorously.

during the dull winter months. Phalænopsids, if large, may be grown in pots, in crocks, in charcoal, and living sphagnum; small plants do well on blocks with a little sphagnum moss, or they may be grown in baskets in the above compost suspended near the glass and carefully shaded from bright sunshine. Nearly all the species are most profuse bloomers; indeed it is often necessary to cut the flower-spikes off small plants, or they would thoroughly succumb to this over-flowering propensity. *Phalænopsis grandiflora* and *P. Schilleriana* have been imported in large quantities recently, and plants may now be purchased for shillings where guineas were formerly demanded. No collection, however small, should now be without them. Both stand in the foremost rank in the genus to which they belong. The roots of *P. Schilleriana* are very distinct from those of the other species of this genus, being flat, and having a rough appearance. The leaves are beautifully marked with bands of white, and the blooms individually are very large and handsome.

F. W. B.

## THE PANSY AS A POT PLANT.

THERE is scarcely a flower show of any note at which prizes are not offered for collections of cut blooms of Pansies, and some schedules have classes for Pansies in pots; and there is reason to believe the cultivation of the Pansy in pots is gradually extending, not only for show purposes, but also because the profusion of richly-coloured flowers produced during the early spring months when grown in this way are so attractive. Some hints as to the best mode of growth in pots, therefore, cannot fail to be acceptable at the present time. The best plants for blooming in pots in early spring are those struck from cuttings in June and July. These will strike readily under a hand-glass, in a bed of light sandy soil, occupying a northern aspect, where the glare of the summer sun does not come, and where there is no drip from falling rain. As soon as these are sufficiently rooted, they should be placed in well-prepared beds, in a shady place in the open ground, and from these should be drawn the plants required for cultivation in pots. Early in October these should be put into large 60-pots, placed in a cold frame till established, and then placed in the open air as long as the weather is mild and open; a compost made up of well-decomposed turfy loam, rotten manure, some leaf-mould, and coarse sand, the latter in proportion to the close or free nature of the loam, as the case may be. About the last week in January, or by the first week in February, there should be a shift into the blooming pots of the size known as 32's. One of the most successful Pansy cultivators of the day, Mr. Charles Turner, of Slough, recommends, "when potting, to loosen the outside of the old ball, remove a portion of the top soil, and drain the pots, as you would for Carnations," with a layer of crocks about an inch in depth. "After covering the bottom of the pot with crocks, place some of the coarsest soil, mixed with a little manure, over the drainage, and shake all down by striking the pot on the bench. The soil should not be pressed hard with the hand; no water should be given for a day or two after potting." A common two or three light wooden frame is the best place in which to keep the plants during the winter; but it should be shallow rather than deep, so that the plants may be not too far from the glass. Air should be given freely on all occasions when the weather is mild; in severe frosty weather the plants should have the protection of some mats. The plants selected for pot culture should have a bushy branching growth, and consist of four or six leading shoots if a good head of bloom be required. To impart all possible strength to these, the side-shoots springing up from the base of the plant should be removed, and inserted as cuttings. There is, therefore, the double advantage of strengthening the main shoots by their removal, and the production of a supply of young plants to take the place of the old ones when worn out. The exhibitor of Pansies in pots should always have a supply of plants, so as to ensure a good succession of bloom.

As the shoots make growth they should be tied to stakes, and, in the case of plants wanted for late blooming, the main shoots can be pinched back, so as to ensure plenty of side growth. These will not bear such fine flowers as the plants carrying only three or four main shoots; but a larger quantity of bloom will result, and they will prove charming decorative objects. Plenty of air must be given, to keep the plants from becoming drawn. The cultivator should aim at a short, sturdy, healthy growth, and as the flowers open they should be screened from the sun. Strong-growing varieties, bearing large flowers, should always be selected for cultivation in pots. Some liquid manure should be given as the flowers expand, but the plants should be so raised that it can drain away freely. Plants so treated will produce finer blooms than those obtained from plants growing in the open ground, and they are not so liable to the many accidents that beset flowers grown where little protection can be afforded them. A cultivator, by growing a few plants in pots, can have fine heads of bloom under cover early in the season, and the cuttings made from the side shoots taken at this stage will furnish him with plenty of young, vigorous plants to bloom in beds in the open air in autumn, where, in the cool, moist, declining days, well-developed flowers can be had. It is during the temperate days of spring and the cool days of autumn that the finest Pansy blooms are produced; hot weather is against them at all times.

for the lacing or belting to the flowers never comes so perfect, nor is characterised by such fine hues when grown in bright, dry, summer weather. The grower need scarcely be reminded that during the time the plants are making their growth they must be kept free from greenfly, and an occasional fumigation with tobacco smoke will secure this. Some of the best flowers of later years have come to us from Scotland. The climatic conditions of that country are more favourable to the culture of the Pansy than the drier atmosphere of the southern parts of England. Messrs. Dickson and Co., and Messrs. Downie, Laird, and Laing, of Edinburgh, Messrs. White and Sinclair, of Paisley, and others, are constantly producing new varieties, which are divided into three sections: Selfs, yellow ground, and white ground flowers. Of yellow selfs, Cherub, Mrs. Horsburgh, and Pophirie; of white selfs, Great Eastern, Miss Ramsey, and Peerless; of dark selfs, Eclat, George Keith, L. T. Fleming, Luna, and Miss Muir are the best. Of yellow-ground flowers there are Comus, Ebor, George Ford, George Wilson, George Muirhead, John Currie, O. C. Champion, Robert Burns, Tom White, and William Young, all of fine quality, and more or less distinct in character; and of white grounds, Alice Downie, Cupid, Jane Wilson, Lady Lucy Dundas, Miss Addison, Miss Adamson, Mabel, Princess of Wales, Village Maid, and Waverley—all very beautiful, and showing many hues of colour.

Quo.

## PLANT GROWING FOR MARKET.

EVERYONE who has seen the fresh, sturdy, little plants brought by the market growers round London to the Metropolitan markets will readily acknowledge that there is much skill shown in their cultivation. Market growers have not, however, always convenience for doing things well; on the contrary, they often labour under especial disadvantages. As regards second and third class material, our markets are somewhat overstocked, but really early, well grown plants may always be disposed of at high prices. While I write I am within a stone's throw of several little places where an astounding quantity of market plants is grown. On entering one of these establishments the other day, I was struck with the great heaps of fresh, sweet, fibrous loam, leaf-mould, and cow-dung that confronted me. The best growers are very particular as to their compost heaps, and go to great expense in procuring the best loam they can find. In growing for market, good soil, light span-roofed houses, and brick or turf pits, together with an abundant supply of water, are the great essentials, to which must be added energy and forethought. The plants principally grown for market purposes are Fuchsias, Pelargoniums, Heliotropes, Hydrangeas, Richardias, Stocks, Asters, Mignonette, Pinks, Cloves, Carnations, Lily of the Valley, Spiraea japonica, Roses, bulbs, and numerous plants and shrubs suitable for spring forcing. Plants for market should be dwarf, bushy, and profusely flowered, say from 6 to 18 inches high. Cyclamens are generally grown from seed sown in the autumn, or as soon as it is ripe, and the young plants are pushed on rapidly during the ensuing summer, and flower profusely the following spring. Many half-hardy annuals, as Rhodanthe, Nemophila, Balsams, Celosia, and ornamental Grasses are grown beautifully by some cultivators with hardly any appliances except turf pits. Fine-leaved plants, as Ficus clastica, Isolepis gracilis, Selaginella hortensis, and some of the hardier exotic and British Ferns are grown by the thousand, and are readily sold at remunerative prices. A subject of great importance in plant culture from a decorative point of view, viz., careful selection of varieties, is zealously attended to by market growers, and in selecting seed parents they always give preference to robust plants of dwarf, compact habit, good constitution, and free-flowering qualities. Primulas, Calceolarias, and Cinerarias are remarkably well grown by some cultivators in low span-roofed houses or pits, and the "strains" which some of these market people possess are superb, the flowers being large and of good colour and substance. Most of the growers select seed-bearing plants, and carefully hybridise them when necessary, in order to obtain a good strain, and some are so particular that on no account would they part with a single seed of their own saving; others, on the contrary, sell their strains to the seedsmen. When we consider that Primula seed fetches from £10 to £20 per oz., we need not wonder that five shilling packets should contain such microscopic quantities. Hydrangeas are just now coming into the market, and very fine some of them are, with great heads of flowers nearly a foot across. One cultivator at Acton grows these by the thousand, and does them better than anyone else with whom I am acquainted. Some of the individual blooms measure more than 2 inches across, and are most beautifully coloured by exposure near the glass. The same grower

has one of the finest beds of Lord Lyons Pink I ever saw, from which thousands of bright crimson-purple flowers may be cut. A white flowered Pink of large size and good substance is Alba multiflora, the blooms of which are as white as snow, and measure nearly 3 inches across. Though somewhat delicate in constitution, it bears forcing well. The prices realised for different plants depend on their quality and earliness. Zonal Pelargoniums fetch from 9s. to 18s. per dozen; Hydrangeas, such as I have described, 21s. to 30s.; Fuchsias 12s. to 21s.; and other things in proportion; after which the retail dealers make, in many cases, a handsome profit. Some growers for market have a great variety of decorative plants, but most of them confine themselves to a few really good things, and grow these by the thousand. The work in one of these establishments appears to be one unceasing routine of propagating, potting, watering, tying, and packing off to market; and in a well regulated place it is rare to find a spare inch of room or a frame unoccupied, for as fast as the plants in flower are sold, succession plants are potted on to fill their places. B.

LATH BLINDS FOR SHADING.

In paying a visit to the Belgian nurseries lately, I was much struck with the very convenient sun-shades employed to cover houses and frames in that country. We all know how soon blinds of linen and

Shade of small Laths and slender Rods united by twine; full size.

cotton become tender and worthless. The Belgians employ thin laths of wood laid side by side, with narrow intervals between them, in the way of Venetian blinds; cords laid across them, to which the laths are attached by tarred string, connect all together. These

Shade for frames.

blinds, which look like the Roman fascies, can be made of any length and of any convenient width, and are rolled up with great ease. In one nursery I saw split bamboo used for this purpose, which no doubt is lighter, stronger, and still more durable than strips of ordinary wood. If these blinds could be had in England, I think there

Shade of very slender Rods of wood and twine; full size.

would be a demand for them. In Belgium, I imagine, they are made by the gardeners in winter; but I neglected to make the inquiry.

Chilwell. J. R. PEARSON.

[Should any of our readers desire to know how the shades of which Mr. Pearson speaks are constructed, we shall be happy to show them some very neat models which we brought home some time since from the continent, and which are now open to inspection at THE GARDEN office.—Ed.]

MARSHAL NIEL ROSE UNDER GLASS.

BEAUTIFUL, no doubt, are the golden blooms of that noble yellow Rose, Marshal Niel, even when seen displaying their beauties but sparsely and shyly, as is generally the case when grown in the open air. It is, however, when seen growing under glass, and dropping its golden pendants from the roof, not in threes, or in dozens, but in numbers which defy counting, that one realises its flowering capabilities and becomes impressed with the conviction that it is when grown well up to the light as a conservatory climber that the Marshal is in its right place, and in the field in which to win new Laurels. Of this we were more convinced as we lately gazed with admiration on the very remarkable specimen of this lovely Rose, which, when in the full display of its floral honours, is the pride of the Belfast Botanic Garden, and of the curator, Mr. Johnston. A few particulars with regard to the Belfast plant will, we trust, not be without interest, and may perhaps be of some practical value to our Rose loving and Rose growing readers. Some four to five years since, when the Rose was much scarcer and its fame less widely established than it now is, Mr. Johnston was given a by no means particularly vigorous or robust plant of the Marshal. Unwilling to expose it to the open air, he assigned it a modest corner next the front wall of one of the wings of the large conservatory. Here with sods he formed a raised bed for its reception, some two or three feet square, and about so much in depth, and into this he transferred the plant. The Marshal took kindly to his new quarters, and the first year favoured his patron with the modest number of just half a dozen blooms. When, the year before last, the garden was honoured with a visit by the Lord Lieutenant and Countess Spencer, the plant carried some six hundred flowers, and her excellency was presented with a splendid bouquet entirely composed of magnificent blooms culled from among them. Last year the number was largely increased, and this year, when we saw it, we were informed it had borne over 1,500 superb blooms! Inducing it to make plenty of wood, and then having it thoroughly ripened, are the elements of success as regards the Marshal, and on any one securing them he is sure to shed in profuse bounty his golden favours. What about pruning? we asked Mr. Johnston; "Except to cut the flowers, a knife never touches it," was the reply.—*Irish Farmers' Gazette.*

*Aerides crassifolium.*—A robust and well-grown specimen of this rare species has at last been flowered by Mr. Whitehead, gardener to F. B. Dodgeson, Esq., of Blackburn, Lancashire. It has been called "the best species in the genus," which is saying a great deal, considering we have the noble *A. Fieldingi* and the still more handsome and rare *A. Schröderi*. This new species is one of Messrs. Low's importations, and is easily distinguished, even when not in flower, by its broad, thick leaves, and dense habit. Its flowers call to mind those of *A. (falcatum) Larpentæ*, being similar in conformation, but they are produced on a much longer drooping spike. Their colour is also much deeper and more effective than that of the last-named species, being a soft, clear amethyst purple, shading off into white at the base of the segments. The peculiar tint belonging to this species is similar to that found in the petals of *Phalæopsis Luddemanniana*, but deeper and richer in tone. Mr. Dodgeson's plant has ten leaves, which vary from 5 to 9 inches in length, and are about 2 inches broad, the younger leaves being dotted with purple and slightly tinged with brown. It has borne twenty fine flowers on a spike, and this number will doubtless be exceeded as the plant develops itself. This *Aerides*, as has just been stated, is as yet very rare, but now that its charms are recognised by cultivators as being something superior to those of others, it will doubtless soon find its way into the most select collections.—F. W. B.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

*Cantua dependens.*—At Eilton House, near Grantham, one of the pillars supporting the roof of the lofty conservatory was a few weeks ago a perfect picture of floral beauty with the above plant, which was full of bloom from the base to a height of 20 feet at least. The flowers in colour can only be described as a scarlet crimson cerise, and occurring in thousands, their beauty may be imagined by those who have only seen, as is usually the case, a few flowers on a sickly "red spider" plant. Here of course it is planted in a border, and is hence greatly relieved from liability to attacks from insect life.—J. C. N.

*Mahernia vestita.*—This little plant is seldom seen, but I do not think that, for amateurs especially, a finer flowering one could be found. It is a native of the Cape of Good Hope, will thrive in any house in which the temperature is kept above the freezing point, and succeeds perfectly in a compost of good loam, mixed with a little peat or leaf-soil. It requires to be repotted annually, but overpotting is injurious to it, and must be avoided. It likes plenty of water whilst growing, but no stimulants; and it should be pruned in a little after it has done flowering. Thus treated it becomes covered in May or June with a profusion of little orange and red flaked flowers that are at once graceful and ornamental.—JAMES FORBES, Perth.

## INSECT AGENCY IN FLOWERS.

BY THOMAS MEEHAN.

I AM of opinion that art has not so much to do with garden variations as is generally supposed; that variations in nature are as great as in horticulture; and that the florist's credit is chiefly due in preserving the form which unassisted nature has provided for him. It was at one time part of the essential idea of a species that it would reproduce itself. If any variation occurred in nature, it was taken for granted that seedlings from this variation would revert to the parent form. But it is now known that the most marked peculiarity in variation can be reproduced in the progeny, if care be taken to provide against fertilisation by another form. Thus, the blood-leaved variety of the English Beech will produce blood-leaved Beeches; and, as I have myself found by experiment, the very pendulous Peach produces from seed plants as fully weeping as its parent; and when the double-blossomed Peaches bear fruit, as they sometimes do, I have it on the authority of a careful friend that the progeny is double-blossomed as its parent was. But I need not refer particularly to this. Any intelligent florist of the present age can testify to the fact, that varieties will reproduce themselves as fully as the original forms from whence they sprang. I do not think botanists, as such, are so fully aware of these facts as florists are. They scarcely admit of much inherent variation in form in nature; but look rather to hybridisation, and insect agency in connection therewith, to account for such changes when they occur. In order to avoid the possibility of these agencies acting as the sole factors in evolution, I have generally taken a genus consisting of only one species in a given locality, to show how great is the variation in form, where no congenial species could mix with it. I have, for this, chosen *Epigæa repens*, *Chrysanthemum leucanthemum*, and the *Quercus neo-mexicana* (Q. *Gunnisonii*?) of the Rocky Mountains. Another familiar plant to illustrate this is the common yellow toad Flax (*Linaria vulgaris*). In a handful of specimens gathered in an afternoon's walk, I have found some marked variations, differing from each other almost as much as species do. In regard to the spur, which is generally as long as the main portion of the corolla, some had them only one-third or one-fourth as long; and in one instance the plant bore flowers entirely spurless. Dr. Darrach informs me that he believes he has, in years past, gathered a spurless form, but has neglected to place it on record. Then some plants had flowers with spurs thick, and others with narrow ones; and while some had spurs quite straight, others curved so as to describe nearly the half of a circle.

Now this *Linaria* is an introduced weed, with nothing allied to it anywhere, in the localities where we usually find it, with which it can possibly hybridize. The variations must be from some natural law of evolution inherent in the plant itself. Varieties of course may cross-fertilise as well as species; and some of these variations may be owing to one form fertilising another form; but there can be no avoiding the fact, that at least the first pair of varying forms must have originated by simple evolution. Now, going back to our florists' experience, the question occurs, that as varieties once evolved will reproduce themselves from seed, why does not some one of these *Linarias*, which has been struck off into some distinct mould, reproduce itself from seed, and establish, in a state of nature, a new race, as it would do under the florist's care? Why, for instance, is there not a spurless race? It is scarcely probable that the solitary plant, found on this afternoon's walk, is the only one ever produced. Dr. Darrach's recollection shows it is not a solitary case. The humblebee furnishes the answer. They, so far as I have been able to see, are the only insects which visit these flowers. They seem very fond of them, and enter regularly at the mouth, and stretch down deep into the spur for the sweets gathered there. The pollen is collected on the thorax, and of course is carried to the next flower. The florist, to "fix" the form, carefully isolates the plant; but in the wild state a spurless form has no chance, the bee from the neighbouring flower of course fertilising it with the pollen from any of the other forms. If there were no bees, no agency whatever for cross fertilisation, nothing but the plant's own pollen to depend on, there would undoubtedly be races of this *Linaria*, which, again, by natural evolution at times changing, would produce other races; and in time the difference might be as great as to be even thought generic. But we see that by the agency of the humblebee the progress of the newly evolved form is checked. The pollen of the original form is again introduced to the offspring, and it is brought back at least half a degree to its starting point. Insects, in their fertilising agencies, are not always abettors, but rather at times conservators of advancing evolution.

A LADY having the misfortune to have her husband hang himself on an Apple tree, the wife of a neighbour immediately came to beg a branch of that tree, to have it grafted into one in her orchard. "For who knows," said she, "but it may bear the same kind of fruit."

## THE COCOA-NUT PALM.

(COCOS NUCIFERA.)

THIS is now so extensively cultivated throughout the tropics that it is impossible to ascertain its native country; there can be no doubt, however, that it is indigenous to some part of Asia, probably Southern India. It exists in vast quantities on the Malabar and Coromandel coasts, and the adjacent islands, growing in the greatest luxuriance upon sandy or rocky seashores. It is also common in Africa, South America, and the West Indies. The Cocoa-nut Palm has a cylindrical trunk, sometimes as much as 2 feet in diameter, and rising to the height of 60 or 100 feet, surmounted by a crown of gracefully curved feathery or pinnate leaves, each of which is from 18 to 20 feet in length, and composed of a strong tough central footstalk, with numerous narrow, long, and sharp-pointed leaflets arranged along both sides of it, giving the entire leaf the appearance of a gigantic feather.

The uses of the Cocoa-nut Palm to the dark children of the tropics are manifold, forming, as it does, both food and shelter, as well as fibre, that is employed for a vast number of purposes. In no country with which I am acquainted have I seen it so extensively cultivated as it is in Ceylon, and none but those who have travelled the glorious Government road from Point de Galle to Colombo, one of the loveliest of drives, seventy-two miles in length, and varied only at long distances by a few gentle undulations, can have any idea of the beauty of a Cocoa-nut plantation. This drive passes through a belt of Cocoa-nut forest, varying in depth from one to six miles, until it approaches Colombo, where you have Cinnamon plantations on the one hand, and the Cocoa-nut Palm on the other, dipping so near to the sea as to be often washed by the surf, as the waves swell and break along the shore. Cocoa-nut cultivation is chiefly confined to the native population, and is, with the addition of a patch of "Paddy Rice land," a few Gourds, and other tropical vegetables, such as Chillies, Cucumbers, Yams, the roots of the *Caladium esculentum*, the fruit of the Jack tree (*Artocarpus integrifolia*), the Bread Fruit tree (*Artocarpus incisa*), and a few other wild productions of the land, the whole source of existence of the poorer classes in Ceylon. Sometimes wealthy Ceylonese own large plantations of Cocoa-nuts two or three hundred acres in extent, but more generally they are confined to small patches, which are distributed among the villagers; and such is the importance attached to this "King of Palms" that one often hears of a lawsuit having taken place, to recover the tenth share of a Cocoa-nut tree! There are also large plantations owned by European merchants and planters. In making a Cocoa-nut plantation, it is necessary, in the first instance, to form a well-stocked nursery, in order to prevent the incursions of porcupines, and other animals, that love to prey on the succulent shoots of the young plants as they first make their appearance above-ground, and to protect them till the first fronds have matured a sufficiency of fibre to resist the onslaughts of their enemies. They are then moved to open plantations prepared for them by cutting down jungle timber and brushwood, the worthless portions of which are burnt on the land, holes being cut for the reception of the Cocoa-nut plants from 15 to 20 feet apart, about 4 feet square, and 2 feet in depth. After being planted, young Cocoa-nuts require seven years before they come into bearing; and, unless they have been placed in good soil, or have received some extra cultivation, they do not produce very heavy crops during the first few years of fruiting. As soon as the young Cocoa-nut trees are strong enough, cattle are allowed to graze freely amongst them; and, being penned up at night on different portions of the plantation, as on our own system of winter and spring sheep-feeding, the crops are thereby materially increased. Each Cocoa-nut Palm produces annually from twelve to twenty-five nuts; and each nut being incased in a heavy conical husk, the trees have a heavy load to carry, as each nut weighs from 4 lbs. to 5 lbs. Rarely does a year pass in Ceylon that some half-dozen deaths are not reported from ripe Cocoa-nuts falling on the heads of some of the villagers.

The modes by which Cocoa-nuts are gathered are various; sometimes, as shown in the accompanying illustration, ladders are placed against the trees to a certain height, to facilitate

the climbing, after which a rope is looped both round the stem of the tree and the body of the climber, who, setting the soles of his feet against the stem, and holding on by his hands, his body forming a curve supported by the looped rope, ascends the tree very much as a monkey does his pole; in fact, such is the agility of some native nut-gatherers, that I have seen them ascend without ropes or other assistance.

mills belonging to Europeans, where they are broken up and divested of their shells, the kernels being thrown into heaps to ferment, previous to being put into the mill and ground up, after which the oil is expressed by hydraulic pressure. The refuse of the nut, after the oil has been expressed, is formed into oil cake, which in Ceylon bears the name of Poonac. The bullock carts used for the transport of Coffee and Cocoa-nut

Group of Cocoa-nut Palms.

In extensive plantations, the trees are fastened together by means of stout ropes, over which the harvesters pass from tree to tree without descending, thereby saving both time and labour. As soon as the nuts are harvested, they are divested of their outer coverings, which are stacked for future use. The nuts are then conveyed either to the native oil mills, which are worked by oxen, or to the more powerful steam

oil are thatched with Cocoa-nut leaves, which make them impervious to the heaviest of tropical showers. Cocoa-nut leaves are also used for thatching the roofs of the native huts and for shading verandahs. As nearly as I can remember, Ceylon exported about 20,000 tons of oil annually, all the time I was there, and about 5,000 tons of fibre and yarn, known as Coir. Coir-mat making affords employment to the low-

country Cingalese, who manufacture them of various patterns and forms.

But not only is the Cocoa-nut valuable on account of its commercial productions. To the natives, as I have already mentioned, it forms a principal ingredient of their daily diet. No curry would be perfect without some finely scraped Cocoa-nut—no salad palatable unless dashed with some of the milk of the ripe nut; and one of the greatest of luxuries is the delicious milk of the Cocoa-nut when about three-parts ripe. Only those who have travelled hot tropical roads, through countries where water is so bad that the very look of it is repulsive, can form any idea of the value of a drink from a cool Cocoa-nut.

PETER WALLACE.

## THE FLOWER GARDEN.

### THE CRIMSON DESERT PEA.

(CLIANTHUS PUNICEUS.)

If this beautiful wall plant were better known it would require no commendation from me to induce its wider cultivation. It is perfectly hardy, except probably in very cold and late situations. Even in unfavourable climates it may be preserved by a mat or other such slight protection; and in favourable circumstances it is a magnificent object. I have only seen, in the many gardens I have visited this year, two specimens in the open air. The first is in Mr. McDonall's nursery at Stranraer, in which a south wall was aglow with the bright clusters of flowers to the height of 9 feet, and the width of perhaps 12 feet; I was informed that it had been in constant flower since February. The other specimen was on an east wall in Mr. Fitzherbert's garden at Blackcastle, near Navan, and, though not so large a plant, still it was very healthy and flowering profusely. Young plants should be obtained now in pots and planted out at once. They should be kept regularly supplied with water in summer, and as dry as possible in winter, and when thoroughly established will respond freely to generous doses of manure-water.

SALMONICEPS.

### BLUE-FLOWERED BORDER PLANTS.

I INTEND to say a few words on *Gentiana acanlis*—not to eulogise it, which is unnecessary—but to point out how it appears to suffer when placed close to two very beautiful plants which I have in my little garden. The first of these is the blue flowered *Dracocephalum grandiflorum*, a tolerable large mass of which seems even more beautiful than the *Gentiana* itself; but perhaps that may arise from the comparative rarity of the *Dracocephalum*. Why is this fine *Dracocephalum* so seldom seen? It is of the easiest possible culture. To flower it well, it should be pulled to pieces now and then, and the strongest pieces planted from six to twelve in a clump; it likes a rather stiff soil. The next plant that appears to rival or eclipse the *Gentiana* is the truly beautiful *Lithospermum prostratum*. Nothing can surpass in brilliancy a large mass of this when seen under the full blaze of the mid-day sun, on a gravelly bank or rock-work. Like the *Gentiana*, it seems to do best when starved. The best way to flower the *Gentiana*, as a border plant, is to place about a hatful of stones in a small mound, and plant bits of *Gentiana* over them. These little mounds show the plant off to advantage, and it prefers stones to soil. The one fault of the *Gentiana* is that it is rather fastidious in opening its blooms, which are always shut during dull or cloudy weather. I know a fine moated hall in Lancashire which was famous for its *Gentiana*. A gravelly bank on either side of the coach road, for perhaps 60 yards, right up to a bridge over the moat, was one mass of *Gentiana*, and parties came long distances to see it. Mr. Fish is hardly correct in calling the *Gentiana* azure; it is, I should say, intense ultramarine. I have a variety of it with each of the segments of the corolla tipped with white. This I have not seen elsewhere; but I have somewhere seen a pure white variety of *Gentiana*.

THOS. WILLIAMS.

### PRIMULA CORTUSOIDES AMENA.

NOTWITHSTANDING all that has been said in favour of *Primula japonica*, I am inclined to think that the beautiful *P. cortusoides amena* is in reality the queen of Primroses. By the way, according to professor Morren, it is no longer *Primula cortusoides*, but *Primula Sieboldi*. I think, however, that lovers of this flower will elect to stand by the old name. This beautiful Primrose has now been in cultivation for some time past; but it is not half so much appre-

ciated as it deserves to be, for the simple reason that it is not widely known. *P. japonica* has turned out a somewhat disappointing introduction; and never once, since it has been cultivated, has it realised the character depicted in the coloured illustration of it with which lovers of flowers are familiar. On the other hand, *P. cortusoides amena* has more than realised what was predicted concerning it; and just in proportion as *P. japonica* declines in popular estimation will its congener as surely rise in favour. It is a very hardy Primrose, and one of the brightest bits of colouring I have seen this season was a clump of this Primrose growing in the open air on the herbaceous border at Chiswick. This plant had been out all the winter, and, notwithstanding the incessant rainfall, no injury had befallen it in consequence. The beautiful bright roseate hue of the flowers struck the eye when looking at them, even from the most remote points of view. This Primrose should have a good position, fully open, and a little high, if possible, and it should be planted in some good rich soil. It is a fine subject for a sheltered rock garden; but in any case, when it gets well established, it blooms with freedom. It makes a fine pot-plant also, and, when thoroughly established in 32 or large 48-sized pots, it produces several trusses of beautiful flowers. About August the plants should be divided, but not too freely, and potted in a soil made up of good loam, some sand, and plenty of leaf-mould; and then the plants should be put into a cold frame or cool house, and be kept close and shaded till established. They will simply need protection from rough weather. The strongest will flower in April, or earlier, and during May.

R. D.

Bitton Long Ago.—I am the old gardener of Bitton, and I have just been gratified by your report of what you saw there at Easter. All the trees there, excepting the two Yews, and those only 20 years old, were planted by my own hands. I don't think there can be a more favourable soil, deep loam on a bed of gravel. My son has added greatly to the collection. It was about 1830 when I had full 3,000 different plants, all in open borders—all the *Pæonies* and *Sedums*, over 100 *Asters*, and as many *Irises*, 30 *Yuccas*, *Chrysanthemums*, *Narcissus* over 100, all the *Crocuses*, 30 water plants, and a *Rosarium*. There were, moreover, *Ferns*, and that at a time when a London nurseryman laughed at me for inquiring for such plants in London. I had all the *Irises* which I could get, being then in correspondence with the Paris Garden and the Berlin Garden. This is a wretched soil, and most discouraging, and I am too old for working as I did at Bitton, and my old gardening friends and nurserymen who knew me are all dead. My old catalogues—which my son has—will prove what was grown at Bitton. I never cared for florist flowers. You ought to have seen the single scarlet *Anemone* in great perfection. Bitton was rich in *Saxifragas* and *Veronias*. My son has more rarities than I had, and recent novelties. I thought these few notes would interest you. I could not grow the double blue *Hepatica* at Bitton, and here it flourishes, but I managed *Cistus* and *Helianthemums* well.—H. T. ELLACOMBE, *Clyst St. George, Topsham*.

### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

*Aquilegia cærulea*.—This is flowering splendidly here. It delights in rich turfy loam. The border must be well drained, as damp often proves fatal to this fine plant during the winter months.—J. WHITTAKER, *Derby*.

Autumn-blooming *Crocuses*.—We generally associate *Crocuses* with the spring. The Rev. Mr. Ellacombe reminded us the other day, that of the forty-three species mentioned in Dean Herbert's monograph of the *Crocus*, twenty-eight are autumn bloomers.

*Dodecatheon integrifolium*.—This has been one of the brightest gems in my garden during the past month. On one plant I have counted thirty-six flower-stems, with from sixteen to eighteen expanded flowers and buds on the stronger stems. It delights in rich peaty loam in a shady, sheltered situation.—J. WHITTAKER.

Top Dressing for *Roses*.—I am anxious to know if the malt or kiln-dust recommended by Mr. Rivers to be used as a top-dressing for *Roses* is the same as malt comings.—R. E. [The kiln dust used by Mr. Rivers is what accumulates behind the furnace, not comings which come from the malt when it is screened. Mr. Rivers uses one-half kiln dust and one-half horse-droppings, laid about 1 foot thick, then saturated with liquid manure, then turned over in the sun twice in about three days, when it may be used with good results on both *Roses* (pot or planted out) and fruit trees in pots.]

*Yucca baccata*.—This new and very distinct species, found in New Mexico, Utah, and Arizona, was introduced into cultivation in Europe last year by M. Linden, of Brussels. In the rigidity of its habit and the texture of its leaves, it bears a greater resemblance to *Y. cornuta*, or *Y. Trencleana*, than to any species of the *aloifolia* section. It has a thick, wrinkled stem, about a foot high, on the summit of which are closely crowded the short, straight, erect, pointed, boat-shaped leaves of a light green colour, bearing on their margins numerous long, broadish, and sharply pointed shaving-like appendages. The fruit is a capsule, as in all the *Yuccas*, but has the shape and fleshy consistence of a ripe Banana, by which name it is known to the natives of Western America. The taste is sweet and agreeable, and the Indians, who are very fond of it, gather and dry large quantities for winter use. The uncooked fruit is said to possess highly cathartic properties.—M.

GARDEN STRUCTURES.

THE ALEXANDRA PROMENADE.

Among the garden structures shown at the Alexandra Palace on the opening day (May 24th), the conservatory of which the annexed engraving is a representation, was not the least remarkable. Erected on the main plateau at the south-western corner of the terrace, though necessarily dwarfed by the size of the Palace, it occupied a position admirably suited to display its distinguishing features to advantage. Being constructed entirely of iron, glass, and hydraulic cement concrete, and glazed with sheets of large size, it had a light and airy, rather than a substantial, appearance, but examined from a structural point of view its strength was found to be ample. The side columns, placed six feet apart, are of cast iron twisted, with a moulded base, and each is strutted by an ornamental buttress resting on a block of concrete. From these, the T iron rafters, bent to the desired form, spring and form the roof. Between the columns, meeting at the centre of each bay, are carved spandrels of elaborate tracery; and the walls are of hydraulic cement concrete slabs, moulded and manufactured under Mr Ayres' patent. These admit of a large amount of ornamentation, with this advantage, that not being attached to the soil they are tenants' fixtures in the fullest sense of the term. The shelving or stages for the plants are also formed of the same material, panelled to hold water for evaporation, and perforated for the warmed air from the source of heat to pass through them among the plants. The doors are gothic in shape, with a tracery spandrel over head, and there are graduated ornamental pendants from each angle of the rafters, and a cornice of perforated iron work

The Alexandra Promenade.

THE KITCHEN GARDEN.

DEEP CULTIVATION.

THE question of more deeply disturbing and manuring the soil and subsoil is too important to be treated with levity or flippancy, for it greatly affects the amount of production of human and animal food. The opponents to deep cultivation say the plant multiplies its fibres or roots in the surface soil; of course it does, and why does it do so? because the surface soil is cultivated, loosened, manured, aerated, and, moreover, much warmer than the lower soil. It is, therefore, unmistakably evident that these conditions should be, as much as possible, imparted to the subsoil, where they are wanting; for when undisturbed and unmanured it is too dense, too cold, and too poor, and therefore too unattractive to the roots of plants, for the latter have as great an instinct as the animal tribe as regards their search for food. Many people won't believe that we cannot manure the under soil through the top soil, but that profound departed philosopher, Baron Liebig, proved this, therefore it becomes necessary to uncover the subsoil and intermix the manure with it. How well that late worthy and most intelligent man, the Rev. Mr. Smith, of Lois Weeden, understood and practised this system, and, as a consequence, what extraordinary crops he grew, as I know by personal observation. I have abundant experience in that matter on my own farm and in my own garden and shrubbery, and facts justify my insisting upon the importance and advantage of disturbing and manuring the subsoil, but not to attempt to do so through the top soil, for the top soil has the power to intercept and appropriate all, or nearly all, the ammonia, potash, and phosphate of lime that you have intended for the lower soil. In my conservatory I bore holes to the depth of 2 to 3 feet with an iron or stick, and down these holes pour guano and water, or liquid manure, and the consequence is an immense development of flowers on my Camellias. No such results occurred when the fluid was merely applied to the sur-

A Curvilinear Vinery without bent glass.

runs round the inside of the house at the level of the spouting, forming a suitable finish. For ventilation, sashes open the entire length of the house just above the wall slabs on each side, and there are also similar continuous sashes in the lantern all opening simultaneously by means of ingenious machinery. The roof is glazed with Hartley's rolled plate glass in large sheets, held in position by Mr. Ayres' recently patented glazing tube. This may be made of sheet copper or zinc, and though of great strength, is sufficiently elastic and compressible to yield to the expansion of the glass.

E. A.

face, for then its material ingredients never reached the lower roots. Some years ago, when I kept many pigs (350), I ploughed and then forked the poor and raw subsoil, throwing it into high ridges. Deep in the furrows I applied the pig manure, and forked it into the subsoil. The consequence was 43 tons of Mangel Wurzel per acre, and excellent crops ever since. On another field well subsoiled, but less deeply cultivated and manured, I only grew 30 tons per acre; but so numerous are the evidences of the increased produce resulting from soils with subsoils deeply fertilised by nature or by man, that it is quite unnecessary to say another word about it.—J. J. Mechi, Tiptree.

WORK FOR THE WEEK.  
PRIVATE GARDENS.

**Flower Garden.**—The planting out of summer bedding plants should now be finished as speedily as possible. Sub-tropical plants, such as *Cycas revoluta*, Palms, Musas, and similar material, should also be transferred to their outdoor quarters, giving them positions in which their beauty will be set off to most advantage; yet they must be sheltered, and not too confined with surrounding vegetation. *Monstera deliciosa* does well in a warm place under the shade of trees, and forms a good companion to tender Ferns, which may also be accommodated there. Plants of the green and also of the variegated leaved New Zealand Flax look well planted out, or plunged as centres to small flower beds, or used as specimens for conspicuous places, such as vases on terraces. American Aloes and Yuccas may likewise be used in the same way. Rose budding may now be commenced as soon as convenient; remove a goodly portion of the straggling wood, but preserve almost intact the shoots on which the buds are to be inserted. Propagate herbaceous plants by means of cuttings inserted in a prepared piece of border under hand-glasses. Transplant biennials from last spring's sowings, but if they have not yet been sown sow them at once.

**Conservatories.**—Passifloras, Bignonias, Kennedyas, *Hibbertia dentata*, *Lonicera sempervirens*, and similar plants, must now be regularly thinned, taking care to preserve as large a quantity of young wood as possible, without overcrowding, and permitting the shoots, after they reach a certain height, to hang down in graceful festoons. Keep up a good succession of flowering plants from greenhouses and frames, to replace those going out of flower.

**Greenhouses.**—These being now clear of bedding plants, may be filled with annuals, Pelargoniums, Fuchsias, Hydrangeas, Begonias, &c., in order to forward them for the decoration of the conservatory. Hydrangeas are now coming nicely into bloom, and require some assistance in the way of manure water; any shoots not furnished with flower buds should be removed, and used for purposes of propagation. By means of plenty of ventilation, complete exposure in fact during fine weather, retard the show Pelargoniums; zonal kinds for late flowering may now be cut over, partially starved for a while, kept out of doors, and if repotted and started into growth six or seven weeks hence they will form nice flowering plants when others begin to lose their beauty. Pinch, thin, and encourage Fuchsias, and keep *Celosias*, *Coleuses*, *Iresines*, &c., in a growing condition. Maintain successions of *Mignonette*, *Asters*, *Stoeks*, *Schizanthuses*, and other annuals. Old roots of *Cyclamens* not bearing seed pods may be transferred to a frame having a north and shady aspect, and kept moderately but not entirely dry. The young ones must be kept in a good growing state. *Liliums* should be top-dressed, and kept in cool or warm houses, according to the time when they are required to come into flower. Plants of *Spiraea japonica* that have done flowering should be transplanted into a plot of ground that is rich, moist, and warm. Sow *Cineraria* seeds and prick off seedlings, which, when they are fit to handle, should be potted separately into small pots. Suckers from the old plants should be potted as soon as they are large enough, and afterwards kept in a frame having a north aspect. Mark some of the very finest of the herbaceous *Calceolarias* for keeping until next year, and such plants as are selected to bear seed should be placed near the glass, and others removed as they begin to fade.

**Stoves.**—Fine-leaved plants now form a chief feature in stoves; every encouragement must, therefore, be given them, in order to promote the proper development of the foliage; they should have a moist, warm, and steady atmosphere, plenty of tepid water at the root, and daily sprinklings overhead with the syringe. The young leaves of the finer *Anthuriums* must be kept clear of foliage, which should be put aside, so as not to impede their growth. Several plants will require stakes, which should be neatly and sparingly applied. All young stock should be shifted before the pots containing it have become filled with roots. Remove such plants as are in flower to the coolest end of the house, if practicable. The propagation of stove plants from cuttings should, as a rule, be suspended for a time, until the wood becomes a little firmer than it is at present, but such as were propagated earlier should be potted as they become well rooted. *Poinsettias*, however, are an exception, and the sooner good cuttings can be obtained from them and rooted the stronger the flowering plants will be. The young shoots nearest the end of the branches may be removed for this purpose, and about four or six of the lower-most left on the old plant if it is to be retained.

**Hardy Fruit Garden.**—Attention must now be paid to thinning and otherwise regulating the young shoots of wall trees, to which an occasional good washing with clean water from the garden engine is very beneficial. Young shoots of trees in nursery beds should be loosely attached to stakes in the form which they are afterwards intended to retain. See that the clay does not prematurely fall off

lately grafted plants, and if it does, replace it with a fresh application. Cut away any spray that may grow upon the trunks of standard trees, also most of the strong shoots that come up in the centre of open or cup-shaped fruit bushes. Remove suckers from Raspberries, fruit tree stocks, &c. As soon as Strawberries are set a good soaking of manure-water should be given between the rows. Prepare nets for these and Cherries.

**Kitchen Garden.**—Earth up and stake advancing Pea crops; give those forming pods good soakings of manure-water, and sow some of Knight's Tall Marrows and early sorts for late produce. Earth up Beans, and top such as have come into flower. Cabbages are tender and good, and are hearting well; when removed loosen the ground which they occupied with a fork and plant Lettuces, Savoys, or Brussels Sprouts; or if Seakale or Potatoes were planted between the Cabbages they will now require the additional room. Prick out or thin in the seed beds Coleworts, and plant out in various positions Lettuces, Cauliflowers, sprouting and close hearting Broccoli, Brussels Sprouts, some Savoys, and Curled Kale. For the main crop of Kale, as well as a large portion of the other crops, the ground cannot be got ready until the early Potatoes are lifted, the transplanted Onions removed, and also some of the earlier Cabbage and Turnip crops. Asparagus cutting, in the case of young plantations, should now cease; but, on old-established ones, "grass" may still be cut until the end of the third week of this month, when green Peas from the open ground will be plentiful. Plant out Celery in prepared trenches, which may be cropped for the time being with Turnips, Spinach, Radishes, Lettuces, Endive, or any other crop that will be soon ready for removal. Beet may now be finally thinned to about 9 inches apart; more room would have a tendency to encourage the growth of large roots, which are objectionable. Thin Parsnips to a foot apart, and Carrots to from 9 inches to 12 inches apart, according to the sort. Frame-sown Carrots are now large and good, first border-sown ones are likewise useable; and for a succession of tender roots, another small sowing of one of the Horn sorts should be again made. Keep up a succession of small salads by repeated sowings; but protect the seeds from birds until they germinate, and afterwards from slugs and snails. Keep the hoe at work amongst growing crops. Save all old refuse vegetables, such as Cabbage and Broccoli stumps, which, together with weeds, &c., should be thrown into a heap to rot. Dead bushes, boughs, and prunings of fruit-trees, old Pea-stakes, and similar material, should be gathered into a separate heap and charred, the ashes and charcoal from which, mixed with manure, making a valuable fertiliser. Dredgings of soot and lime amongst growing crops are very beneficial in obviating the ravages of slugs.

MARKET GARDENS.

Late frosts and cold winds have materially injured the more tender kinds of garden crops. Early French Beans, where unprotected, have been almost annihilated, and not one plant of the first crop of Tomatoes has escaped, so that fresh plantations have to be made. Cauliflowers raised out of doors have been greatly damaged, especially in low situations. Potatoes in exposed places have also suffered; but under the shade of trees they are safe. Strawberries, as a rule, promise to bear good crops. Plant out Tomatoes in well-prepared, rich, and sheltered ground, in rows three feet apart, and place a strong stake alongside of each. Those not yet planted out keep in frames, from which the sashes are removed, except when frost is apprehended. Protect Cucumbers in frames during cold nights with litter, but remove it early in the morning; and throughout the day, if favourable, tilt up the sashes at the back about an inch. Water abundantly, thin the shoots and fruit, and use tubular glasses for crooked fruits. Glasses 2½ inches in diameter, a foot in length, and open at both ends, are most suitable for this purpose. Plant out Vegetable Marrows as ground becomes vacant, and if some fermenting manure can be spared to put under each plant, as in the case of the earlier plantations, they start sooner and stronger into growth than they would if merely planted in the open ground, and only protected with handlights. Loosen the soil about those first planted out, and draw the earth around them in the form of little basins for the retention of water. Tilt up with a flower pot the south side of the handlights, which in all cases must still be used to protect the plants. Draw a little ridge of soil along the north or east side of rows of French Beans, in order to partially protect the young plants. Sow for succession and crop between the rows with Turnips, Radishes, Spinach, or Lettuces. Asparagus beds are still yielding a fair crop, but the time is at hand when cutting must be discontinued, as the plants were longer in coming into bearing this year than usual. Cutting may be continued until about the end of June. French Beans, Beet, Lettuces, Nasturtiums, &c., may be grown on the tops of the ridges. Turnips from early sowings are pretty good; hoe and thin succession ones, and sow again if necessary, just as the plants are germinating. If some lime and soot be scattered over the ground it

greatly prevents the attack of the Turnip fly. Tie Cabbages around the middle with a piece of matting, to assist them to heart. Thin and stir the soil amongst spring sown ones. Coleworts are germinating, and those saved for seed are forming seed-pods. Seakale is pushing up strongly. Lettuces planted amongst the rows are being tied, and such as are fit are being removed for market, thus the Seakale gets additional light. Cabbages, Cauliflower, Lettuces, Turnips, and Radishes are generally the crops that are planted or sown along with Seakale; in fact, anything will do that is fit for removal before injury can be done to the Kale. Keep the short narrow hoes at work amongst Celery, Onions, Spinach, and other small crops, and the larger hoes amongst crops planted in rows a foot or more apart. Earth up, as required, Cabbage, Cauliflower, Potatoes, Peas, and Beans. The earliest crops of Celery may now be planted in single rows, 4 feet or 5 feet apart, the trenches in which the plants are inserted being about 6 inches deep, and a foot or 15 inches wide, with the intervening ridge planted with Lettuces. Transplant Leeks and also Marjoram in rows, a foot apart, and clean the spring sown Onions. Transplant Stocks and also Wallflowers, the former for summer flowering, and the latter under fruit trees or in other places for winter and spring blooming; save the seeding plants. Lift Hyacinth and Tulip roots, dry and store them, and let the ground occupied by them be devoted to Lettuces, Cauliflowers, Spinach, and other crops.

## SOCIETIES, EXHIBITIONS, &c.

### ROYAL BOTANIC SOCIETY.

JUNE 11TH & 12TH.

THIS was a good show as regards plants; but fruit was scarce. The day was fine, and the attendance of visitors large. The grounds were most delightful, and the great show of Rhododendrons furnished by Messrs. Lane, of Berkhamstead, was of itself attraction sufficient to bring together a large company.

**Stove and Greenhouse Plants.**—These, to a great extent, consisted of plants fully described in former reports; nevertheless, they were reproduced in a remarkably fresh and well-flowered condition. In the class of twelve plants in flower, Mr. Baines was first, with a fine specimen of *Anthurium Scherzerianum*, *Boronia pinnata*, *Dracophyllum gracile*, *Ixora coccinea*, and some Heaths, *Azaleas*, and *Aphelaxis*. Mr. Ward, Leyton, was second; and Mr. J. Wheeler, Stamford Hill, third. For six plants in flower, Mr. Baines was again first, with *Hedera talipiferum*, *Dipladenia crassinoda*, *Ixora coccinea*, *Phenacoma prolifera*, and two Heaths. Mr. J. Wheeler was second; and Mr. W. Kemp, Guildford, was third. In the nurserymen's class for half a dozen plants in flower, Messrs. Jackson and Sons, Kingston, were first, with a fine specimen of *Ixora Griffithii*, a grand *Allamanda nobilis*, and others. Mr. E. Morse, Epsom, was second; and Mr. B. S. Williams, Holloway, third. For twenty plants in 12-inch pots, Messrs. Jackson were first, with a very fine group of medium-sized specimens, including *Hibbertia Readii*, *Pimelea spectabilis*, *Tetratheca verticillata*, *Stephanotis*, and others; Mr. J. Wheeler was second, and Mr. G. Wheeler third. For twelve plants shown under the same conditions, Mr. Ward was first, with remarkably fine plants of *Stactis profusa*, *Kalosanthes Fredricki Desbois* (one mass of brilliant red flowers), *Bougainvillea glabra*, *Phenacoma prolifera* *Barnesii*, and various others. Mr. E. Morse was second in this class, and Mr. W. Kemp was third.

**Orchids.**—These were fully as good as any that have appeared this year at any previous metropolitan show. In the amateurs' class of twelve exotic Orchids, Mr. Ward was first, with a plant of *Masdevallia Harryana*, with nine beautiful flowers, two varieties of *Odontoglossum Alexandre*, *Cypripedium villosum*, *Lycaste Skinneri*, a grand specimen of *Phalenopsis grandiflora*, good plants of *Acrides Larpentae* and *Lobbii*, and others. Mr. Cuthbert, Chase-Park, Enfield, was second, having good examples of *Dendrobium Dalhousianum* and *Vanda Batemani*, and Mr. G. Wheeler was third. In the amateurs' class of six plants, Mr. Ward was again first; he had a superb specimen of *Cypripedium Stonei*, with three flower spikes, Mr. R. Ritchie, Frognal, Hampstead, was second, and Mr. J. Wheeler third. In the nurserymen's class of a dozen Orchids, Mr. B. S. Williams was first with large and fine plants, and Mr. Wm. Bull was second with somewhat smaller, but still very fine plants of a rare and choice description. Mr. B. S. Williams was also first with half a dozen in the nurserymen's class, the kinds being *Thunia alba*, *Anglora Closesii*, *Saccolabium guttatum*, *Cypripedium caudatum*, *C. barbatum superbum*, and a specimen of *Acrides Larpentae*, with three flower spikes. Mr. E. Morse was second with a very fine group, and Messrs. Jackson and Sons third.

**Roses.**—From Messrs. Paul and Sons came nine very fine specimen Roses in pots, remarkable for the size and freshness of their blooms. The sorts were *Horace Vernet*, *Reine du Midi*, *Charles le Fevre* (fine), *Celine Forestier*, *Nephtes*, *Francis Fontaine*, *Madame Victor Verdier*, *Madame Julie Doran*, *Juno*, and *Charles Lawson*. Some good cut blooms of Roses were exhibited by Mr. W. Chard, Clarendon Park, Salisbury, and J. Hollingworth, Esq., Maidstone. Mr. R. Webb, nurseryman, Reading, showed a marvellously fine collection of blooms of *Marechal Niel*, and also branches of it, on each of which were four blooms in a cluster.

**Pelargoniums.**—Of these there were fine collections, some of the show varieties being individually of prodigious proportions. For nine

show kinds Mr. W. Nye, gardener to E. Foster, Esq., Clewer Manor, Windsor, was first, and Mr. Ward second. Both these groups consisted of plants some 4 feet in diameter, and bearing clouds of flowers; the sorts were chiefly—*Madle. Patti*, *Lord Clyde*, *Rob Roy*, *Woman in White*, *Shakespeare*, *Fair Rosamond*, *Elegant*, *Caractacus*, *Alabama*, and others. Mr. James and Messrs. Dobson and Sons, received equal fourth prizes. In the class of six show sorts, Mr. J. Weir, Hampstead, was first; Mr. James, second; and Mr. McElroy, third. For six fancy sorts Mr. Weir was first with Mrs. Mendel, *Crystal Beauty*, *Miss-in-her-teens*, Mrs. S. Hodgson, *Liberty*, and *Roi des Fantaisies*; Mr. James was second; and Mr. King, Walsey Grange, Esher, third. Mr. Thomas Petridge, Uxbridge, showed twenty sorts of tricolor *Pelargoniums*, all very fine and distinct; and Mr. Wm. Paul, Waltham Cross, exhibited a collection of tricolor, bicolor, and ordinary zonal sorts grafted as standards, also a group of dwarf tricolor kinds, and cut blooms of zonal sorts.

**Heaths.**—There were but few sorts amongst these to which we have not already referred in previous reports; those from Messrs. Jackson were, however, all that could be desired, and the same may be said of groups from Mr. Ward, Mr. Kemp, Mr. Morse, and Mr. J. Wheeler.

**Hardy Herbaceous Plants.**—Every successive show furnishes evidence that these are coming more and more into favour. The best exhibition of them on this occasion came from Mr. Ware, Tottenham. In this group were *Veronica Barrelieri* and others, *Libertia grandiflora*, *Cypripedium spectabile*, and *Dianthus alpinus*, a great assortment of *Funkias*, *Viola persicifolia*, *Equisetum Drummondii*, the foliage of which was very fine, *Delphinium nudicaule*, a hose-in-hose variety of *Mimulus*, and many kinds of *Sedums*, *Saxifrages*, and other plants. For a dozen specimens of herbaceous plants, Mr. R. Parker, Tooting, was first, with several varieties of double-flowered *Pyrethrums*, *Iberis correteifolia*, some varieties of *Iris germanica*, *Spiraea japonica*, *Veronica verbenacea*, *Anthericum liliastrum*, *Aquilegia cœrulea*, and *Armeria plantaginea*. Mr. Ware was second. For cut flowers, Mr. Parker was again first, and Mr. Ware second, both having extremely fine collections. Mr. Ware showed some fine blooms of English and fancy Pansies, as did also Mr. Hooper, of Widcombe Hill, Bath, whose flowers were of great merit, being wonderfully large and brightly coloured.

**Ferns.**—These were large and the plants in vigorous health. For six stove and greenhouse sorts, Mr. Baines was first with fine plants of *Cyathea dealbata* and *Dicksonia antarctica*, huge specimens of *Gleichenia rupestris* and *Spelunca*, a large pan of *Davallia bullata*, and a very fine example of *Lomaria zambicifolia*. In another class of six stove and greenhouse Ferns, Mr. R. Ritchie was first with a very fine half a dozen, consisting of a grand specimen of *Davallia Mooreana*, *Pteris scaberula*, *Lomatia gibba*, *Adiantum Farleyense*, *Gleichenia microphylla*, and *Dicksonia antarctica*. Mr. G. Wheeler was second in this as well as the previous class, and Mr. J. Jeal, Regent's Park, third. Mr. G. Wheeler received a first prize for a pair of fine tree Ferns.

**Fine Foliaged Plants.**—In this class, and also in that of fine foliaged herbaceous plants, there seemed to be some confusion; in some cases they consisted of stove plants, such as *Caladiums*, and in others, wholly of hardy plants, such as *Funkias*, *Sedums*, &c. For six fine foliaged plants, Mr. Baines was first with fine examples of *Sarracenia*, a *Croton*, a plant of *Gleichenia Spelunca*, one of *Dasylicron astrostrichum*, and another of *Theophrasta imperialis*. Mr. Foreman was second with a fine example of *Cupania filicifolia*, and Mr. R. Ritchie was third. For six fine foliaged herbaceous plants, Mr. Jeal was first with six large *Caladiums*; Mr. T. S. Ware second with hardy plants, consisting of *Heimerocallis Kwanso*, fl. pl. fol. var., *Funkias*, the variegated *Sedum japonicum*, and the variegated *Spiraea ulmaria*; Mr. G. Wheeler was third.

**Caladiums, Begonias, and Gloxinias.**—In the class of six *Caladiums*, Mr. Ritchie was first, with very fine plants; Mr. G. Wheeler second; and Mr. J. Prisman, The Ferns, Tunbridge Wells, third. For half a dozen *Begonias*, Mr. Walker, Gunnersbury House, Acton, was first, with good plants of the old-fashioned ornamental-leaved kinds—viz., *The O'Donoghue*, *Princess Charlotte*, *Rex*, *Marshallii*, *Rollissonii*, and *Roi Leopold*; Mr. Farrow was second. From Mr. King came a fine group of *Gloxinias*, the specimens being large and profusely flowered; Mr. Farrow and Mr. Foreman likewise supplied *Gloxinias*.

**Palms.**—Mr. Wm. Bull furnished half a dozen very fine Palms, for which he was awarded a first prize. They consisted of *Areca Baueri*, *A. sapida*, *Kentia Forsteriana*, *Hyophorbe Verschoffeltii*, *Dæmonorops melanochaetus*, and *Calamus adspersus*.

**Miscellaneous Subjects.**—Messrs. Veitch and Sons contributed an admirable collection of plants, consisting of Japanese Maples, some of the newest and best of *Dracenas*, *Crotons*, *Palms*, *Ferns*, the fine *Aralia elegantissima* and *Veitchii*, *Dieffenbachia Braziliensis*, several pretty little plants of *Sonerilas*, and several new and rare Orchids. The same firm likewise exhibited a collection of *Rhododendron* and hardy *Azalea* blooms, also blooms of double-flowered *Pyrethrums*, and a branch of *Fremontia californica* laden with large yellow flowers. Mr. B. S. Williams showed some pretty new plants, and Messrs. Rollisson a fine group of the finer kinds of stove and greenhouse plants. Mr. Bull exhibited a group of the newer sorts of *Marantas*, *Dracenas*, *Crotons*, *Palms*, and *Cycads*. Messrs. E. G. Henderson showed a fine group of herbaceous *Calcœolarias*, and another of stove and greenhouse plants. Messrs. Jackman and Son, Woking, contributed a collection of cut flowers of *Clematides*, also some dark-coloured flowered *Clematides* in pots. Mr. Adam Forsyth, of the Brunswick Nurseries, Stoke Newington, sent some flowers of Chinese *Chrysanthemums*; and Messrs. Adcock and Co., Princes Street, a stand of artificial flowers.

**Fruit.**—Pines were in no way remarkable; they came from Mr. J.

Hepper, Acton, and Mr. W. Birse, Finchley, and were confined to the Queen variety. For a green-fleshed Melon, Mr. Cross, Renacombe Park, Cirencester, was first with a nice little fruit of Bellamore Hybrid; Mr. Hepper was second with Strathfieldsay. The winning scarlet-fleshed Melon was a fine little fruit of the Morcton Hall, from Mr. W. Coleman, Eastnor Castle, Ledbury; Mr. Hepper was second with scarlet Gem; the last-named exhibitor also showed a collection of Melons. Grapes were very good; for a basket of 12 lbs. of any variety, Mr. C. Little, Hall Place, Maidenhead, was first, with large and fine fruit of the Black Hamburgh; Mr. J. Smith, Lancashire, was second with Muscat of Alexandria, and Mr. G. Osborne, Finchley, third with Black Hamburgh. For a dish of three bunches of Black Hamburgh Grapes, Mr. J. Bashford, E. Sutton, Kent, was first with large and fine fruit; Mr. Coleman was second with fine symmetrical bunches, closely set, and perfection as regards colour, plumpness, and bloom; indeed, they appeared to be the best finished and ripened clusters of Grapes in the exhibition; Mr. J. Bannerman was third with excellent fruit. For a dish of any other black sort Mr. Bannerman was first with very fine bunches of Black Prince, the berries of which were well ripened and beautifully bloomed; Mr. T. Davies, Turville Park, Henley-on-Thames, was second with the same sort. For a dish of Muscat of Alexandria, Mr. Priest, Enfield Green, Staines, was first, and Mr. Smith, second. For a dish of any other white Grape Mr. H. Stapleton was third with white Frontignan. The Peaches were very fine; for two dishes Mr. Coleman was first, with A Bee and Early Grosse Mignonne; Mr. Bennet, Hatfield, was second, with early Grosse Mignonne and Royal George; Mr. Bannerman was third, with Millet's and Royal George. For two dishes of Nectarines, Mr. Kemp was first, with fine fruits of Hunt's Tawny and Elrage. For two dishes of black or red Cherries, Mr. G. Ward, Bishop Stortford, was first with Rose de Lyons, the dark red fruits of which were very large and fine; and Mr. T. Mills was second with Black Circassian and first with Elton in the class of white Cherries. Strawberries were of excellent quality; Mr. Davies was first for a dish of President; Mr. Bennet second, with Dr. Hogg; and Mr. J. Plumbridge third, with Sir Jos. Paxton. Mr. Coleman was first with a dish of excellent Brown Turkey Figs. Mr. W. Gardiner, Lower Ealington Park, sent some Apples in a good state of preservation. Mr. Cadger, Wrotham Park, Barnet, showed a brace of his hybrid white-spined Cucumber, also a double one consisting of two distinct fruits joined together; each representing the different parents from which this hybrid was raised, viz., the Linton and Cox's Volunteer.

**Certificates of Merit.**—These were awarded to the following:—

*Aralia elegantissima*, *Adiantum speciosum*, *Cypripedium Stonei platyterium*, from Messrs. Veitch and Sons.

*Dracena amena*, *Cyathus Burkei*, *Cycas imperialis*, *Odontoglossum Inseleyii leopardiannum*, *Chamaerops humilis variegatus*, *Campsisium filicifolium*, *Croton grande*, *Phyllanthus nivosus*, *Dracena Fraseri*, *Croton majesticum*, from Mr. Wm. Bull.

*Echmea bracteata* (Rollisson), a strong growing Bromeliad, with a tall branched flower spike.

*Gloxinia Brilliant* (Rollisson), a beautiful scarlet finely formed flower.

*Aralia Guilfoylei*, *Cydobothra pulchella*, *Stadmannia sorbifolia*, *Coleus Verschaffeltii splendens*, from Messrs. E. G. Henderson & Son.

*Clematis Miss Crawshaw* (Jackman), a rosy lilac, well-formed flower.

*Clematis Mrs. Geo. Jackman* (Jackman), a large, white, and well-formed flower.

*Saxifraga nepalensis* (Parker), a strong-growing, long, and silvery-leaved kind, bearing a great pyramid of flowers and producing from the base a large quantity of lateral flower spikes. It is a grand exhibition specimen, one plant being sufficient for a large pot.

*Agave Gilbeyii* (Peacock), a dense growing plant in the way of *univittata*, with the spine of *xylocantha*.

*Agave striata* var. *Richardii* (Peacock), a dwarf, compact plant of the *Bonaparte* type.

*Agave Baxterii* (Peacock), a medium-sized growing plant, with entire margins.

*Agave Kerchovii* (Peacock), a strong-growing sort, with formidable spines a considerable distance apart; quite distinct.

*Echinocactus Murbelli nigripinus*, a sort deeply channelled into six ribs, covered with small snowy-like spines.

*Phlocereus foveolatus* (Peacock), in the way of the "Old Man" Cactus, but having strong brown spines.

## THE RHODODENDRON SHOWS.

NOTHING in the way of flowering plants can surpass in brilliancy the three great exhibitions of Rhododendrons now to be seen in the neighbourhood of London. Among Rhododendron blooms may be found all shades of colour between the purest white and the darkest crimson, and these, too, on plants sufficiently late in flowering to escape spring frosts. High cultivation and careful selection have also a most influential bearing on the character of the flowers, as regards size of trusses, fine form, and pure and brilliant colouring. Somewhat tender sorts, grafted on hardy stocks, often flourish when, on their own roots, they would not succeed. Rhododendrons are not so particular as to soil as is generally imagined; for, although a peaty compost is certainly best for them, they will not only grow, but will flower well in sandy loam, provided it does not contain lime, which they dislike.

**Alexandra Palace.**—Near the Palace, under a large marquee, is Messrs. John Waterer and Sons' Rhododendron exhibition. The ground on which it is arranged is laid out after the fashion of that at South Kensington and the Regent's Park, and the beds are occupied by superb plants of considerable size and of the choicest varieties. In addition to the plants in beds, which are striking and effective in the extreme, there

are fine isolated examples of *Roseum superbum*, *gloriosum*, *Lady Eleanor Cathcart*, and *Everestianum*—all perfect clouds of bloom. New varieties are not plentiful; but many unnamed seedlings are extremely beautiful and promising. Amongst the older sorts, *Dulcep Singh* stands prominent as a dark crimson. *Joseph Whitworth* is still one of the finest purple sorts, and *Lady Dorothy Neville* is another very fine sort. *Michael Waterer* is one of the best of brilliant scarlets, *Lady Tankerville* an extremely pretty and showy delicate Rose, and *Ellen Waterer* one of the finest flowers, of a white colour, edged with scarlet.

**Royal Horticultural Society's Garden.**—Under a marquee here, some 60 yards in length by 10 yards in width, are Mr. Anthony Waterer's Rhododendrons. Here, as elsewhere, the ground is tastefully laid out in beds, raised on turf terraces, intersected by winding walks. The plants are now at their best as regards bloom, and are well worthy of a visit. All the plants assembled here have been grown at Knap Hill, where the soil is particularly well suited for them. Among them are some extremely pretty unnamed seedlings, but such fine kinds as *Mrs. William Bovill*, *Sir C. Napier*, *Alexander Dancer*, *Lady Clermont*, *Stella*, *Wm. Downing*, *Mrs. Milner*, and others will be difficult to match as regards effect.

**Regent's Park.**—Here Messrs. Lane's Rhododendrons nobly uphold the position assigned to them. The tent in which they are shown is tastefully laid out, and the Rhododendrons as tastefully intermingled with other things, the dense mass of colour being relieved by the presence of *Laburnum*, choice *Conifers*, *Ivies*, and a few other miscellaneous ornamental plants. The Rhododendrons shown here have all been grown in a loamy soil and they serve to illustrate the fact that peat is not essentially necessary for their growth; even if they were in peat it would be difficult for them to produce greater masses of flowers than they are now bearing. Amongst the white flowered sorts *Purity*, *Mrs. John Clutton*, and *The Queen* are very fine; and amongst the red or darker coloured kinds are *Madame Van der Weyer*, *Concessum*, *Lord John Russell*, *fastuosum fl. pl.*, *Caractacus*, *Alarm*, and many others.

## COVENT GARDEN MARKET.

JUNE 13TH.

From the Continent and Channel Islands we have this week several thousands of packages of Cherries, Apricots, Tomatoes, Strawberries, Artichokes, Turnips, Carrots, and small salads. Of New Potatoes great quantities have also arrived, and are readily sold at 2d. and 3d. per lb.

**Prices of Fruits.**—Apples, per doz, 2s. to 3s.; Apricots, 2s. to 3s. per doz.; Cobs, per lb., 2s. to 2s. 6d.; Cherries, per box, 2s. to 4s.; Gooseberries, per quart, 3d. to 6d.; Grapes, hothouse, per lb., 6s. to 15s.; Lemons, per 100, 6s. to 10s.; Melons, each, 6s. to 12s.; Oranges, per 100, 6s. to 12s.; Peaches, per doz., 18s. to 36s.; Pine-Apples, per lb., 8s. to 12s.; Strawberries, per oz., 6d. to 1s.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 3s. to 6s.; French, 4s. to 12s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet, Red, per doz., 1s. to 3s.; Broccoli, each, 6d. to 9d.; Cabbage, per doz., 1s. 6d. to 2s.; Carrots, per bunch, young, 1s., old do., 8d.; Cauliflower, spring, per doz., 8s. to 12s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 4s.; Cucumbers, each, 1l. to 1s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Leeks, per bunch, 6d.; Lettuces, per doz. 1s. to 2s.; Mushrooms, per pot, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 8s. to 12s.; button, per quart, 1s.; Parsley, per doz. bunches, 6s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 2s. to 3s. 6d.; Potatoes, new, per lb., 3d. to 6d.; Radishes, cr. doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 8d. to 1s.; Salsify, do., 1s. to 1s. 6d.; Scorzonera, per bundle, 1s.; Shallots, per lb., 6d.; Spinach, per bushel, 3s.; Turnips, old, per bunch, 6d., young do. 1s. 6d.

## ANSWERS TO CORRESPONDENTS.

**PEARS (E. T. R.)**—Your Pears have evidently been eaten away by larvæ, but no larvæ were in your letter. We have seen the creature, however, and they are figured in *Smee's "My Garden,"* p. 499, where you will find a brief account of such pests.—**VINE LEAVES (E. T. R.)**—Your Vine leaves are thickly infested with the white mycelium of *Oidium Tuckeri*; the orange coloured spots appear to be a merely more luxuriant growth of this mycelium upon damaged spots on the leaves—where the mycelium is orange the tissues are quite decomposed.—**BERRIES (J. P. F.)**—Messrs. Dickson and Co., Chester.—**SLUGS (J. W.)**—Try what effect air-slaked lime has on them.—**SAXIFRAGES (Rocks.)**—Your three specimens of a variety of *Saxifrage* belong to a section of which all seem to be linked together by intermediate forms. Seedlings of some of the specimens are endless; as, for example, the varieties of *S. longifolia*. No. 1 seems to come between *S. aizoon* minor and *intacta*; 2, between *S. pectinata* and *S. crustacea*; 3, between *S. hughata* and *S. vernalis*.—**SEDUMS (Rocks.)**—*Sedum dasycarpum* and *S. corsicum* are different plants in cultivation, the former being the larger of the two, and pale coloured. The latter, *S. corsicum*, is dwarf and compact, and of a much darker colour all over than *S. dasycarpum*.—**PANSIES (Mrs. E.)**—Cuttings of these should be struck in August and September, and wintered in a cool frame. Young growing plants always produce the best blooms. A mixture of leaf-mould, loam, and well-decayed stable manure suits them perfectly; and, where the soil is heavy, add an equal proportion of good sharp sand. Pansies prefer a shady border, as, when exposed, the summer sun burns out their colour and prevents them from forming good flowers.—**NAMES OF PLANTS (Anon.)**—Your leaf seems to be a barren frond of a *Polystichum*—probably *P. angulare*. Ferns are not easily distinguished in the barren state.—**(Pyrus.)**—1. *Pyrus torminalis*; 2. *Pyrus domestica* (true Service); 3. *Pyrus pinnatifida*; 4. *Pyrus intermedia*; 5. *Pyrus spura*.—(Usk.)—Apparently a seedling *Hex latifolia*; certainly not a *Ligustrum* or *Euonymus*, as they have opposite leaves.—(E. S.)—1. *Cotoneaster microphylla*; 2. *Gymnadenia conopsea*; 3. *Some Beris* (indeterminable); 4. *Hemerocallis flava*; 5. *Habenaria bifolia*; 6. *Gnaphalium arvenarium*; 7. *Allium Moly*; 8. *Cephalanthera grandiflora*.—**ANIAMUM CAPITULOSUM VIBERIS (F. H.)**—It will live out of doors in sheltered warm situations, but in cold localities it succeeds best under glass.—**PHIENOCOMA (Junior)**—Next week.

\* Several of the plants that received certificates on this occasion have received similar awards elsewhere, and have been described by us in former reports.

## THE GARDEN.

"This is an art

Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### LIME-KILN HEATING.

AN excellent paper on this subject was read the other day by Mr. Cowan before the Dublin Horticultural Club:—Within a short period (said Mr. Cowan), almost all the materials used for heating have been doubled in price. This, of course, in a material degree, increases the first cost, and especially when we consider that labour has also become much higher. But the great increase in the first cost is not, after all, such a serious matter as the enormous increase which has taken place in the price of fuel. When a building has been fitted with a good heating apparatus the expense may reasonably be expected to be done with for years, but this is not the case with fuel, which is a continual and a heavy tax. A great deal has been done in the way of introducing boilers calculated to economise heat and save fuel, but still, as some one has remarked, "no more than a certain amount of heat can be got out of a given quantity of fuel, economise it as you will." Consequently, with the best boiler that can possibly be procured, a considerable quantity of fuel must be consumed in comparison with the extent of buildings to be heated. And it is just here that the great value of lime-kiln heating is made apparent. I do not claim for it merely a greater degree of economy than other systems. I claim for it the merit of heating any extent of building by hot water entirely free of cost, except the first outlay for materials and construction of the apparatus. The depth of the stokehole required is, of course, greater than would be the case for a boiler only, but very little more than is needed for a tubular boiler; from 10 to 12 feet under the level of the flow pipes will admit of a good-sized apparatus being fixed; 13 feet, with a proper boiler, would be sufficient for an apparatus to heat 3,000 feet of 4-inch piping. Much less could be made to do, but it would not be so satisfactory. The kiln is built very much in the shape of an egg, with the narrow end downwards, and is lined inside with fire bricks or other suitable material, another wall is carried up at the same time and of the same form as the one forming the kiln, but with an intervening space of about nine inches. This space is filled up with sand as the two walls are carried up, the sand being put there for the purpose of retaining the heat, which it does most effectually. When the kiln has been carried to the proper height, a hot-water boiler is placed on the top, and built in just the usual way, but of course there are no fire bars required, and only one door; this door is the place at which all the fuel and stones are put in, and the burned lime is drawn out at the bottom, a small opening being left there for that purpose, just sufficient to admit of a shovel being introduced. The working of the apparatus is extremely simple, and may be taught to any ordinary garden labourer in a very short time. When the extent of the building to be heated is not great, I recommend the use of the ordinary saddle boiler, on account of its cheapness and durability, and the boiler which I have designed especially for the use of this system is simply a saddle boiler with some additions to it, to make it better adapted to this system. In order that the merits of this boiler may be appreciated, it must be understood, that when anthracite coal is used there is almost no smoke and scarcely any soot to collect in the flues, consequently the great object is to confine the heat sufficiently long about the boiler until the greater part of it has been utilised, and it will at once be seen that this boiler is eminently calculated to attain this end; it has also the advantage of being low, and consequently does not increase the necessity for depth of stokehole to a very great degree.

But, it may be asked, why place the boiler on the top of the kiln? why not form the whole, or at least a part of the kiln with the boiler? and thus have the fire right in the centre of it. A very good answer to these questions has been furnished by Mr. Collis of Millmount, Kilkenny. I was much surprised to learn that that

gentleman had had an apparatus for burning lime and heating his garden structures on the hot water system, at work for the past four years. I did not know that such a thing had been done in either this or any other country until some time after I had completed my patent; I did not even know anything for certain about it until about three weeks since, when a gardener who was sent by his employer to inspect my system at Dromore was also requested to call there on his way, and from the account which he gave me, I could learn that Mr. Collis's principle was entirely wrong, although I confess I did not expect that it could be such a failure as Mr. Collis himself proves it to be in an account which he has published in *THE GARDEN* (see p. 441). His statements are accompanied by an illustration, not, however, of the apparatus which has been in use for four years, but of one which he is now having erected. The illustration in question shows a tubular boiler  $3\frac{1}{2}$  tons weight, fixed right in the centre of a kiln  $17\frac{1}{2}$  feet deep, and Mr. Collis states that he expects it will heat 5,000 feet of 4-inch piping, and no one can deny that it is quite large enough for this purpose, but he has not yet tried it, and I venture to express my strong conviction that it will never do anything of the kind with satisfaction.

Mr. Collis says that the kiln which he has worked for four years is 3 feet 6 inches in diameter, and 12 feet high. The boiler, a horizontal tubular one, is 4 feet high, and encircles the kiln near the top, the mouth being left open, and the smoke and smell allowed to make the best of their way out of the place. This kiln and boiler, Mr. Collis tells us, are capable of heating a thousand feet of 4-inch pipe sufficiently for ordinary forcing purposes; and, as he wished to heat 2,000 feet, he had to supplement it this spring with an ordinary 3-foot tubular boiler. Thus, all that Mr. Collis has been able to accomplish with his kiln hitherto is to heat 1,000 feet of 4-inch piping. I wish particular attention to be paid to this statement, for he tells us that to accomplish this he had to burn two tons of culm per week; and, more wonderful still, he only burnt three tons of stones with his two tons of culm. To burn three tons of stone in our kilns at Dromore, we require just 14 cwt. of culm, and that amount heats to any required degree, with an ordinary saddle boiler, 1,000 feet of 4-inch piping; so that Mr. Collis requires just almost three times the amount of fuel to burn the same quantity of lime, and to accomplish the same amount of heating which we do, and a boiler probably three times the cost of ours. The one he is building in now cannot have cost much less than £200, and, calculating by the same scale which he gives us for the first, must burn about 10 tons of culm per week in order to heat 5,000 feet of 4-inch pipe. Culm costs him only 8s. 6d. per ton; but how would the case stand if it cost him, as it does us, 25s. per ton? Add to this the smoke and disagreeable smell which must come from an open kiln, consuming such an enormous quantity of fuel, and you have a perfect picture of that which has been put forth in one of our leading gardening papers to prove that the system which I am advocating is not new. Mr. Collis says he does not believe that heat can be had free of cost in his locality. Why, if I were in his locality, I should expect to make a handsome profit from the lime, besides having the heat free. With regard to the position of the boiler inside or on the top of the kiln, it is well to bear in mind the following fact:—When a kiln is formed of fire-bricks, they get heated to a very high temperature, and very materially assist in the burning of the lime; but this is not the case with a hot water boiler—it is kept comparatively cool by the circulating of the water, and thus in place of assisting in the burning of the lime, as the bricks do, it very materially hinders it—so much so, that Mr. Collis informs us that it causes the consumption of three times the amount of fuel; and there is another cause for Mr. Collis's want of heating power in proportion to the amount of fuel consumed, namely, that the greater part of his heat passes off by the mouth of his kiln. I think, then, that what I have stated will go far to prove that the top of the kiln is the right place for the boiler, and as my patents secure me equally well in putting it inside the kiln, you will see that I am only actuated by a desire to show the best means of obtaining the desired end. In order that the kilns may be allowed to continue burning, and the heat at the same time turned off the building which they are heating, I propose to fix the supply cistern somewhat near the boiler, and to have it somewhat larger than usual; into this cistern I propose to take two pipes in place of one, one from the flow and one from the return pipes, and when the water is shut off all the buildings, it will circulate into the cistern, and the house can thus be kept quite cool, and at the same time abundance of heat kept at hand to turn on at a moment's notice. This is a very simple arrangement, and not at all expensive, and will secure perfect command of the heat at all times. In conclusion, I may state that I expect this system of heating horticultural buildings will bring about a very considerable change in the production of fruit and flowers in this and other countries.

## NOTES OF THE WEEK.

— THE Irises round London are in full beauty now. They appear to thrive better on stiff clay soils than any other important class of hardy plants, and this fact should be taken note of by all whose gardens are on such soils.

— AMONGST the industries in which soldiers employ their leisure time in France, not the least is Strawberry cultivation. At Bagnolet, near Paris, 300 soldiers from the forts of Rosney and Romainville are daily occupied for six hours in Strawberry culture.

— It was announced, at the Royal Horticultural Society's meeting last Wednesday, that, on the occasion of the Shah's visit to the Albert Hall on Monday evening next, the conservatory would be illuminated, and that nobody but those furnished with Fellows' tickets would be admitted.

— AMONG bulbous plants at Kew we noticed the following the other day beautifully in flower, viz., *Calochortus Leichtlinii* and *nitiflorus*, a nice tuft of *Cyclobothra pulchella*, with pretty golden yellow blossoms; *Lilium tenuifolium*, with small deep red flowers resembling those of *L. chalcedonicum*; and though not, strictly speaking, a bulbous plant, the curious *Arum crinitum*, with its singular-looking grey spotted spathes.

— A WRITER in the *Prairie Farmer* says that, with the exception of the Peach belt along the shore of Lake Michigan, Peaches are generally killed through that State, and it is feared that many of the trees are also destroyed, the thermometer having sunk the past winter to 35° and 40° below zero. Apples, however, promise a full crop; Grape Vines are badly cut down, and Pear and Plum trees are much injured.

— M. LOUIS VAN HOUTTE, of Ghent, is about to publish a work on Orchids, which will be embellished with all the figures of those plants which have appeared from time to time in the 18 vols. of the *Flore des Serres*. Those who are familiar with the beauty of the coloured engravings with which that publication is illustrated will not be slow to recognize the importance of the reproduction of the Orchid plates in a separate work treating of that interesting family of plants.

— AN example, which may be profitably followed in many of our public institutions of learning, has been set by the students of the Friends' Academy, New York, in the formation of a Horticultural Society among themselves, twenty-four having joined at its organisation. The small admission fee is expended in the purchase of seeds, plants, and bulbs. A leading object of the society is ornamenting the grounds of the institution. In addition to the knowledge of plants which they thus obtain, the pleasant and healthful exercise and the intellectual recreation attending such work can hardly be over-estimated.

— OF the various species of *Linum* with which our gardens are enriched, probably the most ornamental, as a border plant, is *Linum narbonneuse*, which yields a profusion of pale blue flowers for a long time during the summer months. Of this a good white variety may now be seen in bloom in the herbaceous grounds at Kew, where it forms a worthy companion to the normal species. Associated with it may also be seen two other plants that are not so well known as they deserve to be—viz., *Ethionema orientale*, one of the prettiest species of the genus to which it belongs, and *Oxytropis baicalia*. The former has erect stems, woody at the base, and bears pretty racemes of bright rose-coloured flowers. The latter has dull white flowers, resembling those of *O. campestris*. On the rockwork may also be seen the rare *Cathcartia villosa* in bloom.

— THE presentation of a testimonial to Mr. Appleby (on the occasion of his retirement from his situation as foreman of the Dorking Nursery, where he has been employed upwards of 18 years), which was originally intended to take place at the approaching Bath Show, has, in consequence of the Secretary and Committee not being able to complete the necessary arrangements in time, been postponed to Sept. 3, when it will be made at the Great International Exhibition of Fruit at Manchester. Mr. Appleby has done good service to the cause of Horticulture, in raising some fine varieties of hardy Ferns, and we have no doubt that he will still continue to exercise his skill in that direction in the nursery which he is about to establish on his own account at Dorking.

— MR. MEEHAN, in his late travels in the Rocky Mountains, came on a tract covered profusely with one of the small creeping Euphorbias, probably *E. cordata*, in which a large quantity grew perfectly erect. Sometimes only a portion of the plant exhibited this character, at other times all the plant was upright. In all these cases the plant was attacked by a small fungus, *Acidium Euphorbiae hypericifoliae* of Schweinitz. He thought that the fact that this little fungus should be able to make a usually creeping plant, rooting from every joint, entirely lose this character and become erect, was worthy of some notice by students in this branch of botany.

— THE floral decorations at Charing Cross Station on the occasion of the arrival of the Shah, last Wednesday, were of the most profuse character, and were exhibited in wonderful variety. The greater part of the flowers, &c., were furnished and arranged by Mr. Dickson, of Covent Garden Market. We understand that Mr. B. S. Williams, of Holloway, has been entrusted with the floral decorations at the approaching festival at the Guildhall.

— THAT splendid hardy shrub, *Xanthoceras sorbifolia*, which was named and described by M. Decaisne some years since, and of which only a single specimen exists in the gardens of the Muséum at Paris, is now completely covered with flowers. These are of a pure white, slightly tinged with lilac-rose on the margin, and are produced in dense and effective clusters. Few flowering shrubs are finer than this, and, when better known, it cannot fail to become a general favourite.

— M. LOUIS VAN HOUTTE, of Ghent, has just issued the first part of his "Pomone," a remarkable work, devoted to the description of our cultivated fruits. The present number contains descriptions of 431 varieties of Pears, followed by coloured plates representing fifty of the best kinds, which are figured with a degree of art and truth of which it is impossible to speak too highly. In addition to this there are outline figures of thirty-six other varieties. We have never seen anything approaching the beauty and accuracy of the coloured figures, and we are happy to call attention to a work which we believe indispensable not only to all fruit-growers but to all lovers of fruit.

— MR. F. T. WARNER, of Winchester, who for some time has been collecting materials for a Flora of Hampshire, has kindly offered the use of his collections and materials to Mr. Frederick Townsend with the proposal that he should complete the Flora. Mr. Townsend has accepted the offer, and, as much work remains to be done, he invites the assistance of other botanists in furnishing him with lists of plants or in forming these during the present season. The value of lists will be greatly increased if accompanied by specimens, and in all cases exact localities and dates should be given. It is proposed to divide the country into river-basin districts. Letters should be addressed to Sheffield Lodge, Fareham, but parcels to Botley Station, London and South Western Railway. Mr. Townsend will gladly pay postage or carriage of parcels.

— WE have just received from Mr. J. Huntingford Morgan, of 17, Wallham Grove, St. John's, Fulham, a remarkable monstrosity, in the shape of a stem of the common Foxglove (*Digitalis purpurea*), bearing on its summit a huge flower resembling a large-sized rose-coloured Canterbury Bell. It is 2 inches in diameter, and 1½ inch in depth, and stands nearly erect on the extreme end of the stem. The mouth is very open, and is margined by 13 reflexed rounded lobes. It has twelve stamens and a stout pistil an inch long and ½ inch, or more, in diameter. Below it are sixteen flowers of the normal shape and size, in various stages of development. These it resembles in colour both inside and out, but it has entirely lost the characteristic form of the Scrophulariaceae, and is in shape perfectly campanulate. Mr. Morgan informs us that the same plant flowered in the same way last year, and that the large flower on the top of the stem was the first to open both this year and last.

— PREFIXED to the fifteenth report of the East Kent Natural History Society, is a brief but pointed address by the President, Dr. Mitchinson, in which he points out the utility and some of the dangers of Provincial Natural History Societies. He refers to one evil which is apt to result from the labours of such societies, an evil which has with justice been animadverted on from various quarters recently, viz., a morbid mania for indiscriminate collecting, which is apt to lead to the extinction of the rarer fauna and flora of the district. No doubt, as Dr. Mitchinson says, collecting is inseparable from the thorough study of botany and zoology; but, as he forcibly remarks, no sorer sign exists of a spurious pursuit of either or both of these sciences than when rare plants are torn up, and rare animals made still rarer by that selfish acquisitiveness which passes with so many for a love of science.

— WE are anxious to make an appeal to our readers in behalf of the very distressing and deserving case of the idiot son of the late Mr. Robert Glendinning of Chiswick Nursery, Turnham Green. This poor young man has been for nearly the last twenty years an inmate of the asylum at Redhill, depending solely on his parents for the yearly payment of £60 for his maintenance there. His mother, the last surviving parent, having recently died, and the other members of the family being quite unable to continue the yearly pension in question, he will be turned out helpless upon the world if some immediate steps are not charitably taken in his behalf, in order to place him on the foundation of that Institution. Subscriptions and votes for that purpose will be thankfully received by Mr. Francis Dancer, of Little Sutton, Chiswick, and also by Mrs. Bridges, Rupert House, Chiswick.

## THE INDOOR GARDEN.

### A FINE SPECIMEN OF RAMONDIA PYRENAICA.

WHEN at Benthall Hall, last year, I was much struck by the beauty of a fine specimen of this plant in full bloom in Mr. Maw's drawing-room. It is unusual to see alpine plants grown into good specimens, and still more so to see them gracing the dwelling-house with their presence. This Pyrenean plant is one of the loveliest of "alpines," and also one of the slowest growers, but, as will be seen by our illustration, it has been grown at Benthall Hall into an abundantly blooming healthy specimen. The engraving is from a photograph taken at Benthall Hall. Mr. Maw finds little difficulty in its culture, except that it is impatient of excessive drought, and that under a hot sun it is liable to turn brown and lose its foliage, which weakens the plant for the succeeding year. It is doing fairly with him in an open rock border, composed of broken stones mixed with equal parts of sand, loam, and peat, and blooms freely in this situation. In a cold frame it is one of the easiest alpines to grow. It likes thorough drainage, and a cool moist situation. It is repotted every year at midsummer; about seven roots are put in a 12-inch pan. The soil used consists of equal parts of loam and sharp sand, with a little peat or leaf-mould. The pans are set in the shady part of a deep pit. To preserve its beauty unimpaired it is necessary to keep the flowers from exposure to the sun, and also to avoid wetting them in watering. Thus managed, flowering pans of *Ramondia* are lovely objects for at least three weeks, and are well worthy of a place either in the conservatory or sitting-room. W. R.

### MANAGEMENT OF GESNERAS.

GESNERAS being for the most part tuberous-rooted plants, by judicious management can be had in bloom the whole year round. They are not difficult to cultivate; anyone having a Melon or Cucumber pit, or a stove house, which is better, and a Vinery or a warm greenhouse for summer quarters, can grow them well. They like partial shade and plenty of moisture when growing, both in the atmosphere and at the roots. A suitable soil may be made up of one half turfy loam, the other half being peat, leaf-mould, and well decomposed manure in equal parts; there should also be a liberal supply of silver and sharp river sand, and a good drainage of potshreds or pieces of charcoal. Gesneras should be grown for successional blooming, and as this can be done with a small collection, there should be a series of pottings of the roots. One tuber can be grown in a 48-sized pot, or three or four in a 24-sized pot. Some growers prefer single specimens, which speedily grow into good plants if properly managed, while others prefer large examples, when three or four tubers must be used. The tubers should be started into growth at intervals of from five to six weeks, beginning, say, with the middle of March, and continuing on to early in July, if space can be found for them. The soil should be filled up in the pots to within an inch and a half of the surface, so as to leave room for some top dressing, and it should be gently pressed about the tubers. The pots should then be plunged in a bottom heat of from 70° to 80°, in order to start the tubers into growth, and here they can remain till the shoots are about 4 inches in length, when they may be removed to a warm, dry, and light part of the stove near the glass. There must be no stint of water when required, in fact, Gesneras like plenty of moisture about the roots, so long as there is a free drainage, but they

dislike the lodgement of water on their leaves, and, therefore, they should not be syringed over-head, as the leaves become much disfigured through water lodging on them. Each stalk should be tied to a stake, as the plants make a free growth, and require to be tied out so that the finely-marked leaves may be set off to the best advantage. After all, a single specimen in a pot is better than several of irregular growth; besides, a large pot, containing small plants, frequently has a confused appearance. There must be no neglect after the plants have done flowering. Indeed, to keep Gesneras in robust health, they must be well attended to after flowering, for then the bulbs for the following season have to be matured. In order to effect this, they must be carefully tended, giving them occasional waterings with weak liquid manure; but as the foliage begins to decay, less water will be required, and when the growth is finished, water must be entirely withheld. After this, though requiring to be kept dry, they must not be baked, but should be stored away in their pots in a cold dry place until again required. It is a common practice to shake the soil away from them when dry, and to store the bulbs in dry sand; but the best system is to leave them in their pots, and just start them into growth in the old soil before repotting, for by this treatment the bulbs are not so liable to injury, and the plants consequently flower much stronger.

*Ramondia pyrenaica* (12 inch pan, 51 expanded flowers).

The following varieties are all well worth cultivating, viz. --- *Barlowii*, the leaves of which are bright green, covered with crimson hairs; the flowers are a delicate shade of salmon, slightly spotted on the throat; *Chromatella*, a kind with dark velvety leaves, and elegant erect spikes of drooping rich yellow flowers; *Cinnabarina*, a variety with green leaves, and brightened with flame-coloured hairs, the flowers bright and cinnamon, with a pale throat; *Doncklaari*, a kind with large, darkly-tinted leaves, and bright vermilion flowers; *Exoniensis*, a sort with large, rich, dark velvety leaves, covered with minute red hairs, the flowers deep orange-scarlet, with yellow throat; *Lindleyana*, a sort with rich deep velvety green and red leaves, flowers rosy pink and yellow, freckled with red; *Nigrescens*, a variety with large dark velvety leaves, dark red flowers, the throat light orange spotted; and *Zebrina splendissima*, a kind with leaves handsomely marbled with dark, bright orange scarlet flowers. There are several new continental varieties that are highly spoken of; but the foregoing represent a list of thoroughly good and distinct varieties of acknowledged excellence. R. D.

### GOLD AND SILVER FERNS.

NEXT to the Maidenhair Ferns these rank highest in public estimation. They, however, require more heat, as a rule, than can be afforded them in a greenhouse; a cool stove or intermediate house suits them best, and, where these exist, little skill is required in their management beyond treating them to moderate heat, plenty of water, and shelter from the sun's rays. With the majority of these plants the gold or silver powder on the leaves is easily rubbed off; and, therefore, it is necessary that no water be administered to them through the syringe, or this farina or powder will be washed off. The first of these Ferns on my list is—

*Adiantum sulphureum*.—This I call the Golden Maidenhair, for although named sulphureum, when properly grown, the farina, which clothes the under-side of the pinnule, is of rich choice gold. Think of that, a Maidenhair Fern having all the delicacy and grace of that old favourite *Adiantum cuneatum*, and covered on the under-side with a beautiful golden farina; it grows from 6 to 10 inches high, sometimes more. The fronds are three times divided; the pinnules are plain at the edges when not fertile; but when

laden with sori, the indusium gives them a peculiar crenate appearance, which considerably enhances their beauty. This plant is usually considered difficult to cultivate, and if placed in stove heat, it always presents a weakly appearance; in a snug corner of the greenhouse it thrives well, although, I must admit, it is not so free in its habit of growth as the majority of the members of this genus.

**Adiantum scabrum.**—Like the preceding, this is a native of Chili, and, like it, it thrives best in a greenhouse. Both should be potted in good rough fibrous peat, adding to it some silver sand and a little chopped Sphagnum Moss, taking care that the drainage is ample and kept in working order; it does not grow so high as the golden-leaved kind, and the pinnules are somewhat larger; they are bright green, sparingly clothed on both sides with a silvery white farinose powder.

#### GYNOGRAMMA.

This genus essentially consists of Gold and Silver Ferns, although some few of its species are not so ornamented. They all require the temperature of a stove; and although I have frequently seen them tried in Wardian Cases, the early days of winter have always closed their career. Some use loam in the soil for these plants; but I have invariably grown them best simply in peat and sand. They like plenty of water at their roots; but they must upon no account be watered over the fronds. During winter they are apt to damp off, and therefore care must be taken that the atmosphere is not too heavily charged with moisture at that season. The following are a few of the most distinct and desirable species and varieties; but almost every batch of seedlings gives rise to varieties, this genus appearing to sport more freely than any other family of exotic Ferns.

**G. chrysophylla.**—This is a broad-leaved massive-looking plant, the pinnules being very obtuse and deep green on the upper side, but below covered with a thick coating of heavy golden coloured powder. The fronds grow from 10 to 20 inches long, and are arched and spreading. It is a native of Jamaica and various parts of the West Indies.

**G. chrysophylla Lauchcana.**—A garden variety of more vigorous growth than the species, producing longer, narrower, and more erect fronds; their upper side is deep green, below profusely covered with golden farina of a somewhat brighter colour than that on *G. chrysophylla*. It is not quite so liable to damp off in the winter as the last-named plant.

**G. chrysophylla Lauchcana gigantea.**—This is even more robust in growth than the preceding; it retains, too, more of the massive breadth of pinnæ, so characteristic of the normal form, and it is densely clothed upon the under-side with a deep rich golden yellow powder. Where a large specimen is desired this variety cannot fail to give satisfaction.

**G. chrysophylla Parsonsii.**—In general appearance this resembles the variety called *Lauchcana*, but it is not so robust in growth, although there seem to be several forms of it, some being taller than others. In addition to its golden appearance, the apex of both pinnæ and frond is ornamented with a beautiful corymbose tassel. It is an exceedingly beautiful garden variety.

**G. L'Herminieri.**—This is a dwarf-growing plant, and, as far as I can ascertain, an extremely rare one. Its fronds usually grow from 6 to 10 inches in length, and are triangular in outline; soft green on the upper side, the under side being clothed with a light, but intensely bright yellow, powder. It requires stove heat, and is found only, as far as I can ascertain, in Guadeloupe.

**G. calomelanos.**—This is a robust growing and comparatively hardy species; its fronds are from 12 to 36 inches long; the bare stem or footstalk being jet black; the pinnules are dark green above and silvery white below, through which (when fertile) the black sori protrude. It comes from the West Indies.

**G. tartarea.**—This is often confounded with the preceding, yet, when seen side by side they are very distinct; the stripes are jet black, whilst the fronds are more massive, with a broader base; they are deep green above, and silvery white beneath. It is a native of tropical America.

**G. pulchella.**—This is a truly beautiful plant, producing fronds from 1 to 2 feet in length, and from 6 to 12 inches in breadth at the base; the fronds are decomposed, the pinnules being cut into very narrow segments, giving the plant an elegant appearance; upper side vivid green, below clothed with a silvery white farinose substance. It is a native of Venezuela.

**G. Pearcei.**—Extremely elegant as *G. pulchella* is, on account of the fineness of its segments, it is surpassed by *G. Pearcei*, which is, however, a somewhat difficult plant to manage. The cool end of a stove seems to suit it best; indeed, if sufficient moisture could be maintained in the greenhouse, I believe it would thrive best in such a temperature. Its fronds are triangular in outline, and four times divided or quadripartite, and from 10 to 18 inches in height; the

pinnæ are cut into segments as fine as the leaves of Fennel, and are vivid green in colour. The under side is dusted with a white powder, but so sparingly is this farina dispersed, that it is not a conspicuous character; the plant itself is, however, so elegant, that it is quite impossible to pass it over in any enumeration of the gems of this genus.

**G. decomposita.**—This is a garden variety of great beauty, and seems to have a better habit and constitution than *G. Pearcei*, from which it is supposed to have sprung, and which, at first sight, it resembles. It, however, differs from that plant in its more spreading decomposed fronds, and in the rather broader segments into which the pinnæ are divided; indeed, in this respect it would seem to be intermediate with *G. pulchella* and *G. Pearcei*. Moreover, the farinose powder with which the under side of the frond and the stipes are dusted, are bright sulphur yellow. It is a very elegant plant, which appears to thrive in a stove temperature.

**G. sulphurea.**—An elegant dwarf-growing plant, which cannot strictly claim to belong to either of the two sections named at the head of these remarks, inasmuch as the farina which clothes the under sides of the fronds is neither gold nor silver, but pale sulphur yellow. The fronds are usually about 6 inches long, but when well grown, I have had them much longer. They are bipinnate, with the pinnæ somewhat distant; upper side light green, but sulphur yellow below. It requires stove heat, and should be grown near the glass. It is a native of Jamaica.

**G. luteo-alba.**—This is a handsome plant with bold fronds and large pinnules, which are dark green on the upper side, whilst below they are clothed with both silver and gold powder. It requires the temperature of a stove, and reproduces itself tolerably true from spores.

**G. peruviana.**—This deserves more general attention than it has hitherto received. It is very handsome when grown into a good specimen; its fronds are broad and spreading—light green above and silvery white beneath. It is a native of Peru, Venezuela, and elsewhere.

**G. peruviana argyrophylla.**—A very handsome variety, having broad spreading fronds, which are beautifully arched, and which measure upwards of 2 feet in length on well-grown specimens. The pinnules are broad and obtuse, profusely clothed above and below with a white farinose powder. Upon no account must this plant be sprinkled with the syringe, for when the fronds become washed, they present a woe-begone appearance; otherwise, it is one of the most beautiful of the silvery section. It was at first distributed under the name of *G. Crossii*.

**G. Wettenhalliana.**—This has every appearance of being a variety of *G. pulchella*. It does not, however, grow so strongly as that kind, whilst the apex of the frond is surmounted by a dense corymb, and the ends of all the pinnæ are prettily tasseled; the upper side is bright green, profusely powdered with white.

**G. Wettenhalliana flava.**—A very handsome variety, resembling the preceding in every respect, except in the colour of its farinose coating, which in this case is sulphur yellow, occasionally suffused with bright yellow.

**G. trifoliata.**—This differs wholly from the other members of the genus, inasmuch as the fronds are tripinnate, the segments being trifoliate and linear. Its fronds vary from 1 to 3 and even 4 feet in height; their upper sides are bright green, while beneath they are clothed with a white farinose substance, or, in some instances, with a bright yellow, and, more rarely, with an admixture of both. It is a very fine plant for the stove Fernery, affording a beautiful contrast with other kinds; but as a pot plant, where space is limited, I do not recommend it. It is a native of Jamaica.

**Onychium auratum.**—An extremely rare Fern, the fronds of which proceed from a creeping rhizome, and attain a height of from 1 to 2 feet; the pinnules are much divided into linear or cuneiform segments. When sterile, the fronds are bright green, but when fertile, the under-side becomes rich golden yellow. It requires a stove temperature. It is a native of the Malay Islands.

#### CHEILANTHES.

The numerous members belonging to this genus are scattered over both the tropical and temperate regions of both hemispheres; they are all extremely handsome and well deserving attention. They should be potted in a mixture of peat and sand, with just a dash of sandy loam amongst it, and the drainage must be good, for although the fronds should not be wetted, they enjoy a liberal supply of water at their roots.

**C. Borsigiana.**—This is really one of the most beautiful little plants in cultivation. It requires cooler treatment than is usually given it, for nearly every one treats it as a stove Fern; I have, however, grown it beautifully in a house with *Odontoglossums*. The fronds of this species grow from 3 to 6 inches high; they have jet black stems and are triangular in shape and tripartite; the upper side is rich

bright green, but that below is clothed with a thick golden yellow farina, with which the black marginal sort forms an elegant contrast. It is a native of Peru.

**C. argentea**.—This forms a lovely companion to that previously named. Its stems are jet black, like polished ebony, and the total height of the plant varies from 3 to 6 inches. Its fronds are triangular in shape, tripartite, and being clothed with a dense coating of white farinose powder, are set off by a continuous marginal line of jet black sori. It should be grown in a snug shady corner of the greenhouse, and not exposed to the sun, as the fronds are apt to curl. It is a native of Siberia, and it has also more recently been found in Japan.

**C. farinosa**.—A fine and handsome Fern, requiring stove heat. It attains a height of from 1 to 2 feet, and forms a handsome massive-looking specimen. The stems are black, the fronds somewhat triangular in general outline, of a deep green above and beautifully silvery beneath, with which the black marginal sori form a pleasing contrast. It is a native of the East Indies.

**C. pulveracea**.—This plant is also known by the name of *Aleuropteris mexicana*. It resembles the preceding species in general outline, but is more dwarf and compact, and the fronds have not such a massive appearance. It is, however, a very elegant plant, usually attaining a height of from 10 to 18 inches. The fronds are triangular in outline and bipinnatifid, the upper side deep green slightly powdered with white, whilst the under side is thickly coated with silvery white. It should be grown in a cool stove. It is a native of Mexico.

#### NOTHOCHLENA.

The species belonging to this genus are widely distributed over the tropical and temperate regions of the globe. As a genus it is distinguished from Cheilanthes by the absence of a marginal indusium. Some of the species about to be enumerated cannot be classed, strictly speaking, with those which have been described, because they have no farinose powder on either surface, but are indebted for their beauty to the clothing of large scales or silky hairs which adorn the under-sides of their fronds.

**N. trichomanoides**.—This is a lovely species for a hanging basket. Its fronds, which are pinnate, droop from 12 to 18 inches in length. The pinnae are roundish or oblong, with crenate edges, dark green on the upper side and white below. This arises from a coating of white stellate scales, over which is scattered some white farinose powder. This variety is prettily margined with black sori. It is a native of Jamaica, and requires stove heat.

**N. rufa**.—Like the preceding this forms a lovely object when grown in a hanging basket in the stove. Its fronds vary from about 1 to 2 feet in height; they are pinnate, the pinnae being deeply notched, the upper side light bright green, the lower clothed with pure white woolly scales. This charming plant is a native of Mexico and Peru.

**N. nivea**.—An elegant dwarf-growing plant, forming tripinnate fronds, some 10 or 15 inches high, the stipes being slender and jet black. The pinnae are roundish, bright green on the upper side, and clothed with white farinose powder below, through which the naked black sori protrude. It is a compact-growing plant of great beauty, and requires stove heat. It is a native of tropical America.

**N. Hookeri**.—This is an extremely rare plant, and as far as my experience with it goes, rather smaller in growth than the preceding. It is distinguished by a white farinose powder being distributed over both surfaces, rendering it very effective and distinct. It requires stove heat, and must by no means be watered overhead.

**N. flavens**.—When this first appeared in collections it was named *N. chrysophylla*. The plant, however, to which this latter name really belongs, is totally different from it in appearance, and is still a desideratum. *N. flavens* is a most elegant Fern; its stems are very slender and black as polished ebony; the fronds are tripinnate, growing from 6 to 10 inches high, or perhaps a little more. The pinnales are small and round; the upper side intense bright green, below thickly coated with a bright golden farinose powder, through which (when the fronds are fertile) the jet black naked sori protrude. It is a lovely object for a small stove, and should find a place in every collection of Ferns throughout the country. It is a native of tropical America.

**N. lævis**.—This is an extremely handsome cool house Fern, of compact habit, and when well grown forming a nice specimen. The fronds attain a height of from 12 to 18 inches, and are pinnate; pinnae entire, roundish, the upper side deep green, below clothed with long white woolly scales, which, as the fronds attain age, change to a russet brown, the effect of the three colours being very pleasing. It merits a place in every Fernery. It is a native of Mexico.

**N. sinuata**.—According to some, this is merely a variety of the above, but, whether species or variety, it is so thoroughly distinct, and reproduces itself so truly from spores, that it would be injudi-

cious not to have a different name for it in a cultivated state. Its fronds are from 1 to 2 feet in length, and pinnate; pinnae broad and deeply lobed at the margins, the upper side deep green, the reverse being thickly coated with long white woolly scales. It requires to be grown in a cool stove. It is a native of Mexico.

**N. lanuginosa**.—A superb greenhouse species, the fronds of which attain a height of about 6 inches, sometimes a little more; they are bipinnate, divided into small segments, and dark green on the upper surface, the under side being furnished with a dense coating of long silvery-white wool. This is indeed a charming plant, which must not be allowed to get dry, or the fronds will curl completely up, neither should it be watered over-head. It is a native of the Madeira Islands.

**N. canariensis**.—This is a grand plant for the greenhouse Fernery, but it must not be watered over the fronds. If well cared for, its leaves attain a height of nearly 2 feet. They are ovate lanceolate in shape, and bipinnate; the pinnales being entire and obtuse, the upper side deep green, the under side densely covered with large and long scales, which, however, are neither the colour of gold nor silver, but resemble a baser metal, being of a bright coppery red. It is a native of the Canary Islands.

**N. Eckloniana**.—An extremely rare plant in cultivation. It is usually coddled up in the stove, but it thrives best in the greenhouse, in a sunny corner. The fronds attain a height of from 6 to 12 inches; they are ovate in shape and tripinnate, the upper side is deep green, but the under side is clothed with a dense covering of white silky-looking hairs and scales; on old fronds these change to light brown. It is a native of South Africa.

**N. Marantæ**.—This is an exceedingly pretty plant, which seems nearly allied to *N. canariensis*. It has proved itself to be perfectly hardy in dry, snug crevices of rock-work, and forms a beautiful specimen in the cool Fernery; the fronds are broadly lanceolate, from 6 to 10 inches high, bipinnate; the pinnales linear, and somewhat obtuse, dark green above, but thickly clothed on the under side with large coppery-red, imbricating scales. It is a native of Northern Italy.

**Nipholobolus bicolor**.—The whole of the species belonging to this genus are remarkable for the peculiar and dense coating of stellate scales on the under side of their fronds. This species, however, is the only one which I can include in the present article. The fronds are produced from a creeping rhizome, and seldom exceed a few inches in height; they are simple, entire, and somewhat spatulate in shape, dark green on the upper side, but clothed below with a thick coat of silvery-white stellate scales. It is a distinct and handsome little greenhouse plant, admirably adapted for planting in a small basket in a Wardian case. It is a native of New Zealand.

**Cyathea dealbata**.—This is a member of an extensive genus of Tree Ferns; indeed, with age, it attains a height of nearly 20 feet, the largest which I have seen in this country being about 12 feet. This fact, however, need by no means deter amateurs from growing it, for if a young seedling plant is obtained it may be grown into a handsome specimen, and it will be many years ere it becomes too large for an ordinary-sized Fernery. The fronds are tripinnate and pinnae-like, deep green on the upper side and clear silvery white below. It is a magnificent plant, which thrives in a greenhouse temperature, and should be potted in a compost consisting of two parts peat, one part loam, and one of sand. It is a native of New Zealand.—*The Farmer*.

#### VERONICAS AS DECORATIVE PLANTS.

VERONICAS, of which *Andersonii* and *speciosa* may be taken as the types, are amongst the most useful of plants either for conservatory decoration or in the shape of small plants for drawing-room stands. I do not say they throw off as much colour as a mass of scarlet zonal Pelargoniums or bright-coloured Chrysanthemums in autumn, but Veronicas, of the *Andersonii* section, furnish a colour that is comparatively scarce, at least in proportion to other shades. Amongst the best varieties may be named Imperial Blue, Madame Boncharet, hybrida, and Violaera. The cultivation of Veronicas in pots is so simple and easy, that it is scarcely necessary to enter much into detail respecting it. Cuttings made of the ends of the young shoots strike freely in a hotbed in spring; they should then be potted off and grown on for a time, according to the usual practice with greenhouse soft-wooded plants, pinching in all strong shoots to induce a bushy habit. It is best not to overpot them. Nice plants for autumn blooming may be grown in 6 and 8-inch pots, putting, of course, the strongest plants into the largest pots. They should be potted finally into the sized pots just named by

the end of July, and should be plunged in a cool ash-bed in the open air; they should be well watered, and should receive occasionally a soaking of weak liquid manure. They must be housed before frost sets in, *i.e.*, some time early in October; they will then flower freely all through the autumn and early winter months.

If large plants are required the second year in early spring, shorten back all long shoots to put the plants into shape, and after the buds have broken, repot them and grow them on to any size the cultivator wishes. I once had a plant of *Andersonii* planted out in a conservatory border, a perfect pyramid, more than 8 feet high, and it was rare indeed to see it without flowers at any season of the year; it must, however, occupy a light part of the house and not be overhung too much with creepers. As regards soil the *Veronicas* are not at all particular. A rather sandy loam, slightly enriched with thoroughly decomposed manure, suits them well. As a rule, old plants should have rather a richer compost than young ones. Any old plants that are not required for pot culture may be planted out in the border in the open air. And very effective they are in mixed beds or borders, producing freely their long spikes of ever changing flowers till frost sets in in the autumn, when, if it is desired to save them, they may be lifted and potted, and if the operation is carefully performed, they will continue blooming in a cool light house all through the autumn. The creamy white foliage of the variegated variety of *Andersonii* makes it a very effective foliage bedding-plant.

E. HOBDAY.

**Hot-water Pipe Jointing.**—I put up a greenhouse three years ago, 32 feet long, and heated it with hot-water pipes, and a tubular boiler, with a 2-inch outlet into 4-inch pipes. All the joints of the pipes split, and I want to know if the small connections at the boiler are the cause of the splitting, or whether it is attributable to bad piping, some of which has cracked in two or three places across the collar and leaks badly.—W. W. [The cause of your pipes splitting at the joints is probably owing to the cement being mixed for wrought instead of for cast iron, and too large a quantity of ammonia being used. Cement for cast iron joints requires but a very small quantity of ammonia, and must not be caulked too tightly.]

**Exposing Greenhouse Plants in Summer.**—It is a common practice to set greenhouse plants out of doors in summer, the impression being that they are benefited by such treatment; and so they are, provided the pots are not exposed to the sun. The youngest and most tender roots are always next the pot, consequently they are the most liable to injury from any sudden check, occasioned by the sun drawing the moisture out of the pot, and, therefore also out of the soil. It is no uncommon thing, indeed, to see the soil quite shrunk away from the pot, and when water is supplied, it escapes by the outside of the ball, and the soil inside is not wetted in the least. Plants placed under such conditions cannot be expected to succeed. If plants must be turned out of doors, they ought always to be plunged in some porous substance; although, at the same time, it ought to be something that will hold moisture; for instance, cocconut fibre, very rough peat, Moss, or sawdust. I have seen sand used, but it holds the wet too much. The pots should always be placed on slates, or some other material that will prevent worms from entering them. The plants should also be shaded from the sun and protected from heavy rains. By following the above plan, a great deal of time will be saved in watering, and the plants will present a natural and healthy appearance.—A.

## NOTES AND QUESTIONS ON THE INDOOR GARDEN.

**Cypripedium barbatum grandiflorum.**—Comte F. Du Buisson, in a letter to the *Flora des Serres*, states that his experience of this plant has been such as to warrant its cultivation in a cool house with complete success. He has grown it in his Camellia-house, suspended from the roof in a basket containing a compost of peat-soil and charcoal, surfaced with live sphagnum. In the winter the temperature of this house ranged from 39° to 45° Fahr., but, notwithstanding this, and also that the plant was kept rather dry, it continued to push vigorously, and, by Midsummer, showed three fine flowers. When placed in a warm house, it comes into flower about the end of April, and this earlier blooming is, in the Comte's opinion, the only advantage which that mode of culture presents.

**Bossiaa tinophylla.**—I have two large specimens of this in a cool conservatory, and they are now, and have been for the last three weeks, completely laden with bloom. They resemble *Aetis gracilina* both in flower and habit, and are grown in pots in a mixture of rich yellow loam and leaf-soil. Each pot stands near a trellised pillar, to which the shoots are tied to a height of 5ft. or 6ft. and their ends are permitted to hang down in graceful festoons. They need no other care than shifting every one or two years, watering freely whilst they are growing and flowering, and rather sparingly in winter. Under this treatment, and merely protecting them from frost, they annually grow freely and bloom most profusely.—JAMES FORBES, Perth.

## GARDEN DESIGN.

### THE AVENUE GARDENS IN THE REGENT'S PARK.

THESE, made some years ago by Mr. Nesfield, are now among the most popular and attractive gardens in the public parks of the metropolis, and are, especially at this season, tastefully embellished with flowers and ornamental-leaved plants. There is a good deal to admire in these avenue gardens, considered as such, and from the point of view of design. The whole is so disposed that there is not an overpowering display of colour in any one place. The circular and oval beds north and south of the central gardens are well relieved by the surrounding vegetation, and even in the parts more especially laid out as a flower garden proper, successful attempts are made to relieve the ordinary bedding flowers by more stately and graceful vegetation. The way in which *Yucca recurva* is used and grows here should be noticed by all interested in flower gardening. In summer *Canuas* are also very artistically used here, and sometimes we have seen them mixed with the large-growing *Dallias* with excellent effect. Let it be observed that the parallelism, by some considered so orthodox in geometrical gardening, is not here carried out. One side does *not* "just reflect the other." The garden is, in fact, a very appropriate one for the position, assuming that the avenue and its surroundings will remain as they are. But it is very likely that this will not be the case. The avenue offers the finest opportunity for improvements of any city site in Europe. The Champs Elysees would prove nothing to what might be formed in the Regent's Park by opening up the avenue as far as Portland Place. When that is done a very much broader and more dignified plan than the present must be adopted. It is much to be regretted that such a noble site as the upper part of the avenue should be in such a mean and unworthy condition as it is at present.

## THE GARDEN GUIDE.

### SUFFOLK.

#### COLDHAM HALL.

THIS fine old mansion stands on an eminence at the outer edge of a small park, and commands splendid views of the surrounding country. The old-world look which the hall has is not removed when one drives round it and enters the small garden that surrounds the back and one side of it. This is in the mixed style—vegetables, flowers, and a little glass being all crowded pretty closely together. Coldham forms a prominent feature for miles in the surrounding landscape, and has played rather an important part in history; it hardly, however, deserves naming in a horticultural point of view.

#### CHADACRE HALL.

This is a fine modern building, forming in that respect a striking contrast to Coldham. It is placed in a beautifully undulated park of about 100 acres. The river Chad meanders through the bottom of the valley, and advantage has been taken of that streamlet to form several pieces of ornamental water, one of which covers several acres of ground within sight of the mansion. One of the lakes has a prettily winding margin, and contains an island planted with Pampas Grass, Salices, &c. The house is surrounded by a pretty flower garden and some beds of shrubs. There are also a good kitchen garden, extensive shrubberies, some fine Coniferae, an interesting Fernery formed of rocks, a small flower garden by the river, several good Vineries and plant houses, a nice conservatory containing Orange trees, a north Fernery under glass, greenhouse, &c. A very fine American Aloe flowered in the conservatory here last year, and another almost the same age and size may "show" at any moment. Roses and most shrubs and trees do well in the strong soil of Chadacre. The site is admirably adapted for a series of terrace gardens reaching from the house to the rivulet; as it is, the garden is a medley of beauty, a mixture of all styles, in which the mixed shrubby and trees and herbaceous plants predominate. A good many Wellingtonias and other choice Coniferae have been planted in the park and in the belts surrounding it.—Miss Hallifax; gardener, Mr. Foulger. 7½ miles from Sudbury, 4½ miles from Lavenham, 8 miles from Bury St. Edmunds.

#### BOXTED HALL.

This is a fine old brick mansion, surrounded by a moat and approached by a bridge. In front of the house the park rises

abruptly. A river sweeps by at the back of the house and feeds the moat, and on the other side of it are the kitchen gardens and small pleasure grounds. In the shrubberies are a small Fernery and root garden. The house is situated on the water line, with the ground rising on each side of it. The small rivulet just alluded to sweeps away through woods, where it widens out into sundry lakes. These are clothed with Reeds and water Lilies. In addition to these, a magnificent collection of aquatics might readily be grown at Boxted—the position being sheltered and warm. The kitchen garden, though so near the water line, is fruitful, and contains some nice Vineries and several other glass houses. Peaches do well on the walls, which are well furnished. A good many young Coniferae have been planted of late years about the pleasure grounds and belts surrounding the park. The latter contains about 100 acres, and is well wooded and interesting.—Mrs. Poley; gardener, Mr. H. Foreman. Six miles east of Clare, and 7½ N.N.W. of Sudbury.

KENTWELL HALL.

This is a fine old mansion, surrounded by a moat, and approached from Melford through a dense, dark, lofty avenue of Limes about a mile in length; narrow, but cool and delightfully refreshing in the hottest day of summer. The house has a quaint, old-world look about it, that gives it special interest. The gardens and pleasure grounds disappoint one whose hopes have been excited by the delightful avenue just alluded to. They are small, and fairly kept; but bear no proportion either to the fine avenue of Limes or the large and richly-wooded park which bounds the public road for more than a mile beyond the village of Long Melford.—E. S. Bence, Esq. Thirteen miles from Bury St. Edmunds, three miles north-east of Sudbury.

MELFORD HALL.

This is a fine old Elizabethan mansion, which has evidently been surrounded by a moat at a recent period; two sides of the gardens are still surrounded by water, the moat having been evidently filled in on the other two sides. The boundary wall of the pleasure grounds and kitchen garden is carried along near to the public street, but is separated from it by the water of the moat inside. This wall, and, indeed, several others, have long been famous for the excellence of their Pear trees, and fruit generally. The pleasure grounds around the house are pretty, and well furnished and kept. A nice lawn, groups of flower beds, mixed borders of shrubs and flowers, and pretty walks lead in different directions towards the kitchen garden, which adjoins the pleasure grounds. The kitchen garden here has recently been remodelled and very much improved, and produces excellent crops of fruits and vegetables. On the east side of the garden a small rivulet expands into a lake, full of reeds, &c., and here almost at the water line the Vineries and other glass houses are placed. The position is a cold and a wet one, though pretty good Grapes are usually grown here. The slopes of turf round the hall are very pretty, and the chief windows command fine views of the park, which is large and well wooded, while the pleasure grounds and shrubbery belts, &c., are so disposed as to shut out the village entirely from the windows. The entrance gate from the main street is quite in character with the age and style of the building.—Sir

The Avenue Gardens in Regent's Park.

William Parker; gardener, Mr. James Galbraith; three miles from Sudbury, seven miles east of Clare, and thirteen miles east of Bury St. Edmunds.

**Protection of Pollen.**—Dr. A. Kerner reprints from the "*Proceedings of the Medical and Scientific Society of Innsbruck*" an interesting memoir on this subject. Pollen is of two kinds, powdery and coherent. The former kind is found almost exclusively in those plants whose fertilisation is effected by the agency of the wind. The quantity of pollen is in these cases enormous; the anthers are frequently attached very slightly to the end of elongated filaments, so that the pollen is shaken out of them by the least breath of wind; the flowers grow on the most exposed parts of the plants, frequently appearing before the leaves, so as to give greater facility for the dispersion of the pollen, and are not provided with brightly coloured corolla, powerful scent, or nectar, for the purpose of attracting insects. Plants, on the other hand, whose pollen is coherent, are dependent on insect agency for its dispersion and transport to the stigma. It is therefore absolutely essential in these cases that some means should be provided for its protection from moisture, whether rain or dew, which would immediately destroy its efficacy, until such time as it may be carried away by insects. A variety of contrivances are actually found in nature for effecting this end, which may be classified under the following heads:—1. Protection by portions of the pistil or stamens themselves, as in the petaloid stigmas of Iris. 2. By portions of the calyx and corolla; this occurs in an immense variety of forms. 3. By sheaths, bracts, or foliage-leaves. 4. By periodic movements of the leaves of the perianth, as in the closing of flowers at night or in rainy weather. 5. By curvature of the axis, as in those numerous flowers the opening of which is always turned towards the ground at the period when fertilisation takes place. From the examples adduced Kerner draws the general conclusion that the protection of the pollen against the injurious effect of premature moisture is the more perfect the smaller the number of flowers and of pollen-grains in the individual, the greater their degree of coherence, and the more exclusively the flower is fertilised by insect agency. In those plants where the flowering extends over a great space of time, where the anthers in the same flower vary in the period of their dehiscence to allow the escape of the pollen, and where the number of flowers in an inflorescence is very large, the protection of the pollen against the influence of the weather is reduced to a minimum, as in Umbelliferae and many species of Cruciferae and Saxifraga. Finally Kerner draws the conclusion that those plants whose coherent pollen renders insect agency necessary for their fertilisation can only have existed in very recent geological periods; and those new species or varieties must necessarily have the advantage, and tend to become perpetuated, which possess superior advantages, in respect to the climate in which they grow, for the protection of their pollen from all injurious influences. The plants, the remains of which are found in the oldest geological formations, are generally of that class which do not require insect agency for their fertilisation.

## THE FLOWER GARDEN.

### THE PENTSTEMON.

Of all our hardy garden flowers, there is scarcely one that has been so rapidly and largely improved as the strong, free-blooming Pentstemon. In the hands of hybridisers and cross-breeders, working patiently in the direction of certain definite results, in so far as the processes of nature can be controlled, this favourite hardy flower has come to be associated with a wealth of forms and a flush of hues remarkable in character and extent. A selection of say twenty varieties of Pentstemons, or a bed of seedlings raised from a good strain, will yield colour ranging through many intermediate shades and tints, from pure white to dark red and black purple. Easily managed, and flowering most profusely through many weeks of the summer, the Pentstemon is well adapted for culture by all who are lovers of flowers. Standing singly in the mixed border, or cultivated in beds, it is always an object of considerable interest, while it supplies an abundance of cut flowers when needed. As it is well that anyone setting himself to cultivate the Pentstemon for the first time should start well, I would recommend that a few distinct and leading varieties of known excellence be selected, in order to lay the foundation of the floral superstructure. Such varieties as Albert Tardieu, Arthur McHardy, Bons Villageois, Bridesmaid, Candidate, George Sand, James Rothschild, Lady Stanley, Léontine du Louet, Mrs. A. Sterry, Regalia, and Sophie should be obtained; and if these were had from a nursery at once they should be nice, bushy, well-established plants, in large 60 pots. There is nothing like a bed to set forth the beauty of the flowers; for it is by having leading varieties in association that one comes to understand something of the nice differences that distinguish varieties—differences that are not marked by the casual observer, but which are clearly made apparent to the painstaking, observant cultivator. It is in noting such differences, in watching the gradual unfolding of the petals of new varieties, and in appreciating the presence of a new shade of colour, that much of the poetry of the cultivation of flowers consists. A good yellow loam, not too light, enriched by the addition of some manure and leaf-mould, suits the Pentstemon exactly. In a bed composed of such a soil the grower should plant his Pentstemons fully eighteen inches apart each way, so as to afford space for the free growth of the plants. When the plants are turned out of pots a stake should be placed against each, to support the leading shoot, and water should be given, if the weather prove dry, till the plants become established in the ground. After that the task is a very easy one, and a rich harvest of floral effect will be certain to result. Such varieties as it may be deemed well to preserve should be propagated by cuttings taken in August and September from the young growth that springs up round the base of the flowering spike. If these cuttings be put into store-pits, and placed on a cool shady shelf in a greenhouse, or in a cool frame, they will soon root, and in October or November they may be potted off into small 60 pots and wintered in a cold frame or any handy place. The roots can also be divided in the autumn, but by far the best plants come from cuttings. The crowns will continue to flower for two or three years or more; but the flowers become deteriorated, which is an additional reason for propagating annually by means of cuttings. Then a few seedlings should be raised annually. The seed should be taken from the finest and most distinct varieties; and, if the cultivator has a little bottom heat at his service early in the spring, he may postpone sowing his seed till the early days of February; it can then be thinly sown in pots or pans, and, as soon as the plants are large enough to handle, they may be potted off into thumb-pots, and grown on, and gradually hardened off by the end of April. In cases where the cultivator has no bottom heat in reserve, it will be best to sow the seed as soon as ripe in a shallow box, and winter it in a cool frame or greenhouse—the plants to be potted off into thumb-pots as soon after Christmas as possible. The inferior flowers—relatively inferior as compared with some of the best-named varieties grown—should be relegated to the shrubby border, where they will be very useful as decorative subjects during the summer. The superior varieties can take the place in the bed of any that may be so removed.

R. D.

### LOBELIA PUMILA GRANDIFLORA.

AMONGST Lobelias this is a little gem, but it does not come true from seed—at least with me seedlings of it have always proved unreliable. A large stock of it may, however, be worked up from a few plants in spring, as the smallest bits root quickly. Perhaps the most expeditious way of getting up a large stock of it is to pull the little tufts into very small bits, when each little bit will separate readily, with a root or two attached to it, and may be dibbled into boxes, about two inches apart, and the boxes afterwards placed in a

close pit; and, as it rapidly establishes itself, if the stock is deficient the same process may be gone through again and again till the requisite number is obtained. In the final planting out in the beds it is bad policy to plant out large plants. It grows so close and tufty if large plants are put out, especially if they have been grown in pots and are at all pot-bound, that the damp will lodge in the hearts of the plants and destroy them, and failures and blanks have arisen from this cause alone. Last year I turned out several thousands of this Lobelia, and at planting time, as the plants were rather larger than desirable, each plant was pulled into three or four pieces, and planted about 5 inches apart, and they did admirably under this treatment. There is also a further disadvantage in planting out large plants of this Lobelia. Every plant in a general way makes roots in proportion to its branches and foliage; and in this case, where the growth is close and dense, and roots do not wander far away, the little spot of soil where each plant stands is soon densely occupied with roots, and the available food consumed. Before the end of the summer there is a lack of nutriment, and the plants, instead of bringing forth a succession of their beautiful azure blue flowers, commence ripening seed, and consequently their beauty declines prematurely. But if small plants are used, and planted rather closer together, the plants thoroughly establish themselves, and the beds will be furnished quite as soon. The whole of the soil is occupied with roots, but not so densely in any one spot; the store of food provided for them is more easily available and the supply lasts longer, and the beauty of the beds is consequently prolonged, a remark which applies also in a greater or less degree to many other plants commonly used for bedding out. It is a great mistake to plant out long straggling plants of Verbenas, Petunias, &c., although some prefer those kinds of plants, because they may perhaps have a flower or two at the points of their long shoots; but smaller, bushy, sturdy plants are the best for lasting effect. There are many combinations in which these dwarf Lobelias might be brought into prominence in every garden. Good really blue bedding plants are scarce in proportion to scarlets and yellows, as there are many yellow-foliaged plants that are now largely used, and notably I may mention the golden Pyrethrum—one of the most useful plants of recent introduction to the modern flower gardener. One of the prettiest combinations in which this Lobelia looks conspicuous is in the form of a ribbon border. The front row may consist of *Santolina incana*, clipped in close, so as to resemble a neat low stone edging. This plant is better adapted for this purpose than *Cerastium tomentosum*; its growth is more compact, and less troublesome to keep right. The second and third rows should be Golden Fleece Geraniums and *Lobelia pumila grandiflora*, planted alternately. In the fourth and fifth rows I place *Iresine Lindlei* and variegated Geranium, Lady Plymouth, or Flower of Spring. I think I need not fill in the back of the border, as that might be varied according to taste; but the front planted in the way I have stated certainly looked very pretty, as the dwarf tufts of Lobelia set in amongst the golden leaves of the Geranium, which exactly matched it for height, make one of the most pleasing combinations of the kind I have seen. I believe some have found a difficulty in wintering this Lobelia. We wintered our stock last winter in a cool house on a shelf near the glass, but kept comparatively dry, with a free ventilation. But it is of some importance to have the plants for stock taken up and established in September. We always take up a few healthy plants that have been put out for the purpose, pull them to pieces, at the same time cutting off any flowering growth, and pot them into 3-inch pots; and in these pots they are kept till the beginning of March, when the work of their propagation begins. Damp is the chief enemy to guard against, and it can be most easily met in the way I have indicated, by keeping the plants close to the glass, with a free circulation of air at all times when the weather is favourable.—E. Hobday.

### A SMALL OUTDOOR FERNERY.

THERE are few small gardens where an opportunity does not exist for the making of a picturesque hardy Fernery. Often, if there is no better place, the rubbish-hole or nook may be turned to good account. If there be nothing else, a space behind the bushes, and between them and the boundary wall, will be found useful. Send a little walk by one of the larger bushes into one of these unseen places; make a tiny winding valley, letting the walk through it emerge at another convenient point. The main point I wish to show by my sketch is, that in this tiny vale a good effect may be obtained without resorting to the masses of brick-rubbish, &c., that one sees in so many gardens. Steep flanks of impossible rock are by no means necessary for Ferns; on the contrary, they do not

thrive so well on such structures as in such a place as is here represented. They are, indeed, perfectly at home on lowish banks, if the soil be suitable, and there are enough rocks and stones used to keep the ground moist where needful. A more picturesque effect is secured by a few well-chosen half-buried stones than by the quantities of ill-chosen or ugly ones that are so frequently used. Indeed, if the choice lies between the common style of rocky Fernery and the level ground, it is much better to choose the latter. In the hardy Fernery, it is too much the fashion to plant Ferns alone, as if they only enjoyed such a position. There are many lovely hardy flowers which are wood-haunters and shade-lovers as well as Ferns, and by planting these among the Ferns, a much more interesting result, and a much higher beauty, are produced, than if we only plant Ferns. Such noble plants as *Cypripedium spectabile* and *Trillium grandiflorum* thrive better in the moist free soil and the partial shade suited for Ferns than in ordinary borders. Saxifrages, Primroses, Lily

Peep at a small hardy Fernery.

of the Valley, Snowflakes, and hardy Cyclamens are a few of many plants that will associate beautifully with Ferns, and that will lend a high degree of interest at all seasons to this miniature garden.

A. D.

#### DELPHINIUM NUDICAULE ELATIUS.

THE *Delphinium nudicaule* has now been sufficiently long before the horticultural world to allow of its value being impartially estimated, and I am, therefore, well content to leave it to stand or fall by its own merits. I am desirous, however, with your permission, of drawing attention to a distinct variety of this plant, which is at present but little if at all known, and which will prove, I think, a great acquisition.

The form first introduced by me was, as is well known, comparatively dwarf in habit, for although a taller variety was raised about the same time, and may have been accidentally distributed when not in bloom, it was for the moment considered inferior to the other, and was consequently kept in hand. Further acquaintance with this variety has led, however, to the conclusion that it fully equals the dwarfer form already distributed in its effectiveness as an ornamental plant, whilst it possesses merits peculiar to itself. The most apparent distinctions consist, doubtless, in its taller virgate stem, pyramidal habit, and greatly elongated panicle of flowers; the former not seldom reaching a height of three feet, of which nearly two are occupied by the inflorescence. There are, however, several other important, if less obvious, differences, of which the most striking is in the character of the tubers. These, in the dwarf form, are so comparatively small that they might almost be covered by a wine-glass, and very rarely exceed two inches in length. But in the plant under consideration, they are often from five to eight inches long, and in some instances this is exceeded, the tubers of each fascicle diverging considerably. It is, I think, a hardier plant, and, what is of even greater importance, of much longer duration—being, in fact, as far as three years' cultivation can enable one to judge, a real perennial, increasing in size and vigour year by year, and capable of increase by division at the root, to a certain extent, when sufficiently strong. This can hardly be said of the dwarfer

form, which requires to be frequently renewed by seed, and does not bloom vigorously after the third season. On the other hand, the individual blossoms of *Delphinium nudicaule elatius* are sometimes slightly smaller than in the dwarf form; but this is compensated for by their much greater number, which ensures a longer period of bloom. There is, indeed, a distinct character about the flowers of each variety, those of the dwarf form being shorter, with a thicker curved spur; those of the latter one having a longer, straighter, and more slender spur, and a more open mouth, with projected petals. It is also noteworthy that *elatius* produces with me but few seeds; but they are more than twice as large as those of the dwarfer plant. In both varieties there is the same tendency to variation in the forms and tints of the foliage, and in the shades of colour in the flowers. A group of about half a dozen plants produces a really splendid—I may almost say unique—effect, and few things would be finer than a small bed of the *elatius*, encircled by a ring of the *Aquilegia glandulosa*, var. *juvunda*, which blooms at the same time, and is of dwarfer habit than the other forms. The *Delphinium* has been in bloom from the end of April to the present time, and many of them are still very attractive. The distinctive appellation "*elatius*" has been adopted at the suggestion of Dr. Asa Gray, who, as long ago as 1840, in the supplement to Volume I. of "*Flora of North America*," recognised the existence of two distinct forms of this plant.

Before quitting the subject, as the description given of *D. nudicaule elatius* may suggest to some readers the possibility of its being identical with the *D. cardinale* (Hooker), I am able to state with confidence that the two plants are quite distinct, though closely related. It is now about 20 years since I first cultivated the *D. cardinale*, when introduced by Messrs. Veitch, but speedily lost it, and my recollections are necessarily somewhat imperfect. I have, however, recently raised a few plants, one of which is about to flower. The character of the foliage alone would suffice to distinguish it from either of the forms of *D. nudicaule*, the leaves being very deeply divided, with very narrow distant segments, especially those near the summit. I believe that when the plant expands its blossoms, ample differences will be apparent, but, however that may be, there is one unmistakable and very interesting distinction between the two plants, in the manner in which the seeds germinate. In both forms of *D. nudicaule*, the two cotyledons are invariably connate, so that the plumule appears to emerge laterally from the soil. In *D. cardinale* the cotyledons are perfectly distinct, and the plumule rises in the ordinary way from their midst.

Ipswich.

W. THOMPSON.

#### THE DRACÆNA AS A BEDDING PLANT.

AFTER four years' trial of *Dracæna grandis*, *terminalis*, and *Cooperii* out of doors during the summer months, in one of the most unfavourable parts of Yorkshire, I think we are justified in recommending these three varieties as a very desirable addition to the sub-tropical group. We have had them out from June to October, and find that they not only retain their foliage and colour well, but even grow a little; though we wish it to be understood that they ought to be grown to the desired size before they are put out. Anyone who has seen those varieties of the *Dracæna* knows how ornamental they are, and can conceive what a gorgeous group they make when a number of plants are massed together. Of course it is not everyone who can get up and keep stock of such plants in quantity sufficient to fill whole beds, though this might be done in plenty of places without difficulty; but it is not at all a difficult matter to get up as many plants as will lend character to a bed, planted perhaps with such things as Cannas, Phormiums, or Palms—plants which are rather dull by themselves, but when lighted up with *Dracænas*, if only round the margin of the bed, the improvement and effect are telling. I am aware that the *Dracæna* has been used for some years in the south as a sub-tropical bedder; but I am recommending it now for more general use in any part of England or Scotland, where the climate is ordinarily favourable, and I dare say a few hints as to the most expeditious way of getting up a stock of plants will not be unacceptable. Those who have an old plant or two have the means of getting into a stock at once, and they should lose no time in doing so. A common but not an expeditious way of propagating it is to

make cuttings of the tops; the next best way is to split the stem up, chop it into pieces, and plant them like Potato sets. Many of these will make buds, and before long plants, and every piece should be utilised to help to add to the stock; but the surest way of multiplying them is to cut up those tubercular protuberances that form themselves on the roots of the *Dracæna*, particularly on old plants. If these are cut into pieces about a quarter of an inch long, taking care always to leave as much of the outer bark on each piece as possible, and laid in a pot among fine light soil, just covered deep enough to prevent their being washed bare in watering, and plunged in a bottom heat of 90°, you will very soon have about as many nice plants as you had sets. Once the plants are fairly up and rooted, they must be potted singly in 4-inch or 5-inch pots, in a compost of loam and leaf-mould, and grown on in a moist stove temperature, where they can have a good light, so as to bring the colours of the foliage well out. By midsummer, autumn-struck plants will be a good size, and after being hardened a bit in a cold house they may be plunged out of doors, where they are intended to be for the summer. If tall, conspicuous plants are desired, they should be grown on for two years or more; and if a stock is propagated every year, there will always be a good supply for all purposes. We find the *Dracæna* to be just about as hardy as the *Cauna*, having had them planted out together. J. S.

**Daisies for Edgings.**—No one knows how useful all coloured Daisies are for the above purpose, unless they have tried their effect, and having done so myself, I can recommend them with confidence; and to those who like permanent edgings, they will be found invaluable. How well a bed edged with pink Daisies shows up beside one done with *Viola lutea*, or the white against *Viola cornuta*, and, again, the deep scarlet next to white *Arabis*. Besides blending well with other colours, the Daisy has many other important advantages—it is very hardy, will stand well any kind of weather, is easily propagated by dividing the roots in autumn, and can be bought for a very small sum. It comes in flower very early in the spring, and remains so nearly all through the summer, so that it is useful for the spring as well as the summer bedding. Its dwarf and compact habit of growth makes it very useful where there is spring bedding done in the carpet style. I had two small circular beds myself this spring, in which Daisies were employed, one being a cross of scarlet on a groundwork of golden *Pyrethrum*, and the other in the same form, only pink Daisies and variegated *Arabis* had been used. These little plants are not particular as to soil, provided it is not very dry, so if they have to be planted in that kind of ground during the summer months, they must be kept well watered should the season prove a dry one. There is a variegated (golden) kind, with scarlet flowers, which is effective when in or out of bloom, but this is not so common nor so cheap as the others above mentioned.—A. H., in "*Gardener's Record*."

#### NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Hedychium Gardnerianum.**—This fine old plant, often grown in stoves and warm houses, grows vigorously and flowers well planted out in a greenhouse which is merely protected from frost.—R.

**Floral Wall Copings.**—In reference to your correspondent's article on this subject (see p. 433), I bear to say that I made, and exhibited at the International Exhibition of 1871, among other objects in terra cotta, what I called "Alpine coping for garden walls." It was made to hold soil enough for such plants, and, as a coping, it was cheaper than common stone.—JAS. PULHAM, *Broxbourne*.

**Oriental Poppy.**—Among herbaceous perennials now in or coming into blossom, none surpass in size of flower, brilliancy of colour, and freedom of bloom, the Oriental Poppy (*Papaver orientale*). It makes a capital border plant. There are several varieties of it, the best being *Papaver bracteatum*, which is very distinct, and has larger flowers, of a deep crimson colour, than those of the other kinds. Fine plants of *P. bracteatum* may now be seen at Kew, and likewise several other forms of this species.

**Wanner's Harebell (*Campanula Wanneri*).**—Of all the dwarf species of Harebell, this is, so far as I have seen, one of the best. Its flowers are tubular, about 1½ inch long, and of a fine purplish blue colour. They are, in fact, large for the size of the plant, which grows only a few inches in height. It forms a charming rock plant, associated with such dwarf *Campanulas* as *pulla*, *pusilla*, *caespitosa*, &c., and, when more common, will doubtless often find a place in the front of mixed borders. It is now in flower on the rockwork at Kew.—T. S.

**Viola umbrosa (Fries).**—This is a pretty dwarf species, found in the north-eastern part of the Russian Government of Suolensko, only in half-shady positions, on the banks of streams. It grows about 2 inches high, and commences to bloom in the open air in May, the flowers being of a delicate lilac colour, shaded with rose. When grown in a cool house, it will flower in February and March. It does not appear to be a good kind for forcing, as the delicate tints of the flowers are much impaired by the process; but it succeeds perfectly in ordinary soil in a half-shady, moist position, in which its charming little flowers attain their greatest beauty.

## THE GARDENS OF ENGLAND.

### BLENHEIM.

THE palace of Blenheim and the magnificent park were the munificent gift of the English nation to John Churehill, first Duke of Marlborough, in recognition of a series of almost unparalleled victories, by which the reputation of the British arms was carried to the highest pitch. The gift was worthy of the nation. It comprised nearly the whole of the royal domain of Woodstock—that ancient regal seat which was the scene of the half-legendary story of "Fair Rosamond." The palace of Woodstock was pulled down, regardless of its antiquarian interest, in 1711, when a new edifice arose, in another part of the park, destined for the residence of the great and successful soldier.

On entering the domain, the spectator is at once struck by the breadth and grandeur of the laying out of the park, which was the work of the often-decried Brown, one of the earliest of our professional landscape planters. He is distinguished from other Browns as "capability" Brown, from his being quick at seeing, and speaking of, the "capabilities" of a place which he was called upon to improve, or of a site upon which he was employed to create a landscape. He most certainly did perceive the capabilities of the ancient domain of Woodstock, which he improved into the park of Blenheim with masterly grandeur of effect; and it must be admitted that many of his successors, though his severest critics, were also his imitators. On approaching the palace, a small portion of the great lake is perceived, lying amid slopes dotted with noble detached trees, backed by great undulating woods, the water view being terminated by a highly decorative bridge of very grand effect, notwithstanding its rich detail. Advancing towards the main façade of the palace, the extensive left flank of the building is first seen, the long architectural lines being gracefully interrupted by the spreading branches of one or two nobly grown trees. Further on, the view over the park becomes more extensive, some grand old centenarian Cedars contrasting strikingly with the lighter foliage of the deciduous trees on the far-reaching green slopes, with great pictorial effect.

When the principal front of the palace is reached, the effect of the architecture is exceedingly impressive; there is a general broadness of treatment about it; a skilful management of those bold projections, which afford variety of light and shade; and there is also such excellent design in what architects call the sky-line, as at once proclaims the structure one of the architectural masterpieces of the reign of "Good Queen Anne." Turning round, and looking in the opposite direction, is seen the spacious approach to the bridge over the narrow part of the lake; and, on the rising ground beyond, which attains a considerable elevation, rises the column surmounted by the statue of the first duke. From this spot, in fact, a semi-panoramic view is spread out before the spectator, from which glimpses of the larger lake are obtained between the trunks of finely-grown trees, while beyond, on all sides, are gracefully undulating slopes, and noble detached trees, and massive and far-extending woods, such as are rarely surpassed even in the most perfect examples of our English park scenery.

Before penetrating the more distant recesses of the woods, and avenues, and wildernesses of Blenheim Park, I resolved to enter the house—or rather palace, as it is called—and ascertain whether the views from the principal windows had been as duly considered as the views from the approaches—whether architect and landscape-maker had acted, in respect of window views, with persistent independence of each other, or had worked well and thoughtfully together. In creating a new place, the planting, close about the mansion, so as to soften and vary the architectural effects; and the arrangement of the principal windows, so that they may command the finest and most appropriate outlooks, I look upon to be among the most important points to study; and one in which the architect and the horticulturist should always work together. On entering the inner hall, neither the painted dome, nor rich architectural accessories, nor the exquisite portrait of the third Duchess, by Romney, were what I desired to examine; and, in spite of my attention being earnestly called to them by the "groom of the

VIEW IN THE GROUNDS AT BLENHEIM.

chambers," I hastened at once to the principal window, and was not disappointed with the view. There were the tower of Blaydon Church, nestling picturesquely among the ancient woods, and, nearer, some grand sweeps of turf, enriched with finely-grown trees, especially two Cedars of Lebanon. From the windows of the three drawing-rooms the views are quiet and pleasing: there are grand distant woods, with green slopes, and fine trees in front, including a grove of several Cedars. As "the groom of the chambers" would not move forward till he had most fully described the tapestries which decorate these three rooms, I was compelled to hear his account of them, even to "the bitter end." They are, in fact, very well-woven tapestries, as tapestries; but, as to being accurate representations of the respective battles which are supposed to be thereon depicted, they are truly ridiculous performances. There is no attempt whatever to show, however vaguely, the disposition of an army, or the nature of the respective sites. One after another these compositions consist of a mechanically fine cluster of trees, beneath which a group, or two groups, or three groups of noble cavaliers are seen capering about, in the full-blown military costume of the period, on prancing steeds—white, grey, chestnut, black, and brown. Among these dashing gentlemen, "le bel Anglais"—the gallant Churehill himself—is always the most conspicuous figure; while a little smoke in the background represents the contending armies. Thus the composition, called the "Battle of Malplaquet," would serve equally well for that of Oudenarde; and Oudenarde would, on the same principle of battle-painting, be as perfectly satisfactory if called the battle of Blenheim.

At last we passed on to the library, and "the groom of the chambers" having no remarks to make upon the books, I had all the time to my windows and my views. From the first window I was much pleased by a group of Cedars, and some well-selected Thujas on a steep slope, casting their shadows of strongly-contrasted forms over some of the most velvety and beautifully shaven turf I have ever seen. A similar view, equally pleasing, but less striking, was commanded by the second window. The left division of the great bow commanded a venerable old Cedar, rigid and angular in its aged and hoary magnificence; and below it was a lovely slope, planted with young Coniferae of various kinds. From the right division of the bow the spectator looks over a geometrical flower garden, of poorish design, but forming a pleasing variety to the surrounding irregularity. Beyond are deciduous trees, whose foliage of every shade of vivid green mingles pleasingly with the more uniformly dark hues of Pines and other Conifers—between the trunks of which gleam, like lights, narrow and fitful glimpses of the upper lake. This portion of the view from the right hand section of the great bow forms a truly noble home landscape. A door on the opposite side of the library opens to a fine colonnade, commanding a view over the principal lakes and woods, which display from that point the grandeur and yet simplicity of their design with great effect. From the windows of the suite of rooms containing the pictures, many of them undoubted works of the "great masters," and several of them masterpieces, the outlooks are always pleasing, though seldom striking; but the end windows of the last room, which command another aspect, reveal to the spectator many pleasant features of a true home landscape. In the foreground is a very gracefully designed geometric flower garden, the intricate interweaving of the lines of which is worthy of the delicate pencil of a mediæval illuminator—and beyond is a noble avenue, the soft shades of which terminate against a background of massive tufted woods; the avenue itself being flanked by detached Cedars, ancient Elms, and other trees.

It was now high time to take a rapid survey of the park, but just as I was hurrying through the great gateway, a storm of thunder and lightning, accompanied by torrents of rain, suddenly burst forth; however, having gone down from London expressly to stroll through Blenheim Park, and study the horticultural devices by which the celebrated scenery had been produced, I felt that thunder and lightning, with an hour of drenching rain, ought not to prevent me carrying out my project; and it didn't. I borrowed an umbrella of the porter and sallied forth. My first object was to find out whether any portion of the old Royal Park of Woodstock, or any of its ancient trees remained; so following the direction indicated

to me as that leading to the spot where the old palace once stood, I thought that situation the most likely one in the neighbourhood of which to find relics of the past. I think I was not mistaken. After diverging from a short double row of Elms, to which I was tempted by a glimpse of what I thought was the ruin of an aged Oak, I arrived at last in a portion of the park which I fancy (only fancy) may have existed in the times of Eleanor and Rosamond. The long rich Grass is studded with noble centenarian Oaks, and also by others, with vast hollow trunks, bark-stripped and grey with hoary age, the ancestors of the youthful centenarians. These venerable tree ruins, outstretching their gaunt, bare arms, seem to be trying to reach back towards the times of their youth. Some of them have still a green spray here and there on trunk or limb, like the sparse hairs of a very aged man; but as a rule their naked trunks and great gnarled limbs are bare, gray spectres of their former stately being. I fancied that Rosamond and her royal lover might have wandered beneath their shade, furtively watched by the jealous Eleanor in the summer evenings of that far-off time. I wonder that artists have never found out this spot and peopled it on canvas in some such fashion as that I have suggested.

Returning by another path I took a fresh start from the front of the principal façade, and hastened on to the bridge to study the formation and planning of the great upper lake. I once had an impression, the result of a visit many years ago, that its extent was not so skilfully concealed as it might have been; but my present view of the results obtained by the original planning quite removed that hasty and erroneous impression. By means of planted banks, jutting far out into the water, and other well known, but seldom skilfully applied devices, the extent appeared immense, and no termination of the vast silvery sheet was visible. It is certainly a grand and successful example of artificial lake-making, to which the trees, with the venerable grandeur they have now attained, impart the fullest effect, and their quaint irregularities give such bold touches of pure nature as totally conceal all traces of artificial creation. Crossing the bridge, and descending a path crisp with cones and Beech husks, I found myself at Rosamond's Well, now a small square pond palisaded round—but once, no doubt, a small spring, or well, as springs were formerly called,—such as holy well, or healing well, or Our Lady's well,—quite a different thing from the deep artificial sinkings which we now call a well; while we should call Rosamond's well a "spring." Above the "well" the rising ground is studded with some of the finest and oldest Cedars in the park, from between and about which, looking over the lake, a magnificently picturesque view of the palace is obtained. Above this lies some wild ground, Fern-clothed and rugged, and shaded by deciduous trees of various kinds and ages, which appears to be a favourite haunt of the deer. There is a distant view of the palace obtained from this spot, which, seen by moonlight, and with the nightingale's song to furnish woodland music, must be very charming. It is this view, by moonlight, which is represented in our annexed illustration of Blenheim Palace and Park.

NOEL HUMPHREYS.

## THE DODDERS.

BY W. CARRUTHERS, F.R.S.

THE Dodders form a group of plants which are very closely related to the Bind-weeds (Convolvulaceæ), yet are separated from them by many important characters. Some fifty species are recorded from all parts of the globe, and though they can be specifically distinguished, no peculiarities exist among them of sufficient importance to justify the establishment of generic groups. All are included in the one genus *Cuscuta* established by Linnæus. They are all annual parasitic herbs, with thread-like stems, entirely leafless, or having the leaves represented by a few scattered minute scales. The small reddish flowers are united into little round balls. Each flower produces four small seeds about the size of a grain of mustard. The mass of the seed consists of a fleshy albumen in which is spirally coiled a thread-shaped embryo. Gaertner first showed that, while these plants agreed in every way with other dicotyledons, they differed in the fundamental character expressed in the name, in having, as is supposed, only a single cotyledon in the embryo plant, but in reality this supposed cotyledon is only the axis or stem of the plant, without any leaf appendages whatever. As all the Dodders are annual, and they have no roots protected in the ground, the

winter completely kills all the plants of each season's growth. The ripe seeds, however, supply the means in them, as in other annuals, of reproducing with the new season the destroyed plants of the last—for each perfect seed contains a minute bud, capable, though separated from the parent plant, of maintaining a dormant existence, and, under suitable conditions, of starting into independent active life. Each seed encloses, either in the tissues of the embryo plant or surrounding it, a quantity of food sufficient to support the young plant until its organs are developed so far as to obtain its own food.

In *Cuscuta*, the albumen in which the embryo is enclosed supplies it with food enough to enable it to lay hold of the stem or branch from which it will draw its nourishment, if that is within reach. It is unable to maintain its life after the stock of food laid up by the parent is exhausted, so that it dies if it does not succeed in attaching itself to a living plant. Mr. Buckman has shown that, when sown with seeds of suitable plants, the ordinary internodal lengthening of the supporting stem lifts with it the young parasite from the earth. When, on the other hand, it attaches itself to grown plants, all connection with the earth is speedily cut off, and the lower extremity of the filiform stem is left suspended from the nourishing plant.

When the Dodder touches the supporting plant, it twines round the stem, and from the inner surface of the coil throws out a series of suckers, by which it secures a living connection with the stem. Through these suckers it withdraws the elaborated juices from the plant for its own use, and, from its rapid growth, it soon impoverishes, and ultimately kills, the supporting plant. It has already, however, thrown out branches by which it has seized hold of new

Trefoil Dodder (*Cuscuta Epithymum*, var. *Trifolii*).

plants, and it continues to extend its relations as long as the season permits the parasite itself to live. In this way a single plant, by its rapid growth, will cover in time several square feet of ground, and impoverish, or completely destroy, a great number of plants belonging to different natural orders. The most common British species, *Cuscuta Epithymum*, Murray (of which the Trefoil Dodder, *C. Trifolii*, Bah., is only a variety), was first noticed, as its name almost implies, growing on Thyme, but it is found on other and very different plants, as on Furze, Broom, Trefoil, Lucerne, Rock-rose, Cranberry, Heather, Centaury, Scabious, Grass, and even on the Brake. It is also found living on plants that are themselves partial parasites, like Eye-bright, Yellow-rattle, and bastard Toad-flax.

The structure of the Didders, and the nature of the relation between them and the plants on which they are parasite, have been investigated by Mibel, Unger, and especially by Chatin. Being complete parasites they are without the food-producing or food-procuring parts of ordinary plants, viz., roots and leaves. Nor have they any of the green colouring matter (chlorophyll) which plays an important part, in elaborating the food of vegetables, yet not an essential part, as is shown by the experiments of Saussure and De Candolle on *Atriplex hortensis rubra*, and *Ulva parparea*. The minute scales and flower bracts, which are the only representatives of the leaves, are, as well as the stem, completely destitute of stomates. The stem consists of a cellular pith surrounded by a woody

structure, which differs, however, from the wood bundles of other dicotyledonous plants in being destitute of ducts, of medullary rays, and of liber. There is, consequently, no true bark; its place is occupied by a cellular layer surrounding the wood cylinder, the cells of which contain a red liquid, and are more or less charged with starch granules. The suckers are developed from the stem. The flattened portion is derived from the external layer of cells. Through this is pushed a cone composed of the cellular pith and woody structures of the axis. These penetrate the stem of the supporting plant. It is not easy to understand how these delicate cell structures penetrate the firm fibro-vascular tissues while they are in active life. The same problem presents itself in investigating the growth of all the phanogamous parasitic plants—of the Mistletoe on the Oak or Apple, as well as the Dodder on Clover.

In penetrating the stem the tissues of the attacked plant are not injured; they are only pushed aside by the advancing cone, and the cells of the parasite are placed in such close relationship to those of the supporting plant that the organised juices pass freely from one to the other, entering the Dodder just as they would pass into a branch of the plant itself. The relation of parasitic fungi to the plants on which they grow is very different from what occurs in the Didders and the other higher parasites. The small roots, or mycelium of the fungi, penetrate the walls of the cells, and live upon the tissues themselves, or on the starch or other contents of the cells. The result is, consequently, the disorganisation and destruction of the plants attacked by the fungus. The higher parasites, on the other hand, only withdraw the organised juices. This operation is without any real injury to the supporting plant, if the proportion of the juice withdrawn by the parasite is small in relation to what exists in the whole plant, as is generally the case with the Mistletoe on the Apple: or it is fatal to the supporting plant, as in the case of the Dodder on Trefoil, where the rapid growth of a large parasite withdraws all the prepared food, and kills the plant by exhaustion. The enormous mass of the Dodder also destroys the Clover which it covers, by smothering it in the same way that any other heavy and dense covering would. Of the many remarkable problems suggested by the study of the Didders none is more strange than the physiological inquiry as to how, without any appliances for obtaining food from the air or the soil, and entirely dependent on the prepared juices of the plants on which they live, they nevertheless contain in their tissues starch, resin, and different acid substances which are not found in the nourishing plants, and, on the other hand, they want some of the chemical elements which abound in these plants. And, still further, how a single plant of Dodder collecting its food from plants so different as Clover, Heather, Thyme, and Grass can convert the diverse juices of these various plants into products which are completely unlike any found in each or all of them.

Considerable alarm has at times prevailed in various districts when the Clover or Flax has been extensively preyed upon by this dangerous parasite. The appearance was of course due to the use of seed (generally foreign) containing Dodder. There is really no excuse for seedsmen permitting Dodder to accompany Clover seed, inasmuch as the small size of the Dodder seed (being only half the size of Clover) permits it to be easily separated by the mechanical process of sifting. When, however, the cultivator has the misfortune to discover Dodder on his farm, he should use the utmost diligence to secure its destruction. No attempt at tearing the Dodder to pieces will destroy it; indeed, each separate piece that remains connected with the living plant will maintain its independent existence. Permitting the Dodder to die on the field is also utterly worthless for the purpose of securing its extirpation, for the seeds remain, and when the spring returns they will germinate. The only efficient cure is to burn completely the whole vegetation of the diseased spot, together with the surface of the soil on which the seeds may already have fallen.

Flax and Clover crops are not the only ones that may be injured by Dodder. The Thyme-Dodder, of which the Clover-Dodder is, as I have said, but a variety, has been found on plants belonging to the same genus with the Potato; and my attention was drawn last autumn, by Mr. Braudreth Gibbs, to crops of Swedish Turnips attacked by this plague. The field was near Dunstable, on the Braudreth estate. The farmer, Mr. Scroggs, informed me that, two years before, the field had produced a good crop of Trefoil, which was here and there affected by Dodder. Mr. Scroggs cut down the Clover, leaving the diseased plants to die on the ground, and then ploughed them into the soil. No indication of the parasite was detected in the Wheat crop which followed the Clover, but the plough having brought the seed again to the surface, it germinated after lying a year dormant, and attacked the crop of Turnips then growing on the field. The suckers of the Dodder had penetrated principally the fleshy stalk and midrib of the leaves, but not a few of the Turnips themselves were also attacked on the upper surface.

## THE FRUIT GARDEN.

### VINES IN ROCK BORDERS.

VINES seem to acquire wonderful luxuriance in the native rock which we have hereabouts. I was induced last July twelve-months to break up 18 inches of rock in front of our Vine pit, breaking it to about the size of road metal. I then planted some young Vines, about the size of Wheat straws, in this rock, with just a little soil to keep it together, and was fortunate enough to ripen a few eyes inside the pit. I allowed one on each Vine to break, and succeeded in obtaining 30 feet of good strong wood last summer, which is only intended to bear a bunch or two, to prove some of our new Vines. Such seems to be the value of this rock that I think of taking out one light width of our present Vine border and substituting some of the rock, for I am of opinion that we have a mine of Vine border materials which only want to be dug up and planted to supersede all our chopping and mixing by weight and measure. The growth this season is very favourable. Five of the young Vines are bearing fruit, a few bunches of which have been left, just to prove the kinds. The Royal Ascot and Golden Champion are colouring and very healthy, the others are later, and I have no doubt will prove satisfactory. As has been already stated, they had at first only 18 inches wide of the rock broken up for them to grow in, but in order to give them a good start I broke up 3 feet more in width and 18 inches deep of the rock, and, in so doing, found it occupied with very fine thread-like roots, although so solid as to be only capable of being broken up with a pickaxe. This unexpected disturbance of course gave the plants a slight check, but I believe they are all right again. The original Vine, already alluded to, is still doing well; it consists of one shoot 120 feet long, and contains 132 bunches in various stages of growth, from some just ripe and perfectly black, to others not long thinned out. The Vine has never had any soil or manure given it since it was planted; it is a truly wonderful Vine. I ought to say that I have removed part of a Vine border, taken up one Vine, lifted the roots of another, and replaced the border with broken rock. In this I intend to plant young Vines. The lifted roots were laid in the new-made rock border, and have suffered no check. The Vines, in fact, are bearing a good crop of late Grapes.

F. JOYNS.

### MUSCAT OF ALEXANDRIA VINES.

SEVEN years ago I planted strong canes of this Muscat, and during the first year they were not allowed to bear. The second year a few bunches were taken off them, and the third and fourth years they were heavily cropped, each Vine carrying about twenty-four bunches; the fifth year they showed fewer bunches, the sixth year fewer still, and the present year about the same. They are grown on the long rod system, and the wood breaks more weakly each year; the foliage is healthy, but late in falling off. The border is wholly inside, walled all round, and when made the original soil was removed to the depth of 2 feet 6 inches, to a bed of clay of great depth; upon the clay was placed 6 inches of cinders and 2 feet of rich compost, such as is usually employed for Vines; each Vine was allowed 6 feet by 5 feet of border; two years since the inside wall was removed, and 2 feet added to the border; it was then found that the roots had gone down the side of the wall into the clay, that they were the thickness of the thumb, and were traced to the depth of 3 feet in the clay, scarcely any fibres being found on them, and on the new piece of border being examined this spring, it was found that there were no new roots in it. I am, therefore, of opinion, 1st. That no border, and especially if limited to a small space and on clay, ought to be made without a paved bottom, through which no Vine root can get. 2nd. As the Vines are expected to improve for the next twenty or thirty years, they ought to have been allowed at least ten times the size of border which was given them. 3rd. I propose to take up the Vines at the proper season, carefully preserve the fibres, cut off all tap roots, and replant them in an enlarged border properly made.

T. D.

[Your Muscat of Alexandria Vines appear to have been judiciously cropped for their age, and their failure after the fifth and sixth years' growth is no doubt partly owing to the confined inside border and the roots getting into the clay subsoil. The remedy proposed is in my opinion the best to try under the circumstances, namely, to take up the Vines at the proper season, carefully preserving all the roots with fibres, and to replant them in an enlarged border properly

made. In 1864 I replanted seventeen Muscat Vines, twelve years old, in a large Vinery in the new gardens here. The situation was damp, with a strong red clay subsoil; but it was firmly concreted, and air drains were made with 4-inch tiles, laid every 4 feet across the border on the top of the concrete. All the spaces between them were filled up with broken bricks, clinkers, and lime rubbish, so as to cover the tops of the tiles. These Vines bore a full crop the second year after they were replanted, and have borne large crops ever since. I should advise your correspondent to replant his Vines inside the house; but when he enlarges the border, to make the largest portion of it in the outside, so as to give the roots full liberty to run out. The newly-replanted Vines will be much benefited by having their roots covered on the outside border with some fermenting materials before they begin to break in the spring.

—WILLIAM TILLERY, *Wfelbeck.*]

**Beurre Dubuisson Pear.**—Respecting this Pear, which attracted so much attention last season in Belgium, we read the following remarks in the *Bulletin d'Arboriculture*:—"We consider the Beurré Dubuisson the most valuable acquisition of the present generation, as it equals the finest October Pears in quality, and is in perfect condition in February and March—a time when thoroughly melting fruits are not to be had. It has, moreover, another invaluable quality, viz., that of keeping ripe in a fruit-room, without suffering any change, for four months, commencing from the beginning of December." The following description of this Pear is given by M. Du Mortier, in the *Pomone Tournaisienne*:—"Fruit very large, oblong, slightly indented, truncate, and ribbed at the base, somewhat attenuated towards the top. Stalk short, thick, oblique, not much sunk in the flesh. Skin yellow, dotted and spotted with russet, sometimes slightly coloured on the side next the sun. Flesh fine-grained, buttery, sweet, slightly aromatic, and very juicy. Quality unsurpassed." The Beurré Dubuisson is finely figured in the *Bulletin d'Arboriculture* for September 1872, where its aspect in the coloured plate fully supports all that has been written in its favour.

**A New Late Peach.**—Under the name of Pêche Belle de Saint-Geslin, a new Peach is described, in the last number of the *Revue Horticole*, as the latest-ripening kind known to French cultivators. The stock from which it sprung was discovered some years since growing amongst the ruins of the old tower of St. Geslin, near Richelieu (Indre-et-Loire). The discoverer (M. Jontrom) finding that it fruited much later than any of the other kinds he possessed, continued to propagate it. The quality of the fruit is excellent, the flesh being very melting and sweet, with a slightly perfumed flavour. It is also of large size and handsome appearance. Its chief merit, however, is that it ripens as late as the beginning of November, somewhat later than the Salway Peach. The tree is described as a vigorous grower, with long stout branches covered with bark of a uniform blood-red colour. Leaves long, oval-lance shaped, very finely toothed. Flowers like those of Grosse Mignonne.

**The Training of Fruit Trees.**—The following, which we extract from a foreign journal, though not new, may prove a useful hint to beginners engaged in training fruit trees:—"In 1870 M. Chevalier, of Montreuil, planted a young tree of the Grosse Mignonne Hâtive Peach, which he destined for training in the U form. For this purpose two nearly opposite buds were allowed to remain near the base of the stem, in order to form the two main branches of the U. One of these buds, during the first year, produced a shoot more than 3 feet long; while the opposite bud made only a very short and feeble shoot. With the view of equalising the growth of the two shoots, M. Chevalier cut off the half of each of the leaves on the stronger shoot, leaving those on the weaker one untouched. The result was that the vigour of the stronger shoot was so checked, while the other continued to push, that the growth and size of both are now perfectly equalised and symmetrical." It is necessary to add that this cutting of the leaves must be performed carefully and by degrees, otherwise the shoot so operated upon may be very seriously injured.

### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Mulching Strawberries.**—Strawberries and black and red Currants appear to be bearing exceptionally fine crops this season. I hear from Kent, that they are literally loaded with fruit. Strawberries, if not already done, should be mulched at once; mulching has the double advantage of keeping the fruit clean and the roots moist and cool.—R. GILBERT, *Brightly.*

**Potash for Peach Trees.**—At the meeting of the Cincinnati Horticultural Society, the President alluded to potash as a most excellent fertiliser for Peach trees. He had a Peach orchard of about twenty-five acres; the soil was poor, and manured with potash only. He dissolved it in water so that the lye would be so weak that a Potato put in it would not quite come to the surface, and then applied two quarts of this liquid close around each trunk every spring. His crop had been in 1867, 1,500 bushels; in 1868, 600 bushels; in 1869, 1,400 bushels; in 1870, 350 bushels; and last year, 1,800 bushels.—*Cincinnati Farmer.*

## THE GARDEN IN THE HOUSE.

### ARALIA VEITCHII.

As a plant for dinner-table decoration, this lovely *Aralia* is hardly surpassed, even by the finest and most graceful of Palms. It is a slender-growing plant, producing an abundance of handsome digitate leaves, having from nine to twelve filiform leaflets, the edges of which are beautifully undulated. The leaves are of a dark metallic-green colour above, and of a dark reddish hue underneath. This fine species was intro-

### A BOUQUET OF FLOWERS FROM CAPE BULBS.

I HAVE lying on my table just now some floral gems culled from Cape bulbous plants, and in passing them through my hands I have thought that some of your readers might like to know something about them. The first that comes to hand is *Babiana grandis*, the colour of which is a rich crimson magenta, suffused with lake; in the sun the glow is intense. Next comes *Tritonia Brilliant*, the beautiful luminous orange-scarlet flowers of which are exceedingly effective in vases. Then follows *Antholyza fulgens*, the beautiful rich scarlet

*Aralia Veitchii.*

duced into this country from New Caledonia, a few years ago, by Messrs. Veitch and Sons, of Chelsea. It has received the highest awards that could be given to a new plant, both in this country and also on the Continent. It thrives best in a moist-stove temperature; but, in summer, it does well in an intermediate house. It should be grown in a compost of peat and loam in about equal proportions, with the addition of some silver sand. Young plants of it are best for house decoration, as this *Aralia* is not a very rapid grower there is little fear of its getting too large for that purpose; and as it preserves its leaves for a long time, there is not much danger of its becoming naked stemmed.

towering spike of which is set in the centre of the bouquet. I will now take the exceptional coloured flowers of *Ixia viridiflora*, the sea-green of which sets off the crimson centre to advantage. Surrounding the whole, I have placed *Ixia Lady Slade*, the loveliest of the roses; *Crateroides*, the sweetest of the cherises; *Bucephalus*, representing magenta; and *Vulcan* at the head of the crimson. Of the yellows, *Merveilleuse* is the largest, the lightest, and the most beautiful; *Titus* the darkest and the smallest. Then of yellows which, when closed, show the crimson most, I would name *Plautus*, *Constance*, *Conqueror*, and *Golden Drop*. Those with the crimson least conspicuous consist of *Aurantia major*, *Triumph*, and

La Majestneuse. Amongst whites and primroses, there are Virgilius, a gem, almost pure white with a crimson centre; Scilla, white, with a black centre, the outside petals being lined with crimson; Pallas, very much in the same way; Gem and Luna, differing but slightly from those just named; Aspasius, still white, with a dark centre, but when closed shaded with red; Model, fawn-coloured, with dark centre and outside petals tinged with rose; Giant and Clarus, very much alike, red and white when open, parti-coloured when closed. My bouquet contains many other varieties, but I have given you the names of my leading kinds: and now a word about their culture. A piece of ground lying well to the sun, protected, for instance, by a wall, greenhouse, or other structure, is the best position for Ixias, Sparaxis, Tritonias, Babianas, and similar Cape bulbs. The ground should be well drained, the compost at least two-thirds good loam, and the roots planted from 4 to 6 inches deep. During severe weather, hoop the beds over, and protect them with mats, or, in the absence of mats, with litter. The chief danger lies in the plants starting early into growth, and when that is the case, care should be taken to keep the foliage free from injury. If treated as has just been directed, abundance of these beautiful flowers may be cut during the latter part of May and the month of June for furnishing vases, if required; and if not, no group of plants will furnish the cultivator with more interest and variety. As pot plants they are most charming, and easily managed. I have grown them in a great variety of ways, and planted them at various times. This season my largest planting was in January, and I observe that the Sparaxis are just coming into flower. I am, therefore, looking forward shortly to a grand display.

IRID.

**Watering Window Plants.**—"Water," it is generally said, "should be given in moderately small quantities, and supplied frequently." Few people, however, who have had any experience, would sanction such a system, knowing too well what would be the consequences; and I believe if the causes of failure in so many instances, where plants are cultivated in windows, were minutely investigated, the dribbling system of watering would be found to be the principal cause. I am fully convinced that a plant ought not to be watered until it is in a fit condition to receive a liberal supply of that element, having previously secured a good drainage in order that all superabundant water may be quickly carried off. I do confidently assert that those who are constantly dribbling a moderately small quantity of water upon their plants will not have them in a flourishing condition for any length of time. This must be obvious to all, for it is quite evident that the moderately small quantity of water frequently given would keep the surface of the soil moist, while at the same time, from the effects of good drainage, which is essential to the well-being of all plants in an artificial state, all the lower roots would perish for want of water, and the result would be, that the plant would, sooner or later, become sickly, and eventually die.—A. B.

**A Greenhouse of Artificial Flowers.**—Forty-one of the leading artificial flower-makers of Paris have combined to send to the Vienna Exhibition a specimen of their united skill, which will prove incontrovertibly that the capital of France still reigns supreme in the matter of artificial flower manufacture. This patriotic contribution consists of a complete greenhouse, filled with flowers of every description, perfectly imitated. In it are Hyacinths, the illusion of which are the fibres thrown out by the roots; bouquets, in which one sees the flower freshly-blown, and that which has been in existence but two hours; wild flowers, the soft gray down of which seems ready to float away. The whole work is a marvel of artistic skill and unexampled patience.

## NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

**Viburnum plicatum.**—This hardy flowering plant does well in a window balcony, in which it produces its white balls of flowers in abundance. I find good turfy loam and thoroughly decayed manure or leaf-soil to be a good compost for it. If in a plant case, it should have plenty of water and a position near the glass when it begins to grow.—Geo. DOUGLAS.

**Mother of Thousands.**—I noticed that this common window plant held a prominent, and even effective, place in the table decorations exhibited last month at Alexandra Palace. In the topmost tier of one of the March stands were inserted, amongst flowers and Fern fronds, one or two pieces of this Saxifrage, in such a manner as to permit the runners bearing their tiny off-spring to hang down gracefully over the edge, thus giving the vase a well-furnished, yet light and elegant, appearance.—EDITH SOMERVILLE.

## THE HOUSEHOLD.

### SORREL.

This vegetable, if not nutritious, is wholesome, and, when properly treated, particularly nice. The peculiar acid taste of Sorrel is very agreeable, and in my opinion comes next after the exquisite sub-acid flavour of not over-ripe Tomatoes. Sorrel, however, in this country, is as little known as Laver out of Ireland or Cornwall; and, although it grows wild in our lanes, it is not easily obtainable at ordinary greengrocers. Then there is the stubborn prejudice of all true Britons in matters of food, which makes them look upon all things acid, other than the contents of the pickle jar, as highly unwholesome. I have my doubts whether the same individual who will contentedly feed off mackerel or salmon soured in wood vinegar could ever be induced to eat a plateful of *soupe à l'oseille*. There are a number of soups in the composition of which Sorrel enters in greater or lesser quantity, and these I will first describe, promising that, to whatever use Sorrel is destined, it cannot be too carefully picked and washed clean. In some instances the stalks must be rejected, and the leafy part of each leaf alone used. The following are various forms of the homely *soupe à l'oseille*:—

1. Take a pound of Sorrel, pick the stalk from each leaf, shred the leaves coarsely, and put them into a saucepan with an ounce of butter, keep stirring for some minutes; then add about a quart of stock, free from fat, and let the whole simmer till the Sorrel is done; add pepper and salt if necessary; then beat up the yolks of two eggs with a little of the stock, and stir them (off the fire) into the soup, which is then poured over small slices of stale bread and served.

2. Treat the Sorrel as above, and with the stock add two or three Potatoes cut in small dice; finish as in the preceding recipe, and serve with or without the bread.

Both the above formulas can be carried out *au maigre* by using water instead of stock; and a more elaborate kind of *soupe à l'oseille*, either *au maigre* or *au gras*, can be produced as follows:—Wash, pick, and shred a pound of Sorrel, put it into a saucepan with a head of Lettuce shred finely, a handful of Chervil, and 2 ozs. of butter; stir on the fire for about ten minutes, then add a quart of stock (or water), pepper and salt to taste, and a dust of powdered nutmeg; let the whole simmer half an hour, then stir in, off the fire, the yolks of two eggs beaten up with a gill of cream. Pour the soup over some diminutive slices of stale bread (neither toasted nor fried), and add a piece of butter as big as a Walnut. This nearly approaches the well-known *Bonne femme* soup, which can be made thus:—Cut up a good-sized Onion into very thin slices, place these in a saucepan with a good allowance of butter. Take care not to let the Onion get brown, and when it is half done throw in two or three handfuls of Sorrel, a Lettuce, and a small quantity of Chervil, all finely cut; add pepper, salt, a little nutmeg, and keep stirring until the vegetables are nearly done. Then add a tablespoonful of pounded loaf sugar and half a cupful of stock or broth, free from fat, and not coloured. Let the mixture reduce nearly to a glaze, pour in about a quart of stock or broth as above, and, after the soup has given a boil, it can be put aside until the time of serving. Meanwhile prepare about a dozen and a half very thin slices of bread, about 1 inch wide and 2 inches long, taking care that they have crust along one of their long sides, and dry these thoroughly in the oven. When it is time to send up the soup, first remove the superfluous fat from it, then set it to boil, and, when it boils, stir into it (off the fire) the yolks of two or three eggs beaten up with a gill of cream or milk. Pour the soup over the slices of bread, and serve when the bread has had time to soak. Sorrel shredded more or less coarsely is an agreeable addition to every variety of spring soup, *au gras*, in clear *consommé*, or *au maigre*, with a *liaison* of yolks of eggs and cream. It can also be used in conjunction with farinaceous substances, as in the following two soups.

1. Boil some rice in water; when half done drain off all the water, and finish cooking the rice in some clear stock. Then add, according to taste, more or less Sorrel, finely shred, boiled in salted water till done, and strained.

2. Make a very thin porridge by strewing a small quantity of semolina in some well flavoured stock, and stirring on the fire till it is well done; then add Sorrel prepared as in the foregoing recipe.

In both recipes salt should be added if necessary, and the stock used should be free from fat and well flavoured, by which I do not mean strongly, but judiciously flavoured—according to art. Another variety of Sorrel soup is that of *purée*, the common form of which is as follows: Boil the Sorrel in salted water; when thoroughly done, drain all the water off, and pass the Sorrel through a hair sieve; and I may mention, in passing, that the majority of cooks have a strong objection to using hair sieves for passing Sorrel, Spinach, and vegetables generally, on the plea that it is harder work and takes a longer time

than when a wire sieve is used. Wire sieves are made of copper or of tinned wire. The use of the former I strongly deprecate, not only for substances containing acids apt to act on the copper, but for any purpose whatever, for it is next to impossible to prevent some oxidation taking place; and, although the quantity of verdigris which may thus be introduced into food may not be sufficient to kill or even to cause any disturbance in the system, yet food is the best with no traces of oxide of copper in it. The tinned wire sieves are unquestionably preferable, and if some rust does find its way into the food it is rather beneficial than otherwise. Still for Sorrel, or any substance containing strong acids, I prefer a hair sieve; and I may add that there are hair sieves to be had quite as coarse as any wire sieves. But returning to the *purée* of Sorrel, the next step is to melt a piece of butter in a saucepan, amalgamate with it a table-spoonful of flour, and when the flour is cooked to stir in the Sorrel pulp; then add a sufficient quantity of plain stock to make the soup of the desired consistency, season with pepper and salt, and pour it over small dice of bread fried in butter. The above formula may be varied in many ways—by the addition of a little sugar, a small quantity of grated nutmeg, by stirring into the *purée*, off the fire, *liaison* of yolks of eggs beaten with a small quantity of cream or not as the case may be. Plainly boiled rice may be served in the *purée* instead of fried bread. Then again the *purée* may be compounded in the manner following: Fry a sliced onion in butter, add some flour, then the Sorrel boiled, strained and chopped, pepper, salt, a little nutmeg, a little sugar, and a small quantity of stock; stir the whole well on the fire, then pass through a hair sieve; dilute the result with more stock, and finish with a *liaison* as before, serving over fried dice of bread. Other vegetables, such as Spinach, Lettuce, Chervil, and Parsley, can be used in combination with Sorrel to compound the above *purée*. When the *purée* is intended to be used as a "vegetable" or as a garnish to an *entrée*, the process is exactly the same, with the single exception that less stock and more flour are used, so as to give the preparation a greater consistency. If intended to garnish a fricandeau, some of

ROYAL HORTICULTURAL SOCIETY'S SHOW AT BATH.

The ground on which this exhibition is to be held is situated in the Royal Victoria Park, Bath, in the midst of one of the most favoured spots for picturesque beauty in the West of England; it occupies an area of about 13 acres, and is on the western side of the city, about a quarter of a mile from the new station of the Midland Railway Company, and three quarters of a mile from that of the Great Western. It is the intention of both these companies to run excursion trains from the principal towns on their lines of route during the show. What is called the Model Garden, of which we give a plan and

sections, has been tastefully laid out by Mr. Eyles, and will, when furnished with plants, have a fine effect. The society may, indeed, look forward with every confidence that the show which is to open on Tuesday next will be one of the most attractive and successful of its meetings yet held in the provinces.

The chief display of Palms, Tree Ferns, and the more important stove and greenhouse plants, will be arranged in a tent 260 feet long by 120 feet wide, and will present the appearance of a tropical garden.

Large tents will also be filled with other varieties of plants, fruits, cut flowers and vegetables, and some will be appropriated to the display of table decorations, and specimens exhibited by cottagers and artisans, and the exhibition of articles in the industrial department will, we understand, be on a very extensive scale—and will include, besides horticultural buildings, wirework, rustic arbours, and bridges, heating apparatus, &c. In the principal tent a quantity of perforated stones obtained from Claverton Down has been artistically grouped, so as to form a grotto and cascade. This ornamental erection has been tastefully decorated with Ferns. The park itself is well laid out, varied in surface, and contains

Plan of the show ground of the Royal Horticultural Society at Bath.

the liquor in which the veal has been braised should be used instead of stock to moisten the *purée*. Veal cutlets, pork chops, escalopes of rabbit, and every form of white meat can be served with a *purée* of Sorrel. Boiled fillets of sole may be in worse company than with such a *purée*; and poached or fried eggs go very well with it also. A well-made plain omelet laid on a bed of Sorrel is an *extremet* not to be despised; and lastly, the *purée* may be garnished with "quarters" of hard boiled eggs and triangular sippets of bread fried in butter. The young leaves of Sorrel dipped in butter two at a time and fried are one of the numerous varieties of the genus fritter. To make this particular kind, however, the operator must be well skilled in the art of frying; for in cookery—as, indeed, in everything else—I need not say the simpler the operation the more difficult it is to carry it out creditably. —Queen.

an excellent selection of trees and shrubs all well named. Indeed, of the various show grounds used by the Royal Horticultural Society, this seems to us the most convenient and beautiful. The spot known as the dell—a picturesque hollow, full of good specimen trees and shrubs—is quite a picture in its way. This, indeed, and several other spots in the park, are prettier scenes, in a landscape-gardening point of view, than we often find in private gardens of repute.

The ceremony of opening the exhibition will probably devolve on the Earl of Cork, Lord Lieutenant of the county, supported by the Mayor of Bath, the High Sheriff of Somersetshire, and other gentlemen of distinction. We understand that the Mayor of Bath intends to invite the Council of the Society and its officers to a grand banquet after the inaugural ceremony.

## THE KITCHEN GARDEN.

### CULTIVATION OF THE MUSHROOM.

BY JAMES BARNES.

WHERE I lived some fifty years ago there was a Mushroom house, heated by a blue and peat fire. The shelves were placed one above another for the reception of the material for the beds; cow-dung was collected from the fields, stable droppings were shaken out, turned and dried in open sheds, the beds were made, rammed tight, and spawned in due course; the whole was then covered with nice friable loam to the depth of 2 inches or thereabouts. This system was called "Oldacre's method." At that time it was considered a great feat among horticulturists to grow Mushrooms successfully; and I well recollect earnestly watching for them to spring up, which they did, very nicely, in about six weeks. Three years later I entered a large London market garden, now all built over. There, besides extensive Pine, Grape, Cucumber, and general forcing and plant culture, Mushrooms were largely grown, on pretty much the same principle as that just mentioned, only, instead of shelves, the beds were made on the floor against the back walls of sheds, along which flues ran, or in beds ridged in the centre, according to convenience. In winter a nice moist heat was maintained by placing hot stable manure inside, and often turning it over. In summer beds were similarly made in an underground cellar, and out of doors ridge beds. Indeed, we were at that time considered first-class Mushroom cultivators, of which there were very few about London, so that a good price was always obtained for our Mushrooms. My employer would never sell them under 1s. per pottle (that is, a Strawberry pottle) for the buttons, and a small flat punnet for the open or flat Mushrooms. At that time Mushrooms paid better made into ketchup, than when sold at 1s. a pottle. I have known them sold in quantities at that time from 2s. 6d. to 7s. 6d. per pottle, and when very scarce, even at half a guinea a pottle. I next undertook the management of a much more extensive market garden, on the Surrey side of London, where Pines, Grapes, Cucumbers, Melons, salads, vegetables, &c., were forced very early and extensively; Mushrooms had, however, not then been attempted at that place. I soon set about growing them, however, on a very extensive scale, and also the manufacture of spawn. I had now so simplified the Oldacre system that anyone could grow Mushrooms who could get a little stable dung and some fresh earth; good loamy holding or stiff soil certainly is best.

How I first got this knowledge was as follows: I was removing an old worn-out bed in dry weather, in the summer time, when I observed how the spawn had run into the earth, as well as into the muck or litter that had been wasted and trodden about near the beds. I at once asked myself, why take so much pains and trouble in preparing and drying the dung to make Mushroom beds? So I set about making fresh beds directly with dung from the stables, shaking out only a small portion of the longest dry litter, and intermixing with it a quantity of such earth as was at hand, ramming and treading it down as firmly as possible to the desired size and depth or height. In this way I at once secured the full properties of the manure and soil, and a genial heat, without a chance of burning or becoming too moist, or in the least exhausting the properties of the material through fermentation. Such a composition, in a genial situation, will oftentimes actually breed or produce spawn without using artificial spawn. Beds made on this principle always produce Mushrooms in abundance, of the finest and heaviest kind, and continue to bear or produce them for many months. After the beds have been in bearing for some time and are beginning to get dry, we always water with tepid clear manure-water, made or formed only from sheep, deer, or cow-dung; no chimney soot or lime is used for this purpose. It is astonishing the length of time a Mushroom bed may be kept in full bearing by this treatment. For the last thirty years I have made my beds entirely on the floor in sheds; I wheel in the stable dung fresh, and mix with it a sufficient quantity of soil, incorporating all well together, treading and ramming it firmly down, letting it remain five or six days; then shaking it up and intermixing it well together and if it is found fermenting too strongly, I add more soil

treading and ramming down as before. Very soon afterwards it is ready to spawn and ease with soil; when, a very gentle genial heat and moisture being secured, these properties are afterwards fully maintained. In this way much trouble and time are saved in collecting cow-dung, and in getting the stable droppings saved, as was wont to be done. Besides in the frequent turnings to which the dung used to be subjected its best properties were allowed to escape. In winter we make our beds, when finished and eased, about 16 or 18 inches thick, and in summer, about 6 inches less, thus securing Mushrooms every day in the year.

### ARTICHOKES.

THE Globe, or French Artichoke (*Cynara Scolymus*), is a valuable and wholesome vegetable, which can be obtained in good perfection for at least six months in succession. Commencing with the old-established plants that have been well protected through the winter, these will afford the first supply in May and June; and, for the next two months, crowns may be had from a planting of strong suckers made in March; and, for the end of summer and autumn, from a successional planting made in May. Another very good plan is to cut back, close to the earth's surface, a few old plants early in spring, and occasionally afterwards. These will produce a thicket of shoots, which should be early thinned by pulling and cutting the weakest, and allowing only a portion of the strongest suckers to remain. These will produce, in succession, nice young heads. The Artichoke, if cut when about half grown, possesses a very pleasant flavour, and is a very delicate vegetable, almost the whole of which is eatable; but, if the heads are allowed to attain to their full growth, or nearly so, they are not so fine in flavour, and have lost most of their tenderness, so that only the base of each scale and the base of the head are fit to eat; whereas the whole of the head of a young plant may be eaten and enjoyed. The Artichoke will grow very luxuriantly and rank in rich boggy land in summer, and is not at all a bad-looking plant in large borders and wild gardens, with its noble foliage of a kind of bluish green, and with its large heads of flowers of a Borage-like blue colour; but it will not stand our winter in wet quarters. As a kitchen-garden plant, it will grow on any kind of soil, if well manured, trenched, and pulverised; but no soil suits it better than a good, open, sandy, rich loam, trenched, and well manured. The plant is in its best perfection at the second and third year after planting. Plants are to be seen in some places standing in a half-starved state for years, producing nasty little, hard, bitter heads. This is why, to a great extent, no doubt, the Globe Artichoke is not so generally appreciated as it should be. Artichokes are best for table when cut at about half-growth, when they have attained their delicate, bitter-like flavour. Boil them quickly in clean water, with a good portion of salt added to it; serve hot, applying butter, pepper, and salt, according to taste. They may, however, be served with white sauce, and in other delicate ways, as may please individual fancy. In a clear open piece of good soil, well manured, deeply trenched up into rough ridges to get well pulverised and sweetened by atmospheric influences, free from trees and hedges, planted methodically—the first batch in March, and for succession another planting in May—and afterwards kept thoroughly clean and an open free surface maintained by often hoeing and scarifying the ground about them, a dozen stools will produce as many fine rich heads as double the quantity will do by the old-fashioned crowding neglectful system of planting. To plant properly, make choice in early spring of good strong suckers, taken off the stools carefully with a sharp strong paddle-trowel or Asparagus knife, with some root to them or heel of the old stool, to hold them in the ground; plant them singly 2 feet apart, in rows at least 4 feet apart, or in groups of three in triangles, at 4 feet apart at least in the row. Protect them as soon as planted against the sun and cutting winds, with the Seakale pots, at this season just out of use, or with evergreen boughs, or some other convenient protecting material. Those thus early planted will produce nice free crisp heads the same summer and autumn. If the stems also are cut close to the ground as soon as the heads are cut, new suckers will soon appear, and if duly thinned will produce a late crop; thus,

by treating the Artichoke systematically with a little method and forethought, a good supply of nice heads may be obtained in succession from May till October. This plan is much better than that of growing a large piece of Artichokes, and allowing them to come in in June and July, at one and the same time, by the cwt., when Peas, Cauliflowers, French Beans, Asparagus, Spinach, and a host of others of our most useful vegetables are in full season; and when the spring and summer vegetables are getting more scarce there are no Artichokes to succeed them. To say the least, it is a lack of forethought not to have them in full succession all the summer, without having a great glut of them all at once and when only a few are required.

B.

## WORK FOR THE WEEK.

### PRIVATE GARDENS.

**Flower Garden.**—After the flower and subtropical gardens have been furnished, there will probably remain many odds and ends that will prove useful for the decoration of herbaceous and shrubby borders, and which should now be planted in such positions in them as will set them off to most advantage. Peg down Petunias, Verbenas, old and "leggy" Pelargoniums, Tropæolums, &c., so as to render them as effective as possible. Bracken or small Beech pegs are excellent for this purpose. Have a stock of Lobelias in reserve to take the place of inferior kinds, which often appear where seedlings are used. Edgings of Cerastium should be gone over weekly, and all flowers cut off with a pair of shears; flowering shoots should likewise be picked off all plants of the variegated Polemonium caruleum, golden Feverfew, variegated Spiræa Ulmaria, and other plants grown only for the beauty of their leaves. Affix stakes to Dahlias, which, with the exception of the purple Zelinda and a few others of that class, require such support. A good supply of reserve plants for future stock should now be secured—for instance, Centaureas kept in pots during the summer time are better for propagating from than plants lifted out of the soil. Solanums, Wigandias, and various other sub-tropical plants, kept in pots and starved during summer, are also very useful for affording cuttings for the next season.

**Herbaceous Plants.**—These being now in great beauty, a little extra care should be bestowed on them. Lift such Hyacinths, Tulips, and Crocuses, as interfere with them, and spread them out to dry without removing any of the leaves. Cut over the decaying stems of Fritillarias and similar early flowering plants. Gather seeds of Scillas as soon as they are ripe, and sow them at once. To Hollyhocks, and some other plants that require support, apply strong stakes, but Campanulas, Delphiniums, Pentstemons, Antirrhinums, Pyrethrums, and some others of a similar character, look best when unsupported in that way. Transplant Primulas, kept in pots, on to a shady border, where they should be kept clean, and secure from slugs; *P. japonica* always grows better when planted out of doors than when grown in pots. A mulching of rotten manure, spent hops, cocoa-nut fibre, or leaf soil should be spread over the ground, and if its appearance on the surface is objectionable, cover it with soil. Phloxes like plenty of nourishment, consequently a little manure water should now and then be given them. Everlasting Peas, wintered in pots, may now be planted out, but in the case of Dodecatheons, &c., intended still to be kept in pots, a shady position on a bed of ashes is best for them, and upon no conditions should they become at any time perfectly dry. Remove decaying flowers, except in cases in which seeds are to be sown. Transplant biennials and perennials, and as soon as they come into flower rectify the nomenclature of Irises, Lilies, Pyrethrums, &c., the names of which are apt to get misplaced during the operation of transplantation.

**Conservatories.**—Plants under glass are now growing vigorously; therefore, cold draughts must be avoided as much as possible. There must, however, be plenty of ventilation, abundance of water must also be given, and shade of some kind provided as a protection to plants in bloom, the beauty of which soon becomes impaired if exposed to sunshine. Give weak manure water to gross feeding plants, and from specimens planted out in borders remove all superfluous shoots and suckers. Tacsonias, Passifloras, Bignonias, Habrothamnuses, Loniceras, Maréchal Niel Roses, and other climbers, must be frequently regulated in growth, not so much by means of shortening their shoots as by removing the weakest of them. Fuchsias trained

to rafters require thinning, and Clematises tying to trellises. Do not allow deciduous climbers to intertwine with evergreen ones, as they are apt to spoil the latter. Keep up a succession of Hydrangeas, zonal, show, and sweet-scented Pelargoniums, Fuchsias, Coleuses, Lobelias, Salvias, Cockscombs, Balsams, Schizanthuses, and similar plants, and transfer to frames or the greenhouse such plants as have done flowering. Heaths, and some other early-flowering, hard-wooded plants, may now be set out of doors on a bed of ashes, plunging the pots in cocoa-nut fibre, or some such material, to keep the roots cool and moist.

**Greenhouse Plants.**—Old plants of *Agapanthus umbellatus* will now be flowering abundantly, and should have plenty of water and a sunny position. Plants of *Hebeclinium ianthinum* should have been cut down after flowering, and should now be kept moderately dry for a time, unless it is necessary to force them early. Cut in hard-wooded Veronicas that have done blooming, so as to encourage fresh growth. Keep plants of *Lisianthus Russellianus* in a warm, moist place, and repeat them as often as they require it. Pot off seedlings of *Primula japonica*, and keep them out of doors, where they form stronger plants than if nursed under glass. Shift Staticeas as they require it, and, when they begin to flower, give them manure-water, or place a mulching of manure over the surface of the soil in the pots in which they are growing. Lemon-scented Verbenas and Fuchsias should be started into growth, as required; those already started should be kept pinched in, to make them bushy. Keep Carnations in a somewhat shaded house. Plants of *Kalosanthes* should now have some assistance in the way of stimulants, as should also Lilliums that have formed their flower-buds, and some other soft-wooded plants. Erythrinas in pots should be grown in a cool and light house near the glass; they require plenty of water, and their main branches should have supports of some kind to keep them in proper position. Bouvardias that were cut back after flowering should now be making good wood; they must, therefore, be kept moist and warm for some time yet. Persian Cyclamens should be kept in cool and shady frames, or against north walls; they should receive a little water during the summer months. *C. Coum*, and similar kinds, should also be kept moderately dry, but not too much so.

**Azaleas and Camellias.**—Azaleas that have done blooming, and which have had their seed-pods picked off, should be repotted if necessary, and put into a warm pit, where heat, moisture, and shade can be given them. Camellias also make good growth under similar conditions, as do also Citrons of various kinds. Pinching in should be practised freely until the plants have attained the form it is desired they should assume.

**Stoves.**—Ventilate, more or less, according to the state of the weather, and shade from strong sunshine. Keep the atmosphere moist by syringing not only the plants, but the stages and walls, and likewise by sprinkling the floor with water. Poinsettias should now be started into growth; they should be propagated by means of cuttings and eyes, and the young plants should be kept shifted on as they require it, and set near the glass. Plants of *Euphorbia jacquiniiflora* must be kept growing, and also near the glass, so as to ripen the points of the shoots. Pot on young plants of *Sanchezia nobilis*, *Scutellaria maciniana* and *Ventenatis*, *Pentas carnea*, *Linum trigynum*, *Monochaetum ensiferum* and *sericeum multiflorum*, *Conradenias*, *Eranthemums*, and others, using a compost of loam, thoroughly-decomposed manure, and a little peat. Increase the stock of *Achimenes* by means of cuttings; *Gloxinias*, by using good and well-developed leaves as cuttings; the fine-leaved *Begonias* in the same way as *Gloxinias*, and also by placing a whole leaf flat on the surface of a pan filled with silver sand and peat, and surfaced with sand, affixing the leaf thereon with pegs, cutting or breaking the ribs at intervals, and sprinkling some sand over the surface of the leaf; if kept damp and shaded, leaves treated in this way soon form buds at every break. The herbaceous kinds are best increased by means of cuttings. Keep *Epiphyllums* in a nice growing temperature, and *Eucharis amazonica* plunged in bottom heat, in a moist stove and flooded with water. Pot seedlings of *Cyperus alternifolius*, give them plenty of heat and moisture, and they will form, when one or two years old, fine plants for table decoration. Keep the *Dracænas*, *Crotons*, *Ananassas*, and other fine-leaved plants, near the glass, in order to bring out their colours, but preserve them from strong sunshine. *Dipladenias*, *Allamaudas*, and similarly habited plants, hitherto run along the roof just inside the glass, on threads, may be taken down as they come well into bloom, and trained so as more fully to exhibit their beauty.

**Suspended Baskets.**—Remove any plants that appear to be exhausted, and replenish with fresh material; rather, however, than lift out many of the plants, plant the basket afresh, retaining such as are in good condition. Ferns, *Selaginellas*, *Tradescantias*, *Begonia scandens*, variegated *Panicum*, *Asystasias*, *Achimenes*, some of the creeping *Ficuses*, &c., do well in baskets kept in stoves; and

for conservatory and balcony baskets take Ivy-leaved and sweet-scented Pelargoniums, brilliantly coloured Lobelias of the Erinus section, Petnnias, Mosembryanthemums of different sorts, Tropæolums, Isolepis gracilis, Gazania splendens, Lysimachia nummularia, Ivies, Musk, Convolvulus mauritanicus, and many kinds of Ferns and Selaginellas.

#### INDOOR FRUIT DEPARTMENT.

**Pines.**—Water abundantly, and sprinkle the plants overhead either with a syringe or through a watering-pot rose. Remove all suckers, except such as are required for purposes of propagation; in the latter case, they should be taken off and potted when strong enough. Plants ripening fruit should be kept rather dry, and in order to keep them as long as possible in good condition remove them to a cooler house.

**Vines.**—Give a little fire heat, and also a little ventilation at the same time, to Vines that are in flower; a genial and moderately low equable temperature is of great service to the setting of the fruit. Attend to the timely thinning of the berries and pinching of laterals. Apply stimulants to such as have set their fruit, but have not begun to colour. Shift into their fruiting pots all pot Vines intended for fruiting next year.

**Peaches and Nectarines.**—Where these have been gathered, give the trees a good syringing, the borders a thorough watering, and continue a little fire heat until the wood becomes perfectly ripe. Give up syringing in cases in which the fruit is beginning to colour; but, until then, syringe daily; tie in and thin the shoots, and put aside any leaves that happen to overlap the fruit, so as to give it a chance of becoming well coloured.

**Figs.**—As soon as the first crop has been cleared off, mulch the soil with manure, water freely, and maintain a warm, growing, moist atmosphere.

**Cucumbers and Melons.**—Give Cucumbers a good supply of manure-water, stop laterals, and only retain as many fruits as the plants can well bear. Keep Melons ripening fruit rather dry; but water abundantly those swelling. Use tiles or slates for putting under the Melons if they are grown in frames. Prepare plants to take the place of those now ripening fruit; or, after the fruit has been cut away, cut down the old plants to two or three eyes of the stem, apply a dressing of fresh soil over the old material, give a thorough watering, and increase the temperature, when the plants will again start freely into growth.

## SOCIETIES, EXHIBITIONS, &c.

### ROYAL HORTICULTURAL SOCIETY.

JUNE 18TH.

This was an unimportant meeting, except in the case of a few miscellaneous subjects, about which there was a certain amount of interest. The paucity of exhibits on this occasion was doubtless owing to the proximity of the society's great meeting at Bath. In the class of six Palms, Mr. Cole, of Ealing, was first, with half a dozen nice plants; and Mr. Fewel, Broad Green Lodge, Croydon, was second. In the nurserymen's class of eight Palms, Mr. Wm. Bull was first, with some very fine medium-sized plants of some of the newer sorts; and Mr. Aldous was second. Fuchsias formed the chief feature of the exhibition; but, amongst them, there was nothing remarkable, either in the way of kinds or cultivation. For six Fuchsias, Mr. J. Weston, Clapham Park, was first, with Arabella, Rhoderick Dhu, Conspicua, Lustre, Lucy Mills, and Enoch Arden. Mr. Walker, Gunnersbury House, was second; and Mr. James, of Isleworth, was third. For a dozen Fuchsias, Mr. James was first, with a group of small plants. In the class of six Pæonias, Mr. Parker, of Tooting, showed some well-bloomed specimens of the double-flowered kinds. The same exhibitor likewise showed a group of remarkably fine cut blooms, and also plants of the double-flowered Feverfews, likewise cut blooms of Irises. For a basket of plants arranged for effect, Mr. Hepper, Acton, was first, with a tastefully arranged vase, the stem of which was covered with Moss, studded with little Ferns. In the centre was a plant of *Auanassa sativa variegata*, and around it were *Caladiums*, *Begonias*, *Cockscombs*, *Isolepis gracilis*, the variegated *Panicum*, and similar plants. Mr. J. Aldous was second, and Mr. Cole third. From Messrs. Barr and Sugden came a collection of cut blooms of Irises, and a basketful of beautiful Lilies. Mr. Noble, Bagshot, sent a few plants of the pretty *Spiræa palmata*. Mr. W. Denning, Norbiton, furnished an excellent group of Orchids, including *Dendrobium Bensone* and *Parishi*, *Lælia majalis*, and *purpurata*, *Pahumbina candida* with several graceful little flower trusses, and well-flowered plants of *Acridis virens*, affine, *maculosa*, and *odoratum*. From Mr. H. R. Smith, Ealing, came a collection of very fine Balsams and a group of Fuchsias, including *Aneha*-blotched-leaved ones and several grafted forms. Messrs. Rollisson and Sons sent a group of beautiful seedling *Gloxinias*; and Mr. Linden, of Brussels, furnished some fine foliaged plants, viz., *Phyllotannum Lindeni*, *Curmeria picturata*, *Tillandsia tessellata*, *Anthurium crystallinum*, &c. Messrs. Backhouse and Sons, of York, showed a pretty

example of the Californian *Cyclobothra pulchella* laden with its curious and pretty yellow flowers. Mr. Dean, of Ealing, sent flowers of some pyramidal Stocks remarkable for purity of colour and the closeness and doubleness of their flowers; also blooms of Canterbury Bells including many shades of colour. Mr. Incombe, Combe Royal, Kingsbridge, sent blooms of a beautiful Sikkim *Rhododendron*, that thrives well in the open air in that part of Devonshire; and Mr. Croucher, gardener to J. T. Peacock, Esq., Hammersmith, sent a group of curious Agaves. From Mr. J. Edwards, gardener to Lady Prescott, Herne, Kent, came dishes of wonderfully large and fine Royal George and Violet Hatve Peaches, and also dishes of very fine Violet Hatve and Elrue Nectarines, as well as a brace of Cucumbers. Mr. A. Coulbourne, Woolhampton, sent a dish of Pitmaston Orange Nectarines, that were so large and fine as to be awarded a cultural commendation; the same exhibitor likewise showed a dish of the Japanese Loquat. From Mr. Wm. Tillery, Welbeck, came excellent dishes of Empress Eugenie, British Queen, and Lucas Strawberries. Mr. Cadger sent a fruit of his seedling Melon called Wrotham Park, a finely-flavoured white-fleshed medium-sized sort, with a beautifully netted white skin. Mr. Gilbert, Burghley, also sent a particularly good green-fleshed hybrid Melon, and Mr. J. Gardner, Elsham Hall, Brigg, contributed another seedling Melon. A dish of Apples in a good state of preservation was sent by Mr. Noble, Bagshot.

**First-class Certificates**—These were awarded to the following:—

- Gloxinia*, Brilliant (Rollisson), the flowers of which are brilliant scarlet and very fine.
- Gloxinia*, Rev. A. H. Bridges (Rollisson), a rose-coloured flower with a striped and mottled throat.
- Gloxinia*, Mrs. Fanny Wilder, the flowers of which have white edges suffused with scarlet.
- Echmea bracteata* (Rollisson), a strong growing very fine Bromeliad.
- Fancy Pansy, Richard Dean (Downie, Laird, and Laing), large blotches, with pure yellow margin, and chocolate upper petals.
- Fancy Pansy, J. B. Downie (Downie, Laird, and Laing), dark maroon blotches and chocolate ground.
- Fancy Pansy, Mrs. Nelson (Downie, Laird, and Laing), all the petals have large blotches of white and white edges.
- Fancy Pansy, Piontee (Downie, Laird, and Laing), a most peculiar flower, with very large dark maroon blotches, veined with same colour on a straw ground.
- Fancy Pansy, Thos. Granger (Downie, Laird, & Laing), a superb flower, velvety brown with dark maroon blotches.
- Fancy Pansy, Mrs. Michie (Downie, Laird, and Laing), large dark violet blotches, broadly edged with white.

## COVENT GARDEN MARKET.

JUNE 20TH.

The supply of both home grown and foreign fruits and vegetables, though on the increase, is not greater than the demand. Great quantities of really good Pine-Apples have arrived from the Bermudas and the West Indies. Grapes are excellent, as are also Peaches and Nectarines. Forced Strawberries are nearly over; but outdoor ones are expected in quantity next week; some from the south-western counties have already appeared in the market. France and Spain are supplying us with salading, Turnips, Carrots, Artichokes, Cherries, Apricots, Plums, &c. Spanish Tomatoes are also plentiful, but in point of flavour they are inferior to English produce. Of flowers there is a large supply, particularly of Roses, *Calceolarias*, *Hydrangeas*, *Pelargoniums*, Finks, Pansies, blue *Centaureas*, &c. There are also fine trusses of *Stephanotis*, Orchids, and other choice stove and greenhouse plants.

**Prices of Fruits.**—Apples, per doz., 2s. to 3s.; Apricots, 2s. to 4s. per doz.; Coles, per lb., 2s. to 2s. 6d.; Cherries, per box, 2s. to 4s.; Gooseberries, per quart, 3d. to 6d.; Grapes, hothouse, per lb., 6s. to 15s.; Lemons, per 100, 6s. to 10s.; Melons, each, 4s. to 10s.; Oranges, per 100, 6s. to 11s.; Peaches, per doz., 18s. to 36s.; Pine-Apples, per lb., 8s. to 12s.; Strawberries, per lb., 6s. to 12s.; Walnuts, per bushel, 15s. to 30s.; ditto, per 100, 2s. to 2s. 6d.

**Prices of Vegetables.**—Artichokes, per doz., 3s. to 6s.; Asparagus, per 100, 3s. to 6s.; Beans, Kidney, per 100, 1s. 6d. to 2s. 6d.; Beet Red, per doz., 1s. to 3s.; Broccoli, each, 6d. to 9d.; Cabbage, per doz., 1s. 6d. to 2s.; Carrots, per bunch, young, 1s. old do., 8d.; Cauliflower, spring, per doz., 4s. to 8s.; Celery, per bundle, 1s. 6d. to 2s.; Coleworts, per doz. bunches, 4s.; Cucumbers, each, 4d. to 1s.; Endive, per doz., 2s.; Fennel, per bunch, 3d.; Garlic, per lb., 6d.; Herbs, per bunch, 3d.; Horseradish, per bundle, 3s. to 4s.; Lettuce, per bunch, 6d.; Lettices, per doz. 1s. to 2s.; Mushrooms, per pottle, 2s. to 3s.; Mustard and Cress, per punnet, 2d.; Onions, per bushel, 8s. to 12s.; button, per quart, 1s.; Parsley, per doz. bunches, 6s.; Parsnips, per doz., 9d. to 1s.; Peas, per quart, 2s. to 3s. 6d.; Potatoes, new, per lb., 2d. to 4d.; Parsishes, per doz. bunches, 1s. to 1s. 6d.; Rhubarb, per bundle, 9d. to 1s.; Salsify, do., 1s. to 1s. 6d.; Scorzonera, per bundle, 1s.; Shallots, per lb., 6d.; Spinach, per bushel, 3s.; Turnips, old, per bunch, 9d., young do. 1s.

## ANSWERS TO CORRESPONDENTS.

**BLUE CINERARIAS (V.)**—Seeds saved from these generally come pretty true to their respective kinds, provided the plants are carefully kept away from all others whilst they are in bloom.—**ROSE BUDS (Somerset House).**—Mr. Geo. Paul, to whom we submitted your case, is of opinion that ants are the culprits, as he has found them eating Rose buds after, he says, they had finished all the aphides which they could find upon them. Paraffin oil is spoken of as a remedy.—**PAINT (Conservatory).**—It is useless to paint over old paint, especially in your case. First strip off the old paint with hot irons, let the wood be thoroughly dry, and then apply three thin coats of pure white-lead.—**NAMES OF PLANTS (G. W.)**—1. *Spiræa Reevesiana*; 2. *Lonicera tatarica*; 3. *Epipactis latifolia*.—(Violet Hill.)—Kindly send us fresh specimens.—**PRIONICALS (W. W.)**—*The American Agriculturist*, *The Cultivator*, *Health and Home*, *The Tribune*, *Moore's Rural New Yorker*, and *The Gardener's Monthly*, Trübner & Co., Ludgate Hill.—**FREMONTIA (D. S.)**—This flowers beautifully against a wall in the south of England, and will survive out of doors during the winter if its roots are protected from frost.

## THE GARDEN.

"This is an art  
Which does mend nature: change it rather: but  
THE ART ITSELF IS NATURE."—*Shakespeare.*

### RIPENING THE WOOD OF PLANTS.

In the management of exotic plants of all kinds it is found that too little attention is paid to the proper maturation of the young growth, and that in consequence the flowering principle, and of course the fruiting also, is thus curtailed. This is more especially the case with the finer kinds of stove and greenhouse plants. We endeavour to grow them vigorously, but at the same time too frequently forget that strong growth and its complete maturation are not in this climate synonymous terms. Many good growers of hard-wooded plants object to placing them in the open air at all, but I am not of that number. Turned out upon the lawn, greenhouse plants may be made to serve a very interesting purpose, and to impart quite a new and exotic feature to the flower garden, while at the same time every facility is afforded for training the plants and otherwise attending to them. My plan is to plunge the plants at the proper time in groups, in which good specimens produce a fine effect. Of course, in such arrangement care must be taken in preparing the holes for the pots to secure proper drainage, and also by placing some lime-rubbish or cinder-ashes in the bottom, to prevent the ingress of worms. Plants so arranged have the advantage, so much to be desired, of a cool bottom, without the roots or pots being exposed at one time to scorching heat, and at others to cold chills. These are great points; for though, to secure the thorough maturation of the wood, full exposure is necessary for the branches, nothing is more injurious to tender-rooted plants than an undue exposure of their pots to a dry atmosphere. In exposing tender plants, however, for the benefit of the atmospheric influence, the fact must not be lost sight of, that while some plants require thorough exposure in order to mature their wood and set their flowers, others are better for partial shade; and many, as among our choicest Heaths and Chorozemas, do not set their flowers until the completion of their growth, in the very depth of winter, or even in spring. Even these, however, are benefited by full exposure in early autumn; for it never must be forgotten that, though a plant may not complete its growth before winter sets in, it may, by judicious exposure in the autumn, so elaborate and store up organizable matter as to induce almost invariably the flowering principle at the proper season. To secure a healthy bloom in hard-wooded plants of all kinds, the first point is to induce healthy and vigorous growth, and then to secure its proper maturation. This can only be achieved by proper exposure, not necessarily out of doors, but often under glass, by placing the plants in the lightest part of the house, and also by admitting a free current of air to pass through them. A plant may be starved into bloom, but that is not always the best way of effecting that object. What we

want in plants difficult to bloom is healthy root-action, and with it firm, strong, short-jointed wood in proper season; then mature it properly, and bloom is certain. I once purchased a specimen plant of *Erica depressa*, of a variety which, it was said, would never bloom properly. The plant, though healthy-looking, was exceedingly weak, through an attempt having been made to starve it into bloom. I took an opposite course, potted it, and got it into good growth; and the following autumn almost every point or shoot was studded with flower-buds. Through the autumn, from June until September, the plant was placed in the full sun, the pot being plunged in cinder ashes, and the result was perfectly satisfactory. Now this is confessedly one of the most difficult Heaths to bloom well; but I am quite sure the failure arises more from starving than from liberal treatment. Some good cultivators object, as I have said, to exposing many of the finer kinds of greenhouse plants to the open air at all, more especially the finer kinds of Azaleas and *Eriostemons*. I do not like to expose them until their growth is completed, and their blooming rendered quite certain; but then, I think, a

few weeks in the open air, more especially if the plants are not exposed to drenching rains, is very beneficial. Great care, however, must be taken to get the flower-buds of such Azaleas as *Gledstanesi*, *variegata*, and the like, plump and full before the plants are turned out; but the free-growing varieties bloom almost under any circumstances. The dews and gentle rains of autumn have a very invigorating effect upon plants, and, if, during heavy rains, the plants are laid upon their sides, they are materially benefited, by the underside of the foliage being properly washed, and to some extent cleared of insects and bad leaves.

W. A.

*Phoenix reclinata.*

### PHENIX RECLINATA.

This elegant plant like its congener, the Date Palm (*P. dactylifera*), is a free and robust grower, and makes a useful decorative

plant for a warm conservatory, and occasionally for the ornamentation of apartments. Its plume-like leaves are very gracefully curved, and being of a soft glaucous green colour, they contrast well with Ferns or other darker coloured foliage plants. Our illustration gives an excellent idea of the beauty of this Palm, just at the period when it assumes its true character and is most useful. Like its allies it succeeds well in good turfy loam, and when growing requires an abundant supply of water. It is propagated from seeds sown in light earth, the pots being plunged in a mild bottom heat and kept moderately moist until germination takes place.

### RHODODENDRONS IN BASKETS.

At the Maldon Show the other day, a capital effect was produced by a series of Rhododendrons placed in small round baskets and put on one of the tables. The brown of the Willows contrasted admirably with the glossy leaves and glowing colours of the gorgeous trusses of blossom. It struck me on the spot that these simple baskets might be very useful for forced plants in the conservatory, and in the furnishing of

large houses with forced Rhododendrons. There is often a difficulty in finding pots large enough to take the balls. As far as the mere act of forcing is concerned, it is not needful either to pot or basket the plants. They do better with the balls simply plunged in a gentle bottom heat of tan or decaying leaves. I have found this mode of forcing large Lilacs, and other hardy plants, equally successful. Cut out a good ball, and plunge it in bottom heat. There is no fear of overheating, and the heat hits, excites, and quickens the roots, and starts the sleeping buds at once. A good deal of time is gained by dispensing with the pots; but, when the plant is wanted for conservatory, hall, or staircase decoration, it must be potted or put in a basket. The latter is by far the handiest, cheapest, and best method. Baskets may be had of any diameter and depth, and they are light and easily moved. Their relative flatness compared with pots, too, enables us to dispense with the leggy look that often mars the form of forced shrubs. As to watering, if the plants are to remain in the house, the baskets must, like pots, have an earthenware or tin saucer. And, then, what facilities wicker-work offers for the adornment of its sides! Should the brown Willow be offensive to the eye of taste, how easy to fringe it with Maiden-hair Fern or Lycopodium as we finish the process of basketing! Supposing one had to decorate a suite of rooms during the season of Rhododendrons in the open air, what could be easier than to go into the grounds, lift a score or two of plants, and basket them for the night or the week, and replace them when their beauty indoors has come to an end? Then those who study durability in all things, could easily have iron baskets made for these purposes. I use this word "basket" advisedly, because I mean something much cheaper, lighter, and even better for these uses than vases. The vase is always too prominent, and, in many cases, it eclipses its occupant. It is too high, too heavy, too elaborately designed or carved; its maker has determined to place it first, and we cultivators want the plants first, and a vase or basket to take the very subordinate place of holding or displaying the plant to the best advantage, while, to some extent, it is itself concealed. For this purpose, iron baskets, or the common round packing baskets, with which we are all familiar, would be admirably adapted for the holding of forced Rhododendrons, Ghent Azaleas, Deutzias, bush Roses, and for many other purposes: while for temporary uses the common brown wicker baskets might take a useful cultural, and even ornamental, part in most gardens. As the baskets get too old for showing the plants in, they might be used for growing them in until they flower, and by growing them in a size smaller than they are to be exhibited in, there would be no disturbance on transferring them from the forcing bed to the display room or house, while the interstices between the baskets could be furnished as already proposed, or fringed with the drooping leaves of the *Isolepis gracilis*, Ivy-leaved Geraniums, Ivy, variegated Periwinkles, or delicate Lobelias, showering down azure and white.

D. T. FISH.

**Orchids in Flower.**—Amongst the Orchids at present in flower at Kew, may be noticed *Calogyne ochracea*, bearing numerous erect spikes of white flowers, the three-lobed lips being blotched with lemon yellow, and the blotches themselves margined with bright red. The pseudo-bulbs are fluted or ribbed, and each bears two oblong leaves. The flowers are delicately perfumed. *Trichopilia Galeotiana*, a curious species, with linear pseudo-bulbs, each bearing a solitary oblong leaf. The flowers are borne profusely, and differ from those of most other species in the genus, being of a pale sulphur yellow, the disc of the convolute lip being of a bright orange. This plant has been exhibited at the London exhibitions as *T. trialytic*. *Oncidium lanceanum*, a very fine old Orchid, rather difficult to cultivate, is also producing a nice branched spike of its large and richly tinted flowers. Of this *Oncidium* there are two varieties, in one of which the lip is almost white. If the flowers of both kinds are kept free from damp, they will last in good condition for several weeks at a time, and when produced in abundance, which seldom happens, they are very effective. As a curiosity, *Epidendrum campylostylis* is well worth notice. It has flat pseudo-bulbs and foliage very much resembling some *Trichopilias*, and bears an erect ten to twelve flowered spike of dark brown and yellow flowers. The backs of the sepals and petals are of a peculiar mealy hue, and it is quite distinct from any other species in the genus.

#### CYPRIPEDIUM DOMINIANUM.

SOME of the finest Orchids in cultivation owe their origin to the art of hybridisation, and among such triumphs of skill may be classed the many beautiful hybrids that have from time to time been raised in the Royal Exotic Nursery, Chelsea. The interesting variety of *Cypripedium*, of which the next page presents an illustration, is one of the latest hybrids obtained by Mr. Dominy, in compliment to whom it has been named by Professor Reichenbach. Its parents were the long-petaled *C. caudatum*, already described in our columns, and the pretty little *C. (Pearcei) caricinum*, and between these two species it is as nearly as possible intermediate. The leaves are broader than those of *C. (Pearcei) caricinum*, but narrower than those of *C. caudatum*. In habit the plant most resembles *C. caricinum*, but the flowers are much larger and brighter coloured. The petals remind one of similar appendages in *C. caudatum*, but they are twisted spirally like those of *C. caricinum*. The flowers, which are produced two or three together on tall scapes, are of a greenish yellow colour, shaded with reddish-brown and spotted with purple. The staminate and the basal portions of the petals are densely set with stiff hairs. Mr. Dominy has been very fortunate in his attempts at hybridising *Cypripediums*, having obtained two varieties prior to the one now described, viz., *C. vexillarium*, and *C. Harrisianum*, the latter being a very profuse bloomer, the result of a cross between *C. barbatum* and *C. villosum*. Apart from the beauty belonging to these hybrids as decorative plants, they are interesting as illustrating the near relationship or affinity that exists among species. The *Cypripedium* now figured grows well in an intermediate house, treated like others of its class, and, as it flowers in tolerable profusion, it is a welcome addition to this interesting group of Orchids.

F. W. B.

## THE GARDEN GUIDE.

### SUFFOLK.

#### ELVEDON HALL.

This has recently been rebuilt and furnished in regal style for his Royal Highness the Maharajah Dhuleep Singh. The house is surrounded by a small park, and though much of the property is little better than blowing sand, yet plantations of Scotch Firs and others abound in all directions. Until quite recently, there has been but a very small garden at Elvedon; the kitchen and flower gardens and pleasure grounds being more like those belonging to a villa residence than a princely house; a great part of the flower garden, also, used to be an aviary, where the gay-coloured birds of India plumed themselves and displayed their brilliant hues, rivalling the flowers themselves in beauty. A new kitchen garden has, however, recently been formed, and some fine Vineries and other glasshouses have been erected. The flower garden and pleasure grounds, too, are in course of formation, and it seems probable that Elvedon will soon be surrounded by gardens worthy of the richness and splendour that characterise the new residence. His Royal Highness is fond of planting, and most trees and shrubs grow well on the light land around the house, provided it is trenched and manured. The situation in which the house stands is flat, and there is little landscape beauty within reach. Still capital, skill, and taste will doubtless, in a few years, render the gardens of Elvedon Hall worthy of their royal owner.—The Maharajah Dhuleep Singh; gardener, Mr. A. McArthur. Three and a half miles south-west of Thetford.

#### EUSTON HALL.

This is situated on the side of a magnificent park of over 1,400 acres, extending nearly two miles along the banks of the river Thet, which is crossed by a wooden bridge close to the mansion. The scenery is rich and beautiful, reminding one of Bloomfield's "Farmer's Boy," in which it is said, "the woods and groves in solemn grandeur rise." On the southern side of the park Fakenham Wood covers over 300 acres, and is one of the largest plantations in the country. Most of the more elevated knolls are crowned with wood, which apparently adds depth to the lower portions—they can hardly be called valleys. What is called "the Duke's Walk" starts from near the house, and proceeds in a straight avenue of great width right away to Newmarket. The late Duke of Grafton was fond of planting and rearing trees and shrubs. Both the park and the estate generally are, therefore, well wooded. The mansion, which is of red brick, stands very little above the water level. The Thet is here widened out into a lake. Immediately in front of the house

is a geometrical garden; then, on one side, an old French or scroll Box garden, flanked by glasshouses and walls, and then the park, richly clothed with trees, rises and rolls away beautifully in the distance. Nearer to the river, a series of lawns, shrubberies, rooteries, and comparatively wild gardens stretches away to a considerable distance, until they merge into the park and plantations. On an elevated knoll in the park stands a temple or banqueting hall, commanding fine views of the surrounding scenery, and forming a striking object for miles around. It was constructed from a design furnished by Kent. The kitchen gardens at Euston are large, occupying a good many acres, and are enclosed with fine walls. There are some old, and several very fine new Vineries. A large portion of the ground is devoted to the rearing and growth of forest trees, for the making up of old, and the furnishing of new, plantations. On various parts of this fine estate Scotch Firs and Spruces are used for forming roadside hedges; these do exceedingly well on light soils, and form dense lines of sombre beauty, giving a unique character to the landscape. Altogether Euston Hall has a dual air about it; the house is massive and striking, and the park magnificent.—The Duke of Grafton; gardener, Mr. Lowe. Four miles south-east of Thetford, ten miles north by east of Bury St. Edmunds.

**OAKLEY PARK.**

This is one of the richest and most beautiful seats in the county of Suffolk. The park is finely undulated, richly wooded, and contains about five hundred acres; part on one side, and part on the other, of the charming little river called the Ouse, that runs along the valley. The mansion is an elegant Grecian structure, of noble outward proportions and rich internal arrangements. The banqueting hall is filled with the choicest statuary, and a gallery 80 feet long is supported by a series of marble columns of exquisite beauty and symmetry. It overlooks the lovely valley of the Ouse, and is surrounded by fine pleasure grounds rising from the house and sweeping away in rolling green lines of beauty, embellished with statuary, fine trees and shrubs, and glowing with the brilliant colours of flowers. There is also a small garden immediately in front of the house. The kitchen garden, which is some way off on a higher level, is well furnished with fruits and vegetables, and a nice range of fruit houses. Timber grows freely in the park which is richly clothed with Oaks, Beeches, and other trees of great age and size. Altogether Oakley Park is a princely residence, the timber and other associations linking it to olden times, while the

gardens and their keeping are fully abreast of modern taste and the most recent horticultural improvements.—Sir Edward Kerrison, Bart.; gardener, Mr. William Robins. Three and a half miles from Eye, five miles E.S.E. of Diss, and six miles S.W. of Harlestone.

**BROOME HALL.**

This is a fine old mansion, said to have been built in 1590, and some portions of the house still exhibit fine specimens of the old English style of architecture. It is approached through a fine avenue of Oaks, far too rare in this country—the home of the Oak. In leaf and bole we have hardly any tree better fitted for avenues than the Oak, and yet it is comparatively seldom used for that purpose. The house is well shut in by surrounding woods plantations, and pleasure grounds, and skirting its base are terrace and other gardens, in character with the style of the building. A low retaining wall is richly furnished with Tea and other Roses. Then follow terrace-walks, fences of shrubs, geometrical flower gardens, &c., richly furnished and well kept. There is also a useful series of plant houses here, well furnished with fine foliaged stove and greenhouse plants. There is little or no kitchen garden, and no fruit houses at Broome Hall, as it is within an easy drive of Oakley Park, and also belongs to, and is occasionally occupied by, Sir Edward Kerrison. Broome is, therefore, to a great extent, the plant place for Oakley, and Oakley the fruit and vegetable garden for Broome.—Sir Edward Kerrison, Bart.; gardener, Mr. Peacock. Two miles north of Eye, four miles south-east of Diss.

**FINBOROUGH HALL.**

This is a handsome white brick building, erected about eighty years ago. It stands on a charming site—almost the highest part of a park of 200 acres—commanding fine views of a valley watered by a rivulet that joins the Gipping and Orwell near Stowmarket. The park is beautifully undulated and well wooded. It is also skilfully planted with clumps of trees, and some portions of it are bounded by thriving plantations. The gardens around the house are pretty, and extremely well furnished and kept. Conifers do well at Finborough, the soil being a good loam, and there are many fine thriving specimens around the house. Tea and other Roses are plentiful and healthy. The kitchen garden has been recently rewall in the most substantial manner, and well nigh remade. It is a noble garden, and the walls are rapidly being furnished with fruit trees of all the best varieties.—R. J. Petteward, Esq.; gardener, Mr. Henry Southgate. Three miles west by south of Stowmarket.

Dominy's Lady's Slipper (*Cypripedium Dominionum*), p. 20.

## THE FLOWER GARDEN.

### LILIES PAST AND PRESENT.

#### GROUP I (EARLIEST FLOWERING KINDS).

It may be interesting to know which Lilies now in cultivation were grown and described by Parkinson 250 years ago, and a comparison of the time at which some of them bloomed then with that at which they flower now may also afford an answer to the oft-repeated question—"have not our seasons changed?" The names quoted are taken verbatim from Parkinson's "Paradisi."

1. "Martagon pomponcum, sive Liliū rubrum, vel Liliū Macedonicum, the early red Martagon" of Parkinson, who adds, "Time of flowering, end of May," which corresponds exactly with the time of flowering in 1872, but ten days earlier than in 1873. (*L. pomponium* of "Bot. Mag.").

2. *Martagon pannonicum*, sive *exoticum flore spadiceo*, the bright red Martagon of Hungary" (*Liliū carniolicum*, notable in the auction mart, or, as the Americans would call it, the Two dollar Lily). Parkinson says he found very little difference between this Lily and the preceding one; an observation which corresponds with my own experience; the footstalk of the flower is longer, and the leaves are a trifle broader than in the preceding kind, but in other respects the two plants are alike.

3. "*Martagon luteum punctatum*" (*Liliū pyrenaicum* of the "Bot. Mag."). This differs from No. 1 in being yellow.

4. *Liliū pumilum eruentum*" (*Liliū tenuifolium* of the "Bot. Mag."). "This kind," says Parkinson, "sometimes yields double flowers," but of this I have no experience; I do not find the fact recorded anywhere else. Some of your readers may be able to furnish information on the subject.

5. *Liliū monadelphum Szovitzianum* (*Colechicum*). With this Parkinson was evidently unacquainted; amongst early flowering Lilies it is a prince—fair in form and noble in bearing, with a colour varying from delicate lemon to rich canary, some profusely and others sparsely spotted.

6. *Buschianum* of Loddidge's "Bot. Cabinet." A charming early flowering dwarf species, evidently a congener of *sinicum* of Lindley, *concolor*, *concolor angustifolium*, *parthenium*, &c., of other authorities, but a little more robust.

7. *Davuricum*, supposed by Mr. Baker to be the parent of the European Red Lilies, now offered in the trade under the names of *umbellatum*, *atrosanguineum*, *fulgens*, *Vulcan*, *Rubens*, *fulgidum*, &c. From these it differs mainly in the foliage being more slender, and the umbels of flowers being not so large. This section is no doubt "*Liliū aureum*, the golden red Lily," of Parkinson.

8. *Davuricum* var. *Vulcan*, rich crimson, shading down to orange, and generally without spots.

9. *Davuricum* var. *Rubens*. This differs from No. 8 only in being spotted.

10. "*Bulbiferum eruentum*" of Parkinson. This is a good distinct species; colour rich crimson, with bulblets in the axils of the leaves.

11. *Thunbergianum brevifolium*; colour rosy-apricot, spotted towards the bottom of the petals. I found this amongst some freshly-imported Japanese Lilies.

12. *Thunbergianum leopardinum*. The colour of this resembles that of No. 11, but it is spotted all over to within half an inch of the tips of the petals; not in commerce.

13. *Thunbergianum eruentum maximum*, rich blood-crimson; leaves long; flowers very handsome; not in commerce.

14. *Thunbergianum Barri*. This handsome variety came amongst some imported bulbs of *auratum*; colour rich crimson, profusely spotted with black; petals beautifully recurved. Not in commerce.

All these Lilies are extremely handsome conservatory plants; cultivated under glass, their beauty is enhanced, the foliage more delicate, and the colours more refined than if the plants are grown out of doors. I except from this general remark Nos. 1, 2, and 3, on account of their odour.

PETER BARR.

12, King Street, Covent Garden.

### AQUILEGIA GLANDULOSA GIGANTEA.

THIS lovely Columbine certainly ranks amongst the most handsome of all hardy herbaceous plants; and no garden, whether large or small, should be without a bed or clump of it. It is now in full flower here, and has been in beautiful condition for the last fortnight or more, and the effect produced by its large blue and white flowers is very remarkable, and exceedingly pleasing, whether as seen from a distance, or when subjected to closer examination. The variety called *gigantea* is an improvement upon the old and well-known *Aquilegia glandulosa*, which is somewhat difficult to grow and flower satisfactorily in some soils and situations, a remark which does not in any degree apply to its variety *gigantea*, which is of easy cultivation, and of a robust and vigorous habit of growth. Like many other flowering plants it is much more effective when grown *en masse*, or in the form of a bed or clump, than when seen in the form of an isolated specimen, but in whatever way it may be grown it is exceedingly beautiful. It reproduces itself perfectly true from seed, if no other plants of the Columbine family are grown in its vicinity. And if seeds of it be sown now in pans or pots, and placed under glass in a pit or frame where they can be shaded from the noonday sun, they will germinate freely. When the young plants are large enough to handle, let them be pricked out upon some shady border or similar situation, until about the first or second week in October, when they may be transplanted into a bed of moderately rich light soil, where they are intended to flower, which they will commence to do about the third week of next May. They will, however, flower more profusely and produce larger blooms during the second season than the first, and I may add that they are exceedingly useful for cutting for glasses, &c., in which their peculiar and beautiful colours are always held in the highest estimation.

P. G.

Culford, Bury St. Edmunds.

### JESSAMINES.

THESE are distinguished by their sweet odour; particularly *Jasminum gracile*, *undulatum*, *azoricum*, *Sambac*, *officinale*, *grandiflorum*, *fruticans*, and *odoratissimum*. In former times, *J. Sambac*, and particularly its double-flowering variety, formed prominent objects in stoves, on account of their free blooming character. The greenhouse species, *J. officinale*, *grandiflorum*, and *odoratissimum*, were also held in high estimation. Those that require the protection of glass may be grown either in pots, or, what is still preferable, planted out and trained around pillars, &c., where they enjoy all the sun and light possible. A compost of equal parts of peat, loam, and well decomposed leaf-mould, mixed with silver sand, accelerates their growth. The size of the pots entirely depends on the size and vigour of the plants; however, as the roots naturally spread on the surface, shallow and wide pots are preferable to narrow deep ones. During summer, when growing, the *Jasminum* delights in a high temperature, and it should have plenty of water; but in winter, during its period of rest, it likes a comparatively low and dry atmosphere. The best time for repotting is the spring, when the roots, as well as the old wood, are pruned back. *Jasminums* are propagated by cuttings, placed under a bell-glass, in the common way. As regards temperature, *Jasminums* may be arranged in three classes, according to the latitudes of which they are natives. 1. Tropical, requiring the temperature of a stove; 2. Intermediate, the temperature of a greenhouse; and 3. Such as bear the winters of our climate out of doors. No doubt *J. officinale*, though it is the most common, deserves to be more generally cultivated than it is, as it is perfectly hardy and grows and flowers freely trained to a wall with a south aspect. *Jasminum grandiflorum*, though generally grown out of doors, is apt to suffer from frost, if not carefully protected; this is the best for early forcing. *Jasminum fruticans*, from the south of Europe, stands out in a sheltered position during winter, and when covered with its yellow fragrant flowers is a great ornament to our gardens. *J. humile*, a dwarf kind, as its name implies, is hardy, and flowers profusely. *J. heterophyllum*, *pubigerum*, and *revolutum*, from the East Indies (Nepal and Hindostan), are generally hardy, though the young shoots suffer sometimes in severe winters. *J. revolutum* and *J. nudiflorum* seem to be the hardiest of all, and the latter is one of our most valuable winter-flowering plants. Mixed with Ivy against a wall, where its cheerful round yellow blossoms, each as large as a shilling, are backed up by green leaves, the effect which it produces early in the year is quite charming.

DELTA.

## THE GREAT REED.

(ARUNDO DONAX.)

WHEN well grown this is admirably adapted for moist low-lying portions of the lawn or pleasure grounds, or for moderately sheltered situations in the vicinity of ornamental water. There are few hardy foliage plants that rival this in stately dignity after it becomes thoroughly established, either as planted alone, or when grouped with Pampas Grass, *Chamerops humilis*, or the larger *Yuccas*, all of which grow luxuriantly in our warm southern counties, and are invaluable to the horticulturist, enabling him to add charming variety of form to the garden landscape, and to tone down the glaring colours of our chromatic flower beds, with forms that partake somewhat of semi-tropical grandeur. The plant we are now more particularly alluding to is rather difficult to establish in some localities, and on dry, barren, or sandy, soils it is as well to excavate 3 or 4 feet deep and fill in with a load or two of rich mucky loam, in which it is generally found to thrive most luxuriantly if well supplied with water. Our illustration gives an excellent idea of the portly appearance assumed by this species. Among other places where this plant succeeds well in the south, we may allude to the grand proportions which it attains at Syon House. It grows there from 9 to 10 feet high, in dense masses, nearly as much in diameter, and forms a truly imposing object, none the less beautiful because uncommon in the majority of gardens. It is easily propagated by dividing large clumps, or the thick caudex-like stems may be cut down and thrown into any tank or pond where they will quickly emit growths from the latent axillary buds, and, after these are rooted, they may be grown on and established in positions where they are to remain. *A. Donax variegata* is a dwarfier growing plant, rarely exceeding 2 or 3 feet in height, each leaf being striped with creamy white. This variety succeeds in our warm sheltered gardens in the south, but it does not possess the stately appearance of the green-leaved species. The variegated form is, however, simply invaluable for the flower garden, either in the centres of beds grouped with the choicer hardy plants, or isolated on the turf. It should have a well drained position, a deep warm soil, and a slight protection over the roots in winter. In Spain, and countries possessing a similar climate, the stems of this form of *Aruno Donax* attain a considerable height, and the leaves are broader and better variegated than with us.

The Great Reed (*Aruno Donax*).

**When to Transplant the Pampas Grass.**—M. May, in a recent letter to the *Revue Horticole*, remarks that he has frequently heard persons complain of their want of success in transplanting the Pampas Grass, nearly all the cases which were related to him involving the quickly-succeeding death of the plants. The reason of the failures, he states, is that they were transplanted at an improper season, viz., during the time of rest, when, as a rule, none of the Monocotyledonous plants like to be disturbed. In addition to this, the plants are usually lifted with an insufficient ball. If, on the contrary, the plants are lifted in May or June, replanted immediately, and copiously watered, there is little fear of failure. As an instance, M.

May states that one of his friends transplanted in this way thirty very strong tufts of the Pampas Grass early in June. Not one of the plants was lost; they appeared to recover almost immediately, and flowered the same year, just as well as if they had not been disturbed.

## NAMES OF NEW FLOWERS.

IN old times there were poets or scholars who baptized flowers—why should the new ones receive either hard, ugly, polysyllabic Latin or Greek names, or foolish and unmeaning ones, when every blossom of them deserves so well a simple, expressive, and charming title? Besides, to get a new "sport" well known and popular, a becoming title is half the battle. The astronomers, with their comets, stars, and asteroids, are far wiser—they never find out a stranger orb in the sky but they affix the cognomen of some graceful nymph or goddess to their discovery, and when a courtier sage some while ago

started a bad new fashion by calling the remotest planet of our system *Georgium Sidus*, his silly flattery was very properly cancelled, and everybody now knows that distant world under the better name of *Uranus*. A proposition has lately been made to send the raiser of new *Pelargoniums* and *Roses* to Homer for his nomenclature. If gardeners had time to study entomology, they would find that this would be poaching on the preserves of natural history; for the butterflies have long been called after the heroes and heroines of the "Iliad" and "Odyssey." *Agamemnon* is a magnificent lepidopteran, all emerald and black velvet; *Polydamas* is a crimson and gold wonder from Brazil; *Menelaus* stands godfather to a gorgeous azure and brown butterfly; and all the others are familiarly known to the collectors under these two heads of Trojans and Greeks. The idea, however, is a good one, and might be very well carried out by resorting to our own poets. Shakespeare, Chancer, Spenser, and the other best known English bards would supply names for as many really new and lasting varieties as our floral experimentalists can establish for the next century. A white blush *Rose*, christened after *Imogen*—a gorgeous crimson *Pelargonium* called *Cleopatra*—a delicate new *Pansy* published as *Ophelia*, would be ten times fitter than the absurd habit of clapping some male notoriety's unmusical cognomen upon a fair and graceful blossom. *Roses* especially have been most outrageously treated in this way; and, though "by any name they smell as sweet," yet who would

not sooner set in his button-hole a *Juliet* or a *Perdita* than be told that the lovely creation which delights sense and mind is a "Giant of Battle" or a "Mrs. John Jones"? We want, in fact, a second *Linnaeus*, who shall unite science and fancy in the honourable task of rechristening beautiful new flowers. *Olontoglossum coprosma* and *Skimmia japonica* are horrible combinations, the like of which should be confined to outlandish foreigners; but for English-reared blooms English titles of the old sort are surely best, and, failing the help of him who gave us the delightful names of old, let us by all means go to Shakespeare, Chancer, and Tennyson. There may be fancy displayed, as well as melodious words chosen. *Elaine*, the *Lily-maid of Astolat*, ought to have the next new *Lily*; *Rosalind* the next *Rose*, or, if it were a specimen with blood-coloured specks on pale petals, then *Lady Macbeth*. The choice would be endless, and if a careless or injudicious cultivator should give the red hue of *Lancaster's Rose* to some offspring of the House of York, better ereu that than "Mrs. John Jones"!—*Telegraph*.

## THE BEST PHLOXES.

THE following brief descriptive notes refer to a selection of the best varieties in the rather extensive collection of Phloxes grown for trial at Chiswick in 1872. The plants were all young and vigorous, and therefore fairly comparable as to the results of the season's growth. The advance as to quality observable in these useful hardy summer flowers since the last trial took place at Chiswick, was very striking. Those varieties to which the Floral Committee awarded marks of merit (indicated by asterisks, \*\*\* being the highest award), were conspicuous either for their bright and pure colours, the fine smooth even outline of the individual blossoms (pips), or the bold panicles in which the flowers were massed, all these desirable qualities being in most instances associated.

\*\*\*A. F. BARRON (Downie & Co.).—Rose, with bold deep crimson eye; extra fine. One of the best.

\*\*\*BORÉE (Downie & Co.).—Rich shaded rosy amaranth; fine.

\*\*\*CHANZY (Downie & Co.).—Large, rosy purple, with deep crimson eye.

\*\*\*DELIVERANCE (Downie & Co.).—Pale rose, with purple rose eye. In the way of Madame Moisset; but the eye is smaller than in that variety.

\*\*\*EDITH (Parker).—White, with rosy purple eye; dwarf habit.

\*\*\*LOTHAIR (Downie & Co.).—Bright deep salmon rose, with bold rosy crimson eye; very fine. One of the best.

\*\*\*MADAME LA COMTESSE DE TURENNE (Parker).—White with pale purple eye; a bold grand flower of very fine quality. One of the best in the collection, and the best of its class.

\*\*\*MADAME DOMAGE (Downie & Co.).—Large, white, with very large deep rosy crimson shaded eye.

\*\*\*MADAME GUILLOTTEAUX (Downie & Co.).—Deep crimson purple, with crimson eye.

\*\*\*MADAME MOISSET (Downie & Co.).—Pale rose, with deep rosy crimson eye; fine.

\*\*\*MEXORUM (Downie & Co.).—Lilac, with large white eye; very distinct and pretty.

\*\*\*MONS. CONRAD (Downie & Co.).—Deep bright salmon rose; fine.

\*\*\*MONS. DOMAGE (Downie & Co.).—White, with clouded purple eye.

\*\*\*MONS. MALEI (Downie & Co.).—Lilac, paler at the centre; very dwarf habit, and producing large compact panicles of flowers; a very fine variety. One of the best.

\*\*\*MONS. RAFALIN (Downie & Co.).—Bright salmon, with dark eye; small flowers in compact panicles.

\*\*\*MONS. TAILLARD (Veitch).—Bright salmon-rose, with rich purple eye.

\*\*\*MONS. THIBAUT (F. & A. Smith).—White, with bold purple-crimson eye; a remarkably smooth and effective flower; extra fine. One of the best.

\*\*\*QUEEN OF WHITES (Downie & Co.).—Large, finely shaped, pure white, in grand panicles.

\*\*\*AMABILIS (Parker).—Light salmon, with deep rosy crimson eye; good habit and free.

\*\*\*DUC DE PLAISANCE (Downie & Co.).—Large-flowered, rosy crimson.

\*\*\*FOUDROYANT (Downie & Co.).—Bright deep crimson-purple.

\*\*\*MADAME BARILLET (Downie & Co.).—Blush white, with large bright-rose eye; small flowers in compact panicles.

\*\*\*MR. HUGH LOW (Veitch).—Deep purple-crimson, with crimson eye.

\*\*\*MRS. DOMBRAIN (Downie & Co.).—White, with deep crimson eye; small flowers in compact panicles.

\*\*\*ROI DES ROSES (Veitch).—Rosy salmon, with dark eye.

\*\*\*VENUS (Downie & Co.).—White, with rosy crimson eye, changing to purple.

\*\*\*MADAME CAEN (Downie & Co.).—Whitish, with large shaded deep rose centre.

A large number of other varieties were grown; but as they were passed over by the committee as inferior to the sorts named above, it is unnecessary to describe them.—*T. Moore, in "Royal Horticultural Society's Proceedings."*

## NOTES AND QUESTIONS ON THE FLOWER GARDEN.

**Thyme for Walls.**—I was pleased to find the other day quite a plantation of the common Thyme on the top of a brick garden wall, and, as I observe THE GARDEN has said a good deal on plants for walls, I thought it might be worth while informing you of the fact.—B.

**Roses for the Walls of Churches.**—The walls of Chiselmist Church are now so beautifully embellished with Banksian and other Roses, that they remind one of the loveliness that might be added to every church by similar means. Generally the walls of churches are bare, and their aspect anything but cheering.—B., *B. sub.*

## THE FRUIT GARDEN.

## PREPARING STRAWBERRIES FOR FORCING.

No time should be lost in the rooting and the growth of the plants for next year; for as is the strength and maturity of the crowns this autumn, so, with fair treatment, will be the crop of fruit next spring. It is possible to wreck a good prospect by bad management in the forcing. It is impossible to force fine fruit out of weak crowns; or, to put it more correctly, the forcing of Strawberries is a development, not a creation. The embryo fruit that is to be finished and eaten in the spring of 1874 must be formed this autumn. Nothing can be brought out of the plants then that is not laid up in them within the next three months; hence the importance of laying in vigour, storing up strength, without a moment's loss of time. Those nut-brown crowns that we desire to see by-and-by are but the outer coats of bold trusses of blossoms and mellow masses of luscious fruit. They are formed now; the heat and moisture of our forcing brings them to maturity. But it cannot be too often repeated that no amount of heat, moisture, food, or even light can make Strawberries in the early spring that had no existence the previous autumn. In growing strong plants, and maturing that growth now, we are simply preparing fruit for future eating. Our sole business is to make fat, plump, ripe crowns; that accomplished, fruit in plenty succeeds as a matter of course. In the pursuit of this object it is needful to select our plants with care. Among several varieties of Strawberries, notably Keens' Seedling, a greater or lesser number of useless drones—that is, barren plants—find their way. Naturally these plants, having done nothing else, grow; they throw out a prodigious number of strong runners—from twenty to thirty to a plant is no uncommon progeny; and they root speedily and make rapid progress. Hence it comes to pass that the Strawberry layer, unless carefully instructed, is almost sure to lay these barren plants. Woe betide those who trust to those next spring; they will prove nearly all barren or worthless. Degenerate plants—spurious, barren, or comparatively unfruitful—are apt to creep in among other varieties, though seldom in such numbers as among Keens'; and if they are laid, mortification and disappointment are the issue. To guard against such failures, it is good practice either to pull up and destroy every doubtful plant while the Strawberries are in fruit, or to layer the plants for forcing at that time. Then, of course, only the runners of the best and most fruitful varieties would be chosen; and there are great differences among Strawberry plants of the self-same sorts grown side by side. By selecting only and always the best, doubtless our strains would be improved, while we should escape that greatest of disappointments, the finding nothing but leaves when we come to look for fruit next March or April. I know there are some cultivators who think all such care in the selection of plants needless; they contend that the barren plants of one year may be fruitful the next. Sometimes it may be—I believe is so—but more frequently it is otherwise, and we ought to run no risks of failure that foresight and care can avoid. Others have panaceas against barrenness, such as rejecting the first runner and choosing the second, and many other fantastical means. They contend that their plants are thus all, and always, fruitful. I cannot say that I have ever found any difference between first, second, or third runners; but occasionally useless runners have enormously large leaves and very small crowns. I have rejected such in favour of those in which the conditions were comparatively reversed; for our object is crowns, not leaves, or, at least, only the latter as subsidiary to the former. The best and quickest mode of proceeding is to layer the runners in pots at first. Some use small pots to root them in, others shift into the next size as soon as rooted, and finally into the fruiting pots. Others layer them in 6-inch pots at once. Either way answers well. The latter, however, is apt to exhaust the soil before the roots are able to feed freely upon its richness. As to the soil to use, there is none better for Strawberry plants than a somewhat strong calcareous turfy loam, enriched and ameliorated by a sprinkling of bone dust, lime rubbish, and soot. Place also a pinch of soot over a few inches of loam that overlay the three or four crocks. This balks the worms and snails,

and the roots revel in and like it. It is impossible, if the soil is fairly dry, to pot Strawberry plants too tightly by the use of the hands only. Firm potting is one great secret of a strong robust growth. Rich composts send the plants leafwards rather than fruitwards. It is easy to feed the plants in the spring with manure-water by double potting, or standing the pots on a base of dung, turfy loam, &c.

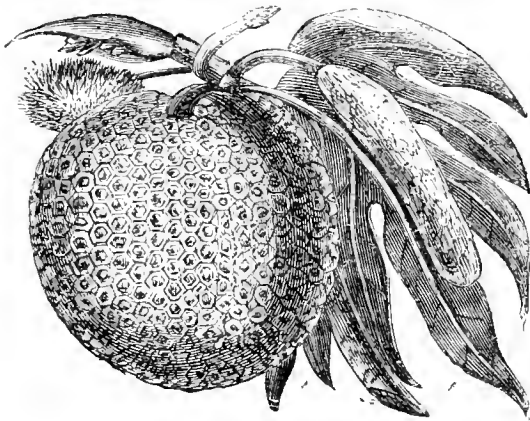

A great error in Strawberry forcing is that of over potting, and I believe plants in large 18's or small 32's will produce crops superior in every respect to plants grown in larger pots. Nearly forty years ago I saw a grand crop of Strawberries at Castle Ashby, near Northampton, in 60-sized pots, standing on a thick turf; each plant had a single flower-stem, and four to six fruits, thinned so as to ripen and be gathered in the bunch. Where monster fruit are required, to thin to three or four fruits is the rule.

A.

### THE BREAD-FRUIT.

(ARTOCARPUS INCISA.)

Of this celebrated tree there are two species, the Bread-fruit, properly so called (*Artocarpus incisa*) and the Jaca or Jack-fruit (*A. integrifolia*). The first-named is the Bread-fruit so well known in connection with the history of the South Sea Islanders, the mutiny of the *Bounty*, and the romantic colonisation of Pitcairn's Island, which was the result of that memorable and tragic episode. The Jack fruit is chiefly confined to the S.E.

The Bread-Fruit.

district of the continent of Asia and the islands of the E. Indian Archipelago. Its fruit is inferior to that of the Bread-fruit tree proper, being neither so palatable nor so nutritious. The Bread-fruit of the South Sea Islands is a handsome tree, about 40 feet high, and the trunk, when full grown, is from a foot to 15 inches in diameter. The branches commence at about 10 or 12 feet from the ground, and stand out almost horizontally from the stem. The fruit, when ripe, is about 9 inches long, of a roundish-oblong shape and greenish colour, and usually rough on the exterior with hexagonal knobs or prominences. The pulp is white, partly farinaceous and partly fibrous until it is quite ripe, when it becomes yellow and juicy. In the island of Otaheite and other places where the Bread-fruit forms the chief support of the natives, it is gathered before it is quite ripe, and, when roasted until the outside is charred, the pulp acquires a consistency not very unlike that of wheaten bread, and the taste is intermediate between that of bread and roasted Chestnuts. The earliest account of the Bread-fruit is that given by the celebrated navigator Dampier in 1688. He says, "The Bread-fruit grows on a large tree; it hath a spreading head, full of branches, and dark leaves. The fruit grows on the boughs like Apples; it is as big as a penny loaf when Wheat is at 5s. the bushel; it is of a round shape, and hath a thick tough rind. When the fruit is ripe, it is yellow and soft, and the taste is sweet and pleasant. The natives of Guan use it for bread. They gather it when full grown, while it is green and hard; then they bake it in an oven, which scorcheth the rind and maketh it black; but they scrape off the outside black crust, and there remains a tender

thin crust; and the inside is soft, tender, and white, like the crumb of a penny loaf. There is neither seed nor stone in the inside, but all of a pure substance like bread. It must be eaten new, for if it be kept above twenty-four hours, it grows harsh and choky; but it is very pleasant before it is too stale. This fruit lasts in season eight months in the year, during which the natives eat no other sort of bread kind." The Bread-fruit was introduced into our West Indian Islands in a second and more successful expedition under Lieutenant Bligh (the commander of the *Bounty*), but there it has not answered the expectations that induced the Government of the day to persevere in carrying out their well-meant project, as "the Banana or Plantain is more easily and cheaply cultivated, comes into bearing much sooner after being planted, bears more abundantly, and is better relished by the negroes."

### FERMENTING MATERIAL ON VINE BORDERS.

THE well-known effects upon Vines of hot dung when applied as a lining to the border, led to the practice of heating Vine borders by means of hot-water pipes placed underneath the soil; but the latter plan, while by far the most expensive, has not been attended with anything like the success that was anticipated by its advocates; and some good Grape growers have not hesitated to condemn the practice altogether, as being unsafe and dangerous. Be this as it may, however, there can be no doubt that bottom heat or root heat is highly beneficial to Vines; they should have a root temperature at least equal to the mean temperature of the Vinery in which the Vines are growing, for the roots will stand a higher temperature than this with advantage. The only question is how to apply it advantageously. Late Vineries, started after the beginning of March, don't require much assistance in this way; but all Vines, and especially Muscats, started before this date do, more particularly if the roots are outside; and for this purpose there is nothing to match a good bed of litter and leaves. As yet no other plan of applying bottom heat has proved so successful, nor is there any other way, so far as I am aware, of restoring vigour to Vines that have been crippled through feeble root-action, and the best of Grape growers go back to the old plan now and then when all else has failed. Besides, the hot-bed is quick in its action. Vines can be improved in time by enriching the border and applying top dressings, &c.; but the hot dung induces action at once, and will often make a good crop of what would otherwise have been a very indifferent one. The explanation of this is simple. When a Vinery is started in January, let us say, the Vines, obedient to a natural law, burst their buds and come into leaf. The temperature is raised as growth advances, till the leaves and branches have probably a summer heat; while the roots have never had a temperature above 45° or 50°. Under such circumstances the roots always come away weakly from the beginning, the leaves are pale and thin, and as the disparity between the temperature of the roots and branches increases, the symptoms get worse—the leaves flag under a hot sun, the fruit sets badly, and the chances are that at the stoning period shanking or stoneless berries will be the result. Nothing else can be expected. A Pine-Apple plant treated in the same way is affected in exactly the same manner, the cause being nothing else than a want of reciprocal action between the roots and the branches.

Some cover the borders of their early Vineries to keep in the natural heat of the soil only; but this natural heat is not by any means enough when once the Vines begin to grow. The covering must be thick, and composed of materials that will ferment actively and continue to do so for awhile, if good results are expected. A few years ago I was consulted about some Vines about eighty years of age, that were in a bad way, not having borne much, if any, for several years before. They had been started generally about the beginning of February, and, further than a covering of dry leaves, no assistance had been given to the roots in the way of protection. Probably the best plan would have been to replant; but the houses were old and destined to be pulled down before many years, and meanwhile the object was to make the most of things as they were. So at pruning time the Vines were pruned back to the best eye, and in January a lining of litter and leaves was applied to the border which was all outside. When the Vines broke more litter and leaves

were added, and the whole was turned and mixed thoroughly, which set fermentation agoing, raising the temperature of the dung to about 80°; and this practice was continued, keeping the heat of the dung up to 90° or 100°, as the season advanced, till July, when the Grapes were ripe. The first year the crop was light, but fairly finished, and the wood and foliage good—much better than usual. The next year the same practice was followed, with much better results, as the crop was a good one in every respect. Some of the bunches, indeed, were heavy, and figured successfully at more than one large exhibition in June of that year. For six years this practice was continued with equally good success, till the houses in their turn had to come down; the old Vines were not, however, discarded without reluctance. In removing the border afterwards, the effect of the annual covering of leaves and litter was very apparent; the roots of the Vines had come in crowds to the surface, every year taking possession, less or more, of the decayed litter, next to the soil, so that the gardener found it necessary to leave patches of the litter annually where the roots were thickest, which caused the border in the end to look quite uneven. Many similar instances might be given, but I will only give another and a more recent one. One of the Vineries here has been cropped heavily for a number of years. Last year the Vines showed symptoms of distress, inasmuch as the wood was weaker than before. As the crop must come up to time when wanted, I took measures in time by widening the somewhat narrow border outside, and, to facilitate root action, 18 inches of leaves and litter wheeled on to the border in February. The Vines were started about the middle of February, and the leaves, &c., were turned the first week in March, which raised the heat by fermentation to 95°, and this degree has been maintained up till now. The effect upon the Vines has been marvellous; their whole latent vigour seems to have been roused, as is evident from the disposition to grow strongly, even after the crop is swelling, and push out adventitious shoots from the main stem where no visible buds were before, and a thickening up of the young wood to nearly twice the diameter of the last year's wood, as shown by the excisions at pruning time. Now this is not due to the addition to the border, but simply to the stimulating effects of the dung heat, which has not been applied before, the house in question having been started late. Of course it must not be supposed that the soil of the border and about the roots of the Vines is as warm as the lining on the top. Heat descends very slowly, and when the litter and leaves are at 100°, probably the temperature of the border 18 inches below the surface will not be more than 70° or 75°; but a higher temperature than this after the Vines are fairly started will do no harm, and when the berries are swelling and approaching the stoning period, 80° or 85° will be safe. As to the economy of this practice, I would just say that leaves are generally plentiful about a garden, and, mixed with a third of litter, will generate plenty of heat, and the whole comes in as an excellent manure about midsummer for the vegetable quarters.

J. S. W.

#### NOTES AND QUESTIONS ON THE FRUIT GARDEN.

**Time for Pruning.**—The American *Practical Farmer* reports the results of experiments made at the Pennsylvania Experimental Farm, in sawing off limbs of Apple trees at different seasons of the year. It was found that the wounds healed most thoroughly and quickly when the limbs were cut off in June, or during the period of most rapid growth. Hence the inference that pruning should be done early in summer. But before this conclusion is adopted, it must be remembered that rapid healing is not the only desideratum in pruning. If the tree is feeble, and we want to increase its vigour, the pruning should be done early in spring. Amputating large limbs when the tree is growing checks it seriously. Summer pruning should therefore be performed on trees of thrifty growth only.

**Fruit Trees as Fences.**—One of the latest ideas about fencing is to plant trees for posts, and when they are strong enough, to string wires from one to another. The kind of tree is unimportant, but, of course, fruit trees will be more profitable than other sorts of trees. In places in which they would be much exposed, other kinds of trees might be planted for shelter.

**Apple Blossoms.**—There is a peculiarity in the flowers of Apple trees which I have not heard mentioned by observers or noticed in books. Each flower bud almost invariably produces a cluster of six flowers, one of which is a robust flower in the centre of the cluster, and this flower is nearly pistillate; in a circle around this are the five others which are more feeble and of a lighter shade of colour than the centre one; these five are nearly staminate, and drop off as the centre one matures into an Apple.—*New York Tribune*.

#### THE GARDENS AND PALACE OF SANS SOUCI AT POTSDAM.

The gardens and palace of Sans Souci have been called the Prussian Versailles, and, in some respects, they merit that title; for the decidedly French tastes of Frederick the Great, the patron of Voltaire, imparted to them a decidedly Versailles-like aspect. Sans Souci is, however, far inferior to its model, both in the size and magnificence of the palace, and the extent and profuse decoration of the gardens. Nevertheless, it possesses a certain grandeur of character, though on a comparatively miniature scale, which at once stamps it with the aspect of a truly regal seat, as will be seen by our engraving. With very little additional grasp of design, and a moderate extension of its limits southward, it might, indeed, have surpassed Versailles itself in one especial feature. That noble garden suffers greatly from the want of natural water *in situ*, while at Sans Souci, by enclosing a further portion of ground southward, as far as the banks of the Havel, which a hundred years ago would not have been very costly, the gardens of Potsdam would have commanded a picturesque and invaluable addition, which no amount of the most lavish expenditure could ever confer upon Versailles. The Havel, formed of branches both of the Elbe and the Oder, widens into lake-like reaches in the neighbourhood of Potsdam, and is studded with islands, and varied by far-jutting promontories, which render it extremely well fitted for the production of grand horticultural effects; so much so, that it appears really astonishing that neither the king's enthusiasm for gardens and gardening, nor the skill of the horticulturists he employed, should have entertained such a view of the capacities of the site of Sans Souci. Perhaps, however, the termination of the gardens a few thousand yards or so short of the Havel, is owing to the fact that this had been the boundary marked out by the Electors of Brandenburg, the predecessors of the great king, who made the old palace and garden of Potsdam their summer residence, a circumstance which, perhaps, induced Frederick to respect the limits they had established in that direction, whatever alteration in the enrichment of the palace in the French style he might cause to be adopted when he selected Sans Souci as his favourite summer retreat.

The transition from the dingy ugliness of Berlin, and the depressing sandy plains by which it is surrounded, to the green bosquets and pleasant fountains of Potsdam, is always agreeable; and, as the transit may be accomplished in forty-five minutes, five or six times a day, it is naturally a very favourite resort of the Berliners during the summer months, though they have the Thier-garten and the pretty grounds of Charlottenburg so much nearer at hand. The gardens of Sans Souci owe their splendour, and also their present name, to Frederick the Great, whose French taste and love of art and literature were joined to a very special love of gardening of all kinds, and to an ambition to emulate the glories of the famous gardens of Paris and Versailles—of the magnificence of the Tuileries, and of the vast artificial waters and fountains which Louis XIV. created out of the woods of his father's unpretending hunting seat. The gardens of Sans Souci are situated close to Potsdam, a town of 35,000 inhabitants, and which contains four other palaces with gardens on a smaller scale. The planting and sculptural decorations of the gardens of Sans Souci are, as stated, in the style of those of Versailles, as will be seen in our engraving, but having a certain North German primness which is entirely their own. There are numerous alleys, with low hedges scrupulously clipped to rule and square, both at sides and top, and other avenues, with trees of very lofty dimensions, topped by clean martinet croppers to the very summit; but there are also certain parts of the grounds in which the trees and their foliage are allowed to assume their natural form of growth, which redeems the aspect of the general scene from its formality and stiffness. A broad, open walk, of fine effect, runs through the whole length of the gardens, only interrupted by a noble basin, from which issues the grand jet said to rise to a height of 130 feet. The basin is surrounded by statuary, vases, and stately marble seats, and forms a fine and conspicuous feature in the gardens. It is from this point that our illustration has been taken. The Palace of Sans Souci—constantly the summer residence of Frederic III. (whenever his summer abode was not

VIEW IN THE GARDENS OF SANS SOUÏ.

in a tent in the territories of his enemies)—is approached by a flight of steps, interrupted by broad flats in the form of terraces, which produce an imposing and stately effect. The palace, however, is not remarkable, either for its architecture or its extent, being low, and but slightly altered by Frederic from its former condition; however, it is full of interesting memorials. Amongst other things is the now celebrated clock, which is regarded with almost superstitious veneration. The king had been accustomed to wind it up himself, but in the last days of his illness had been unable to do so, and it stopped at the precise moment of his death. The hands still point to the hour, having been scrupulously left untouched. Other matters of the kind possess a certain degree of interest, but having nothing to do with our main object—horticulture—must be passed over. The following anecdote, however, is somewhat to our purpose: The Prince de Ligne, a brilliant soldier, a wit, and an enthusiastic lover of gardening, being on a visit at Sans Souci, the king began to pour out to him his troubles as a gardener. Frederic complained that, despite all the care and skill of his gardeners, and his own personal attention into the bargain, neither his Melons nor his Grapes were fit for the table of a Parisian *bourgeois*, on account of the ungrateful sandy soil, through which all attempted enrichments percolated and disappeared. "Sad, indeed," replied the prince, "but at all events your majesty's *Tourneforts* thrive to admiration." Frederic took the utmost interest in his gardens, even to handling the spade himself on occasion, evidently enjoying the exercise. His Melons and Oranges were, however, the objects of his greatest care, not even excepting the Vineries; and he understood all the best principles of the practical gardening of that day, as well as his professional subordinates. He much wished to enlarge his gardens at the back of the palace, where his Melonries and Orangeries, as well as his kitchen gardens, were chiefly situated, and, for this purpose, gave orders for a certain mill to be purchased with its surrounding ground of a few acres. But the proprietor, a sturdy miller, declined to sell; and, it is pleasing to find that even in those days of almost pure despotism, there were private rights which could not be invaded with impunity. The king resorted to law, and after a protracted suit the would-be purchaser being willing to give twice its value for the property—the judges pronounced in favour of the miller, and his Majesty submitted with a good grace—indeed, with a magnificent grace, making the miller a handsome present in honour of his courageous defence in a contest with royalty. A descendant of the independent miller getting into difficulties, offered at last to sell his encumbered property to the government, but the reigning monarch, instead of taking advantage of his position, relieved him from all his difficulties and reinstated him in full possession of the mill, in honour of his sturdy ancestor; and the mill is now considered a national monument, being shown to all visitors, who ought to know something of its story.

In view of the gardens, beyond the extremity of the great avenue, and nearly two miles from Potsdam, is the Neue Palais, built by Frederick the Great after the Seven Years' War, in order to prove that his finances had in no way suffered from the protracted contest. The works were carried on unremittingly during six years, from 1763 to 1769, and even then the interior was far from being completed, and the general result, as an architectural work, very unsatisfactory. The gardens at Sans Souci emulate Versailles in water-works, which play twice a week, and are furnished with an abundance of temples, porches, pagodas, and other architectural devices, not always in the best taste; but in one of them, called "the antique temple," is a statue, by Rauch, of the beautiful and unfortunate Queen of Prussia, which is alone worth a pilgrimage to Potsdam to see and to admire. Within the gardens of Sans Souci, is a villa in exact imitation of a Pompeian residence, and which, even to the baths, is intended for use as well as ornament. It was built by the late King when Crown Prince, whose love of art will be well remembered. In the suburbs of Potsdam are the summer residence of Prince Charles, on the Yung-Fern See, and the small palace of William I., known as Babelsberge, which is situated on a broad reach of the Havel.

NOEL HUMPHREYS.

## THE ARBORETUM.

### VARIETIES OF THE COMMON YEW (*TAXUS BACCATA*).

As many of our favourite Evergreens, hitherto reputed hardy, have been seriously damaged or destroyed by the last winter's frost, we turn with increased interest to those which remain to us uninjured. Bays, Evergreen Oaks, Arbutus, Euonymus, Laurustinus, Common Laurels, Cypress, and in some cases Portugal Laurels, are killed. Aucubias, Deodaras, and some other South American and Indian beauties have in many places complexions as brown as ground Rhubarb; Phillyreas and more hardy Evergreens are stripped of their leaves. But our native plant, the common Yew, is safe; none of the varieties have a leaf injured in this valley of the Lea, where the thermometer on Christmas Day was five degrees below zero.

The common Yew is, no doubt, well known to every observer, but perhaps the numerous and beautiful forms which have descended from it are as yet strangers to the many. It is these varieties which I would now attempt to describe. They are many in number, beautiful in appearance, and vary greatly among themselves. Neat, graceful, elegant, picturesque, sombre-massive, grand, are terms which may be appropriately used to one or other of them.

It is my present intention to look at them from one point of view only, and that a popular one—their value as ornamental trees in garden scenery—and so regarded, they seem to fall naturally into four groups, viz. :—

Group 1.—Varieties of a spreading habit, of which the common Yew is the type.

Group 2.—Varieties of pyramidal or columnar habit, of which the Irish Yew is the type.

Group 3.—Varieties of weeping habit.

Group 4.—Varieties with variegated foliage.

#### GROUP I.—VARIETIES OF SPREADING HABIT.

*T. BACCATA*, common Yew.

*T. B. FRUCTU-LUTEO*, the yellow-berried Yew. This is one of the most elegant; the pulp surrounding the seed is of a dull yellow colour instead of red, as in the ordinary kind. The growth is vigorous; the leaves are of a very pleasing green medium tint.

*T. B. NIGRA*. This is a striking plant of bold and rather upright growth; the leaves are of a bluish or blackish-green. It flowers abundantly, and is very effective in the landscape, forming a somewhat sombre, but grand and massive tree.

*T. B. PROCUMBENS*, forms a huge spreading bush; leaves bright green, the plant, looked at as a whole, having a reddish appearance.

#### GROUP II.—VARIETIES OF PYRAMIDAL, OR COLUMNAR HABIT.

*T. B. FASTIGIATA*, the Irish, or Florence Court Yew, is a plant of rigid growth, columnar in form; leaves dark green. This plant is too familiar to require an extended notice, although very useful in formal gardening. Seeds of this variety produce for the most part the common Yew, but some vary in form and tint.

*T. B. CHESHUNTENSIS* is a very graceful variety, of pyramidal growth, the leaves small and closely set on the branches; the colour is of a bright glossy green. It appears to stand midway between the common and Irish Yew, but is less formal than the latter and grows twice as fast. This variety was raised by me some years ago, from seeds of the Irish Yew.

*T. B. PYRAMIDALIS*. This variety resembles *cheshuntensis* in outward form; the leaves are, however, broader and shorter, and the bark of the young shoots reddish.

*T. B. NIDPATHENSIS*, the Nidpath Yew, resembles *cheshuntensis* in the leaf, branch, and colour of the foliage, but is of stiffer growth, being columnar rather than pyramidal in habit, with a disposition to spread at the top.

*T. B. STRICTA* is similar to the preceding, but with smaller and paler green leaves; it is almost as erect as the Irish Yew, and forms a compact dense tree. This is a seedling from the Irish Yew, raised from the same batch as *cheshuntensis*.

*T. B. NANA* is a neat plant of dwarf habit, and compact upright growth; the leaves of a dark and more glossy green than the common Yew. It appears equally suitable for a single tree on the lawn, for planting in masses, for the shrubbery, or for a dwarf hedge in a geometrical garden. This also is one of my seedlings raised from the Irish Yew.

*T. B. ERECTA* is similar to the preceding, but of larger growth, although with smaller leaves.

*T. B. ERECTA CROWDERI*, the variety recently brought under notice by Mr. Crowder, of Horncastle, is of compact pyramidal growth, and approaches more nearly to erecta than to any other, but has smaller branches, and will probably not grow to so large a size. It appears of more regular growth than erecta, and may perhaps be considered an improved variety of it.

*T. B. ERICOIDES (EMPERIFOLIA)* is an interesting and neat little

plant of dwarf growth, closely set with branches; the leaves are small, the bark reddish.

GROUP III.—VARIETIES OF WEEPING HABIT.

T. B. DOVASTONII is a weeping variety, somewhat picturesque, the branches drooping horizontally to some distance from the main stem, and drooping at their points. The foliage is ample, of a dull dark green.

T. B. JACKSONII is a distinct and elegant weeping variety, with small light green leaves somewhat curled.

T. B. REICHAIIA is a handsome variety, with leaves of a pale dull green. The habit is diffuse, rather drooping, the leaves curled in the way of *Picea nobilis*.

GROUP IV.—VARIETIES WITH VARIEGATED FOLIAGE.

T. B. VARIEGATA, the Golden Yew, is a well known plant of great beauty, well suited for planting in masses, and relieving the monotony of large surfaces of green. The gardens at Elvaston Castle derived some of their celebrity from the artistic working up of quantities of this beautiful tree in contrast with the darker shades of green. I have heard it said, on good authority, that the Golden Yew is a male plant, but as I have scented it, I strongly suspect that there are two or more varieties of too close an external resemblance to be distinguished. This supposition is strengthened by the fact that the offspring from seed retain the variegation of the parent, though differing slightly among themselves.

T. B. ELEGANTISSIMA is paler in colour, and of more erect and uniform growth than the last-mentioned. Both these varieties, if grown entirely in the shade, quickly become green, but regain their golden appearance on re-exposure to the sun. They form handsome formal plants when worked standard high on the Irish or common Yew.

T. B. "SILVER VARIEGATED" is a seedling from the Golden Yew, but which I never thought sufficiently distinct or attractive to merit a name.

T. B. FASCICULATA VARIEGATA, the variegated Irish Yew, is a sport from the Irish Yew, with occasional silver leaves. The plant is of slow growth, and still scarce, but it is hardly striking enough to become a general favourite.—*William Paul (Wallham Cross)*, in "Proceedings of Royal Horticultural Society."

**The Black Walnut.**—Within the past half-dozen years this tree has attracted considerable attention, owing to the high price of black Walnut lumber. A man who expects to sell timber of his own raising would need to commence planting quite early in life, for the trees are not available for this purpose until they reach a large size. Still, as the world goes, men usually try to lay up money for their children, and a forest of this tree would be as safe an investment as bank stock, and not half so likely to be tampered with by unscrupulous officials. As the black Walnut is excellent timber for other purposes besides sawing into boards to be used for furniture, a man could plant a forest, cut out and use the small trees from time to time as wanted for fuel, posts, and rails, and leave the remainder to grow into large trees. The tree is very hardy, and grows rapidly on soils rich in vegetable matter.—*Tribune*.

**Oak and Ash.**—The old tradition is given in this month's part of the *Book of Phrase and Fable* (Cassell & Co.) as follows: "If the Oak gets into leaf before the Ash we may expect a fine and productive year; if the Ash precedes the Oak in foliage, we may anticipate a cold summer and unproductive autumn. In the years 1816, 1817, 1821, 1823, 1828, 1829, 1830, 1838, 1840, 1845, 1850, and 1859 the Ash was in leaf a full month before the Oak, and the autumns were unfavourable. In 1831, 1833, 1839, 1853, 1860, the two species of trees came into leaf about the same time, and the years were not remarkable either for plenty or the reverse; whereas in 1818, 1819, 1820, 1822, 1824, 1825, 1826, 1827, 1833, 1834, 1835, 1836, 1837, 1842, 1846, 1854, 1868, and 1869 the Oak displayed its foliage several weeks before the Ash, and the summers of those years were dry and warm, and the harvests abundant." In the latter category, there are five famous vintage years. This year the two kinds of trees budded almost simultaneously.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

**Rhododendron Falconeri.**—There is a fine specimen of this now in flower at Cobham Park, the seat of Mr. Coombe. The leaves are 15 inches long, and it bears five heads of its huge cream-coloured blossoms.—I. F. M.

**The Great Guelder Rose (Viburnum macrocephalum).**—This noble shrub may now be seen in perfection at the Botanic Gardens, Glasnevin, literally covered with large trusses of its snow-white flowers. It is planted against the wall of one of the greenhouses, outside, and never receives any protection. It is a most useful plant where cut flowers are in demand, and should be more extensively cultivated, if only for that purpose alone.—*Gardener's Record*.

THE PROPAGATOR.

THE FERTILISATION OF THE YUCCA.

In his fifth annual report on the "Noxious, Beneficial, and other Insects of the State of Missouri," Mr. C. V. Riley, the State Entomologist, remarks that many plants are pollinised by the wind, but by far the greater number are rendered fruitful by the action of insects. Mr. Riley uses the *Asclepias* as a familiar example of a plant which may have several pollinising agents among insects. In plants of this genus, each of the flowers which form the umbel is so constructed that the pollen masses can only come in contact with the stigma by artificial means. These pollen masses hang by a bent stalk (see Fig. 1, which represents a pistil of *Asclepias* bearing pollen masses), attached to a flattened, ovoid, brown organ, having a cleft which catches the claws or tarsal hairs, or the fine hairs surrounding the trophi (instrumenta cibaria), of insects wandering over the umbel. The *Yuccas*, so far as Mr. Riley has been able to ascertain, in the United States, depends on the attentions of a little Tineid which he has named *Pronuba Yuccasella*—at least he says that such is the case with capsule-bearing species, those with dry dehiscent pods. His own observations have been made upon a filamentose species growing near St. Louis, assumed to be *Y. puberula* or *glauca*. Mr. Riley's attention was first drawn by Dr. Engelmann to the fact that plants of the genus *Yucca* must be fertilised by the agency of an insect. It appears that the sagittate anthers open a little earlier than the perianth and expel the pollen grains, which, being glutinous, remain attached in different sized bundles to the inside of the flower. The stigmatic tube contains nectar, and is connected with the ovarian cells, and the pollen must be introduced into the tube, but cannot be so introduced without artificial aid. Mr. Riley has found several insects frequenting the *Yuccas* about the flowering time, some eating the pollen, others the

Fig. 1.

young fruit, while others again content themselves with sucking the juices from the ripening capsules; but the only insect he has discovered engaged in pollination is the little Tineid, the *Pronuba*, which may henceforth become popularly known as the *Yucca Moth*. The following is the technical description of the *Pronuba Yuccasella* given by Mr. Riley from an examination of 9 males and 15 females (see *b* and *c* in Fig. 2.) Average expanse, female 1 inch; male 0.90 inch. Front wings, above, uniformly silvery-white, the scales loosely set; fringes concolorous; beneath, pale fuscous, with a brassy reflection; paler internally; fringes either concolorous or paler; costa with a brush of dark hairs. Hind wings semi-transparent, pale fuscous both above and below; paler internally; the fringes white and the brush on shoulder dark. Head white; antennae and tongue dingy yellow; maxillary palpi of same colour, with the exception of tentacle, which is darker; labial palpi with scales on second joint dark brown above; eyes black. Thorax white. Legs dingy yellow, more or less covered with pale scales. Abdomen with the terminal joint in female always bare, with the exception of a few short, stiff hairs near tip, and the scales on other joints very loosely attached.

During the daytime the moth may be found resting with folded wings (*b* fig. 2) within the half-closed flowers, but a keen and careful search is necessary, as the insect is hidden and protected by the similarity of the colour of its front wings and that of the flower. In the evening, when the *Yucca* is in full bloom, the male moth may be seen flitting from flower to flower, and by the aid of a ball's-eye the female may be found busily at work. She seems to be thoroughly aware that to secure the continuance of her race she must ensure the fruiting of the plant which furnishes her larvæ with food. "With her maxillary tentacle, so wonderfully modified for the purpose," says Mr. Riley, "she collects the pollen in large pellets, and holds it under the neck and against the front trochanters. In this manner she sometimes carries a mass thrice the size of her

head. Thus laden, she clings to the top of the pistil, bends her head, thrusts her proboscis into the stigmatic nectary, and brings the pollen mass right over its mouth. In this position she works with a vigour that would indicate combined pleasure and purpose, moving her head and body from side to side, and apparently making every effort to force the pollen into the tube." Thus far the habits of the little insect have been frequently observed, but for want of time and opportunity Mr. Riley has not yet been enabled to witness the act of ovipositing. He feels satisfied, however, that the eggs are not deposited on the outside of the fruit; but are either thrust into it from the side or from the stigmatic opening, following very likely the course of the pollen tubes. Up to the present he has not yet been able to discover the egg *in situ*, which is explained by the fact that the egg when examined in the abdomen of the female is found to be long, narrow, soft, flexible, and of the exact colour of the flesh of the young fruit. The ovipositor is so fine and extensible that it may be thrust into the most minute opening. A day after the flowers have withered, the larvæ, from one to half a dozen, may be found in the nascent seed, but so similar in colour that they would be difficult to detect, were it not for their comparatively large and dark jaws. The larva remains of a white colour till after the last moult, when it puts on the caraneous tints usual amongst fruit-boring moth larvæ. The following is the technical description of the larva, founded on the inspection of many specimens:—Average length, 0.55 inches. Broadest on thoracic joints, thence gradually decreasing to extremity, which is quite small (fig. 2, a). Colour caraneous, with a paler greenish tint below. No piliferous spots, but a few very minute and short stiff hairs springing from the ordinary positions of such spots. A transverse dorsal wrinkle on each of the principal joints, more or less distinctly divided in two by a medio-

Fig. 2.

dorsal depression, which is sometimes slightly bluish. Joints deeply incised and with a lateral, substigmatal, longitudinal wrinkle (*d*). Thoracic legs stout, but short, with three joints and a claw. No prolegs. Stigmata (nine pair) forming a small rufous circle on anterior portion of joints, I and 4-11. Head (*c, f, h, i, j, k*) partially retractile, copal-coloured; labrum slightly pilose; mandibles stout, rounded, and with four acute teeth, each diminishing in size from without; maxilla with the inner lobe rounded and furnished with (usually two) short fleshy hairs, the palpi four-jointed, the terminal joint with bristles; labium prominent, with the spineret conspicuous and the palpi two-jointed—the first joint long, with a fleshy hair at tip, the second small, spherical, and also terminating in a fleshy hair; antennæ two-jointed, the terminal joint with a bristle; ocelli pale, around a dark crescent. Cervical shield flattened and not well defined. White when young. Mostly curved in the fruit.

Each fruit-pod of the *Yucca* contains upwards of two hundred seeds, disposed in six rows, and, as it is seldom that two larvæ are found in the same row, and very rare that each consumes the inside of more than twenty seeds, it will be understood that abundance of seed is left to perpetuate the plant, especially as the *Pronuba* deposits as a rule only two eggs in each pod. It is possible that the moth may in some instances introduce the pollen without depositing eggs, but Mr. Riley says that, after examining many hundreds of capsules obtained from different parts, not more than 5 per cent. were uninfested. Sometimes every pod on a plant had its tenants, whilst at others half the pods on a panicle would be free from them. Oviposition, he thinks, follows naturally and immediately upon fertilisation, unless the moth happens to be disturbed.

When the larva is full-grown it bores a hole through the capsule, drops by a thread to the ground and burrows a few inches beneath the surface, where it makes an oval cocoon of earth lined with silk, and hibernates in that state, rapidly completing its transformations about the time when the *Yuccas* begin to bloom, its chrysalis existence being very brief.

Such is the life-history of what must be acknowledged to be one of the most interesting of all insects—an insect only recently noticed,

and yet whose operations, taken in connection with certain theories might very well form the subject matter of a whole volume.

Mr. Riley expresses the belief that wherever the *Yucca* has seeded the *Pronuba* has been present, and he thinks it not impossible that the larva has been carried with the seed. It is quite certain that it may be transported long distances in the cocoon. Of seventy plants in a garden at Kansas City not one has ever produced seed, nor have others at Salem and Cambridge, Mass. In cases where the plants have yielded seeds Mr. Riley contends that the *Pronuba* may have been present without being noticed, a proposition not by any means difficult of acceptance, seeing that the insect has so long been unknown to botanists and entomologists. It would be interesting to learn whether there is another insect provided by nature to assist in fertilising the *Yucca* when removed from its native habitat, or whether, as may be the case in some very exceptional instance, the plant is enabled by some spontaneous alteration of structure to fertilise itself.

## THE KITCHEN GARDEN.

### THE POTATO DISEASE.

BY WILLIAM CARRUTHERS, F.R.S.

THERE is reason to believe that the Potato disease has been known for ages in the western countries of South America; but its first ascertained appearance was just thirty years ago, when it seriously injured the crops of the United States and Canada. It reappeared in the same regions the following year (1844). In the latter half of the month of July, 1845, it was first detected in the Old World, in Belgium, and within two months thereafter its occurrence was recorded in England, Ireland, and Scotland, in France and Germany, Denmark and Russia. Since that time it has never been entirely absent from the Potato crops, although in some years it has been much more destructive than in others. Its extensive prevalence last season, and the serious havoc it committed, threatening a famine in some districts of Ireland, have drawn special attention to it recently, and have induced the President of the Royal Agricultural Society (Earl Cathcart) to encourage the investigation of the nature of the disease by the offer of a prize of £100, in the hope that such investigation will lead to practical suggestions as to a method of palliating, if not of curing, the malady.

With the approval of the Botanical Committee, I have drawn up the following short statement of the present state of knowledge regarding this disease:—

There is no longer any dispute as to its real cause. All the notions which supposed it to be produced by physical agencies, or to be the indication of a defective method of cultivation, or of a deterioration of the plant, have been conclusively set aside. Nor can it be held that the microscopic fungus, which is known to be invariably found in diseased Potatoes is the result of the disease and not its cause, since De Bary has produced the disease by placing the spores of the fungus on the leaves and tubers of healthy Potatoes.

Beginning this narration with De Bary's experiment, we may trace intelligently the history of this baneful parasite, and notice the nature and progress of the injury it produces in the Potato. The seeds, or more properly spores of the fungus, are minute ovoid bodies, so small that the greatest diameter is not more than the eight-hundredth of an inch long.

Spores of *Peronospora infestans*, magnified 300 diameters. One of the spores germinating.

When a spore rests on the under surface of a leaf, and there is sufficient moisture, it pushes out a slender tube, through a ruptured opening in its coat. This tube penetrates the epidermis on the spot where germination takes place or finds its way to one of the innumerable openings or stomates which abound on the lower surface of the leaf, and passing through the opening enters the tissues. The slender tubular root, called the mycelium, rapidly grows, pushing its way everywhere through the substance of the leaf. It branches and rebranches freely; the brown colouring matter contained in it gives the spotted appearance to the leaves, which indicates to the eye the existence of the disease. The mycelium sends out, through the stomates, branches into the air, that give a mouldy aspect to the under surface of the leaf. The ultimate

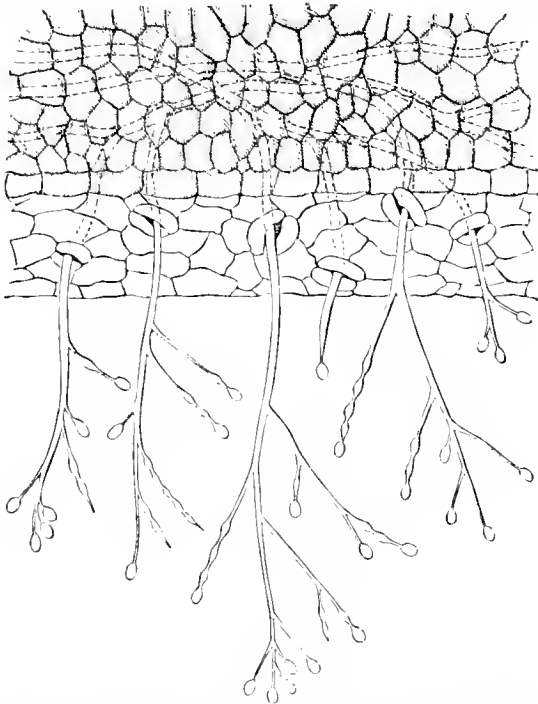

branches of this external growth are somewhat interruptedly swollen, and many of them bear minute oval bodies at their extremities. These are the spores. The mycelium passes down the leaf-stalk into the stem; through this it obtains access to the other leaves as well as to the underground branches, and through them to the Potatoes themselves, which are indeed only enlarged and shortened portions of the underground stem. De Bary placed some spores on the leaves of a healthy Potato on February 4th; the day following the tubes of the mycelium had penetrated the leaves; on the 8th

A spore which has penetrated the epidermis of the stem of a potato, with its mycelium root penetrating the tissues of the stems.

the mould appeared on the under surface, covered with fruit, and on the 9th the whole plant was diseased.

The individual cells which are pierced by the mycelium are destroyed, and the starch-granules contained in the cells are attacked and consumed. Putrefaction soon begins, affecting first the cell-walls and then the starch. Payen has put it beyond doubt that the mycelium consumes the starch, for in his investigations he detected the granules attacked by the mycelium threads, and he made the injury more apparent by using iodine, the action of which in colouring starch granules is well known. By the ordinary processes all the starch can be separated from diseased Potatoes, not only that

Spore-bearing mould, *Peronospora infestans* (magnified 300 diameters). The spore-bearing mould springs from the mycelium, which penetrates the tissues of the leaf, and passes through the stomates on the under surface into the air.

contained in cells yet untouched by the mycelium, but even the granules that remain uninjured by the mycelium or the surrounding putrefaction.

The mycelium does not naturally fruit on the upper surface of the leaf, on the stem, or on the tuber of the Potato, as these parts are either destitute of stomates or but partially

furnished with them, and the mycelium does not send its fruiting branches through continuous epidermal structures; but when any of these parts of the Potato, attacked by the

Spores of *Peronospora infestans*. A. Large spores borne on the mould of *Peronospora infestans*; the contents of the cell divided. B. The small spores (zoospores) escaping from the cell. C. A zoospore with its two cilia. D. A zoospore deprived of cilia, and germinating. (Magnified 300 diameters.)

parasitic fungus, are cut and placed in a moist atmosphere, the fruiting branches speedily appear.

Some of the oval heads which terminate the branches are larger than the others, and contain within them from six to sixteen minute bodies. When water is applied either artificially or naturally, the outer covering bursts and the contents are liberated. Each of the little spores thus set free moves about in the water by the aid of two cilia. In a short time the motion ceases, and if a proper nidus exists the spore germinates.

The minute fungus belongs to the genus *Peronospora*, and

A. Oospore of *Peronospora umbelliferarum*, Casp. B. Small antheridial spore. (Magnified 300 diameters.)

has received the name *Peronospora infestans*, Mont. Another method of reproduction has been noticed in other species of this genus, but it has not yet been detected in the case of the species causing the Potato disease. In the other species the mycelium buried in the tissues of the supporting plant produces two kinds of cells, which have the same relation to each other that the ovule and the pollen grain have in flowering plants. The small cell, representing the pollen grain, when it comes into contact with the larger cell, pushes out a tube which penetrates its outer wall, and on reaching the inner wall induces changes which produce a ripe spore, called an oospore. The oospore is full of small granules, which are liberated, as in the fruit already described, on the application of water, and being furnished with cilia they move about for some time. Although these minute spores abound on and in the soil around the diseased plant, it appears that they never attack healthy plants through their roots, but that they attach themselves to the stems or leaves, penetrating their epidermis or pushing their way through the stomates.

It is to be hoped that the investigations on these fungi which will be undertaken in consequence of the offered prize, may lead to the discovery of these oospores in the *Peronospora* of the Potato. As they are more especially rest-spores, supplying, along with the mycelium, the means of continuing the life of this species in a new season, their discovery and the determination of the part or parts of the plant in which they are produced may supply practical hints as to how to prevent the disease. Under any circumstances, however, and in order to secure the destruction of the parasitic fungus, the diseased plants—whether leaves, stems, or tubers—should be destroyed by fire. Leaving them to decay on the field, or neglecting them in the farmyard and permitting them to get into the manure, is a certain means of maintaining these rest-spores (oospores) and mycelium in a state ready to germinate when the necessary conditions are present.

It is further probable that when we have discovered the oospores in the Potato fungus, which are known to exist in the other species of *Peronospora*, we shall not even then have ascertained the whole life-history of this parasitic fungus; for the recent investigations of De Bary have shown that many of

the microscopic fungi, which have hitherto not only been considered different, but have been classed under different groups, are really stages in the life of the same plant. In the analogous changes in the higher cryptogams, the spores are produced only at the final stage; and among the different forms through which insects pass, only the imago or perfect insect has the power of continuing the species by producing eggs. But in these fungi each stage is spore-bearing. The investigations instituted for the offered prize may, it is to be hoped, disclose some stage in the progress of this parasite's life, where it can be more effectually dealt with than in that stage with which we are at present acquainted.

De Bary has shown by experiment that there is nothing in one Potato plant more than in another to predispose it to the attack of the fungus. It is not weak or unhealthy plants that are attacked, but wherever the spores rest, and, finding the suitable moisture, germinate, there the disease will appear. When once the fungus has got a footing in a crop of Potatoes, its rapid growth, the little time required to develop fruiting branches, and the innumerable number of spores produced, make its progress very rapid. Even when the disease is first noticed by the cultivator, it has taken such a hold of the crop that its cure is, I believe, impossible.

As moisture is so necessary to the development of the spores, every means should be adopted to prevent undue moisture. No soil is exempt; but there is less danger of an attack, and less injury when the disease makes its appearance, in thoroughly drained soils.—*Royal Agricultural Society's Journal*.

### ANGELICA.

If not a British plant (as some suppose), I have seen it growing wild and most luxuriantly in several places, more particularly in Devon; and, about this place (Exmouth), it grows on the high banks, under the cliffs, high up on the shelves and crevices, and on the top of the cliffs most luxuriantly. Owing to its winter and very early season's growth, with its clean, shining foliage of such a beautiful green, and its very early flowering, it really makes a very handsome and interesting plant for the wild garden, nooks of shrubberies, and wood-side walks. With us it commences its growth in autumn, grows on the whole of the winter while the weather keeps open, commences starting its flower-stalks in February, and is in full blossom early in March. It grows from 3 feet to 4 feet 6 inches high, and is really a very interesting sight, with its fine foliage, luxuriant stalks, and large heads of bloom, as seen here in the Primrose-blooming season, and before even the wild Parsley is in bloom. It is more used in confectionery than otherwise; yet many like to have a bed of it for the sake of its appearance, and it grows very well on almost every kind of garden soil—best in those that are moist and deep. It is readily propagated from seed, which should be sown thinly in early autumn (August or September), or in spring; and, as it is a very strong grower, each individual plant should have plenty of room to grow—3 feet apart will not be too much. It should not be allowed to go to seed, unless in the uncommon case of seed being required. It is stated to be a biennial in the gardening books; but we have found it endure from year to year, like any common perennial. It would be more likely to exhaust itself if allowed to flower. The stems, if required for candying, should be cut down in May. In the north of Europe it is used as a vegetable and condiment, but in this country chiefly for confectionery.

JAMES BARNES.

### BORAGE.

"Elo Borago gandia semper ago," which, being interpreted, significth that "I Borage bring alwaies courage;" and, as an old writer pithily remarks, "Pity it were that even a fictitious expellant of the blue devils should become obsolete; better even to be cheated into good spirits than suffered to sink into melancholie for want of a little credulity." Burton, in his "Anatomy of Melancholy," tells us that

Borage and hellebore fill two scenes,  
Sovereign plants to purge the veins  
Of melancholy, and cheer the heart  
Of those black fumes that make it smart.

And our prime old favourite Gerard relates for our edification:

"Those of our time do use the flowers in salads, to exhilarate and make the mind glad; there be also many things made of them, used everywhere for the comfort of the hart, for the driving away of sorrow, and increasing the joie of the mind." Borage is very abundant in the South of Europe, the Levant, and middle Asia. In the neighbourhood of Aleppo it grows so abundantly as to be quite a feature in the landscape; and, what renders it the more noticeable, the flowers there are larger and more intense in colour than with us. It is indigenous to England; its favourite localities are hillsides, and waste places amongst rubbish. If the reader is going to the seaside next autumn and should choose Southsea, let him, one fine afternoon, take the train to Cosham, walk up Portsdown Hill, and he may return home rich with borage for his cider cup and copas. In the days of good Queen Bess, both the leaves and flowers were eaten in salad, and the Borage, with other herbs, was gathered for store, as well as for present use; the dried plant received its meed of praise, for it kept "seeming and savour all the winter long." I am told the young leaves form no bad substitute for Spinach. Some old-fashioned people still use it with honey as a gargle, and in France it is occasionally given for rheumatism and skin-diseases, with what success the writer knoweth not; and a green colour is made from the flowers. The leaves contain a considerable quantity of nitre, which may be proved by holding a bit of the dried plant in a flame. The burning will be accompanied by slight concensation and detonation, hence the cooling properties of the plant. I will hazard an opinion that this is the secret of its curative effects in sore throat, &c. The root is employed in making rouge; the tissues of the plant contain gum, and may be used as a demulcent. Borage you see is, or might be, a very useful "weed," good for something else than cider cup. The bees are particularly fond of it; around its blue blossom they love to congregate, and if they do not find it at home, are apt to wander in search thereof, far and wide—many, alas! never to return; or if they do reach their quarters, die from fatigue on the threshold of their hives. So all ye apiarians cultivate Borage.

With regard to its culture, that is not very difficult: the seeds should be sown nine inches apart, and the sowing may be in spring or August. If the leaves only are to be used, the flower stems should be cut out as soon as they form, the plant will then continue forming leaves successively for three or four months. Leave a plant or two to ripen for seed in your herb garden, and self-sown plants will spring up in abundance. The young plants bear removing, and once introduce the Borage, for a few years you will have little trouble in growing sufficient for your use, and for the bees likewise. At the end of three or four years, however, you will do well to shift your ground and sow fresh seed. Borage makes an excellent manure, and has been sometimes sown in the spring for that purpose, and dug in during autumn.

W. A. R.

### A NEW AND USEFUL HOE.

A GLANCE at our little illustration will show that this is a kind of scuffle hoe, working backwards and forwards. It will be seen that it is diamond shaped, the points or angles to the right and left being most efficient in plucking a weed out of a corner, or when situated close to a plant. It is worked in the same way as one would use a Dutch hoe. It leaves the ground remarkably level, and can be worked with much greater expedition than the common hoe; indeed, with a large one, nine inches wide, a wonderful amount of work can be got over in an hour or two, and with a five-inch hoe of this make 150 yards of 4 feet wide border have been hoed over in less than an hour. One trial of it, in short, is all that is wanted to establish its utility.

A. D.

**Potato Imports.**—So smoothly run the wheels of trade in these latter days, that our markets are but little affected by the fortunes of seasons and crops. A striking instance has occurred, during the last few months, in the matter of Potatoes. I suppose the farmer and the gardener could tell a melancholy story of last year's harvest of this valuable root; but what do the general public, who have eaten Potatoes every day for twelve months just as if nothing had happened, know about the calamity? Practically, the consumer has experienced no particular difference between this year's supply and last; but I have a few figures before me demonstrating a difference. They are the Board of Trade's statistics of imports, and they tell me that in just the four months from the 31st of last December till the 30th of April, instead of importing foreign Potatoes to the value of about £79,000, as we did in those four months last year, or to the value of less than £11,000, as we did in the first four months of

1871, we have actually spent £1,300,000 this year in the purchase of our neighbours' Potatoes. That we should have bought all these vegetables wherever we could get them, to supply our own deficiency, is not wonderful, for the English are accustomed to go to the foreign market with their money in their hands, and to obtain what they want if the article is to be had; but that such an enormous increase of supply should be available on an unforeseen emergency, and that we should have taken them and have eaten them as we have, hardly knowing the difference, is surely remarkable, and a splendid testimony of the elasticity of our commercial system.—*Gentleman's Magazine*.

**Fertilisers in wet and dry Seasons.**—The *Boston Journal of Chemistry* says: One of the most interesting facts which this extraordinary wet season has brought out is that fertilisers applied to soils in dry summers without appreciable effects, are rendered available in those that are wet. The plots upon which our fertilisers have been applied during the past years, when the rainfall has been so deficient, produced wonderfully this season. The fertilising substances have been lying dormant in the soil for the want of water to render them soluble, or to hold them in solution, and this year the conditions have been favourable for promoting the changes, chemical and mechanical, necessary for plant food to be made available. Manures are not lost which do not act promptly, unless they are blown away by winds, or are washed into brooks in sudden and violent showers, which sometimes fall upon the baked earth in summer. If they remain in or upon the soil, favourable seasons, which are sure to come, will force them to give up to plants the food which they contain, and the husbandman receives his returns in abundant crops.

**The Nature of Guano.**—It is a generally received opinion that the deposits of guano are exclusively the excrements of birds. Dr. Habel has investigated this matter microscopically and chemically, and has found that after treating the substance with an acid, the insoluble residue is composed of fossil sponges and other marine animals and plants precisely similar in constitution to such as still exist in those seas. The fact, too, that the anchors of ships in the neighborhood of the guano islands often bring up guano from the bottom of the ocean, is quite in opposition to the prevalent belief. Dr. Habel therefore considers that the deposits of guano must be the result of the accumulation of fossil plants and animals whose organic matter has been transformed into nitrogenous substance, the mineral portion remaining intact.

**Early Peas.**—I sowed some Peas in a sheltered border in November, and made successional sowings every month since that time; but, although I have a fair prospect of good crops, I shall not gather Peas before the 21st or 24th instant—not even from my earliest sowings. I am not, however, alone in my misfortune, for my neighbours complain that their crops are equally late. I have, however, partly overcome the difficulty in the following way:—In the end of January I sowed around the inside of some 6-inch pots some Peas, grew them on slowly in moderately cool pits, and in early April transferred them to a well-sheltered wall border having a S.S.W. aspect, just turning the balls out of the pots, and opening them out so as to have the Peas in a line without breaking the soil any more than I could help. The result was that, on the last day of May, I gathered a dish of good Peas, and the plants have borne a good crop of usable Peas since.—J. A. H., *Twickenham*.

## NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

**Asparagus.**—It is stated by "A." at p. 425, that the late Mr. Ingram showed a bundle of 100 Asparagus heads weighing from 16 to 18 lbs. That is a mistake; I weighed the bundle myself, and its exact weight was 12½ lbs.—CHARLES MAER, *Royal Gardens, Frogmore*.

**Hedges for Exposed Kitchen Gardens.**—If the garden be exposed to cutting winds, hedges must be run through it at proper distances—the distance must be determined by the size of the garden—the hedges should be about 3 feet high, to consist of Beech or Privet, with Sweet Briars alternately, and here and there a China Rose to take off their stiff appearance.

**Hardiness of the Potato.**—The assumption that individual Potato plants vary as to hardness, is not borne out by facts. That constitution has little to do with the matter is proved by the fact that in numerous instances after the frost of the 20th I found that where two stems issued from one root, one was quite frosted and the other unharmed. We must therefore look to some other source for an explanation of the matter, than that which supposes that Potato plants of the same sort differ from one another in constitution.—ALEX. DEAN.

**Arresting Decay in Potatoes.**—Prof. Church, of Cheneester, the eminent agricultural chemist, announces that sulphate of lime appears to exercise a very remarkable influence in arresting the spread of decay in Potatoes affected by the Potato disease. In one experiment the salt was dusted over some tubers, partially decayed from this cause, as they were being stowed away. Some months afterwards the Potatoes were found to have suffered no further injury. A similar trial with powdered lime (carbonate) proved to be much less effective.

## WORK FOR THE WEEK.

### PRIVATE GARDENS.

**Flower Garden.**—Spring blooming plants must now be removed from flower beds, for if that operation is longer delayed the bedding plants will be very backward. Collinsias, though at their best, must nevertheless be removed. Divest Daisies of their blooms, lift them, and transplant them in a cool border. Pansies are yet quite gay, and if plenty of young growth is left in them they will continue to bloom well where they are during the summer, or they may be lifted carefully and transferred to herbaceous borders or the reserve garden. Alyssum Arabis and Aubretias should be removed and transplanted in a cool border; the best of their young shoots should be used for cuttings, which may be inserted in a north-wall border, under handlights or mats for a time. Tulips, Hyacinths, and Crocus roots when lifted should be allowed to become thoroughly dry before they are stored away till the autumn. Remove all flower shoots from the variegated variety of Polemonium caeruleum, Cerastium, golden Feverfew, Stachys lanata, the variegated variety of Spiraea Ulmaria, Garden Cress, and, indeed, from any other kind of plant used chiefly for the beauty of its leaves. In order to prolong, or rather to retard, the blooming period of Antirrhinums, and that of the double-flowering Feverfews, cut over their flower spikes just now, and they will bloom later in the season. Transplant young plants of Canterbury Bells, Wallflowers, and other biennials, and to such as are flowering give a soaking of manure-water. From Peonies and choice Rhododendrons remove all decayed flowers and seed-pods. Thin the shoots of Penstemons and Phloxes, leaving only such as are likely to flower well. Pick off blistered leaves of Roses, and on the first appearance of aphides syringe the plants with tobacco-water if they are not in bloom, but if their blooms are open use clean water only. Budding of roses may be commenced as soon as the eyes are prominent enough. Stake Hollyhocks and Dahlias. Sow annuals for late flowering, and thin out those previously sown. Peg down Puchsias, Heliotropes, Petunias, Verbenas, some of the straggling Polargoniums, Mesembryanthemums, and others, so as to keep the beds in which they are planted neat and orderly.

**Greenhouse Plants.**—Keep plants of Begonia Weltoniensis in a moderately warm house near the glass; they will soon be nicely in bloom. Other herbaceous and fine-leaved sorts are now in good condition. Pot on seedlings and cuttings as they become fit for removals but do not syringe them. Achimenes may be increased by means of young shoots, in the same way as Verbenas. Gloxinias and Gesnera; should not be syringed, as they are exceedingly liable to spot. Re-pot Musas raised in spring from seed, and separate and pot suckers when the old plants show signs of decay. They require good soil, plenty of root-room, abundance of water, and a strong, moist temperature. Of Abutilons have a good stock to mix with other plants—one called *A. niveum aureum marmoratum* has large finely-spotted leaves, and is very ornamental. Plenty of heat and water are necessary to bring them to perfection, after which they should be hardened off for use in the conservatory. Re-pot young plants of *Clanthus Dampieri* that are in want of that attention. Some elevate the soil about the necks of the plants to the same height as that of the rim of the pot; others place a layer of powdered charcoal about their necks; and some feed the plants with water only from saucers placed underneath the pots, so liable is this plant to damp off. Of *Ficus elastica*, young plants should be plunged in bottom heat and kept growing; and, where increase of stock is required, larger plants should have an incision made at the base of a leaf some 2 feet from the end of the shoot, and some Moss and sand, or Peat and sand, should be tied around the wound. This induces the production of young roots; and, after a time, the limb may be entirely separated; thus an entire plant is secured in a short time. Grow on Cockscombs, and other *Celosias*, and keep them near the glass. *Gomphrena globosa* may be treated in the same way; but it should be used very carefully, as it is apt to damp off. Balsams are better grown in a cool airy house than drawn up in heat. Of *Amarantus salicifolius* secure good plants for conservatory decoration, and grow them in a light and airy house. Pinch and keep in good shape *Coleuses*, *Iresines*, &c. *Agrostis pulchella* and *nebulosa* are both pretty plants when mixed with others; therefore, keep up a succession of them in cool pits or frames. Shift regularly *Zinnias*, *Tree Mignonette*, *Asters*, and similar plants, for indoor decoration; and liberally feed *Crysanthemums* and *Liliums*, both of which may be grown in pots, either in frames or out of doors.

**Hardy Fruit Garden.**—Remove blistered and curled leaves from young fruit-trees, and search for grubs, which must be hand-picked and destroyed. Train out the young shoots of Peach, Nectarine, and Apricot trees. Cherries are now beginning to ripen; therefore, some means must be taken to protect them from birds. Give Strawberries a good soaking of manure-water, and have nets or boys to prevent birds from devouring the fruit.

## MARKET GARDENS.

Vegetables are excellent this season, but fruit crops are not so promising as they were some weeks ago. Some Pear and Plum trees have no fruit at all on them, whilst others are bearing a fair crop; Cherries and Apples are moderately good, Gooseberries and Currants are laden with fruit, and of Strawberries there is abundance.

**Asparagus.**—This, though backward at first, has yielded a fair crop. In the case of all plantations under five years old, cutting should be discontinued, but "grass" may be gathered from older ones for some days yet, on account of their being late in coming into bearing. Encourage the growth of young plants by maintaining a loose and clean surface soil, and remove multitudinous spray, preserving only the strongest shoots. On the ridges a crop of French Beans, Lettuces, Beet, Nasturtiums, Coleworts, or other light crops may be grown.

**Beet.**—The first crop has been thinned out to 9 inches apart, and all deficiencies have been made up. The main crop should now be thinned out by means of small hoes, but the plants may be left without being singled out until the next thinning and cleaning. Transplant some on to Asparagus ridges, under moderately open fruit trees, and in any place where ground is to spare; let the rows be a foot or 15 inches apart, and the plants 8 or 9 inches asunder in the rows.

**Cabbage, Cauliflower, &c.**—Any Cabbages still open-hearted should have a piece of matting tied around them. Where they have been planted on Seakale ground, the sooner they are removed the better for the Seakale. Lettuces, Vegetable Marrows, Celery, and French Beans, all form good succession crops to Cabbages, or Potatoes dibbled into the alleys between them frequently do well if the Cabbages be removed before they draw and weaken the haulm. Plant out spring-sown ones as ground and convenience permit. Cauliflowers raised under handlights are now plentiful. Those first planted out are now coming in and look well, as does also the second crop, but the third has been sadly injured by frost. The early Cauliflowers, as well as the Lettuces planted amongst them, should be cleared off the ground as soon as possible, so as to make room for French Beans or Marrows, which should have been planted amongst them some time since, and another crop of Lettuces. Walcheren and Snow's Winter White Broccoli, as well as the Sprouting, should be planted out, the first two sorts in open positions, and the latter under trees. Plant out Brussels Sprouts between rows of early Potatoes, or between every two lines of Cabbages or French Beans. Plant out a few Savoy and Curled Kale, and keep the young plants of all the Cabbage tribe yet in the seed-beds clean and moderately thin, so as to have them strong and well rooted.

**Celery.**—Plant out the early crop in trenches from 5 to 5½ feet apart, and crop the intervening spaces with Cauliflower, Lettuces, or Endive. Where Radishes, Spinach, or Cabbage plants have been grown in beds and are now removed, the surface of the beds may be scraped into the alleys, which may be dug over and a drill drawn along them, in which the Celery plants may be inserted. Ground, under succession crops that have been pricked out, must be stirred and kept clean and healthy; nursing Celery plants in frames is ruinous, as it causes them to "run."

**Cucumbers.**—These are bearing fruit freely, but the weather is still cold for them, necessitating their being covered up every evening with dry litter or straw. Water them abundantly overhead through a rose; a large water-potful to each light is the common allowance; the steam or dirt that gathers on the glass is generally shading enough, but in the event of the glass being very clean, strew thinly over it some straw after watering, if the sunshine is very powerful. Regulate the shoots, keep up a supply of young ones, pinch the laterals, and remove all decaying leaves. Use the tubular glasses for straightening crooked fruit, and gather all usable produce twice or three times a week. Dust some sulphur over the plants in case of mildew and red spider.

**Carrots and Parsnips.**—Frame Carrots, now fully exposed, have formed large and good roots, and those sown on warm borders and also on pieces of ground, on which winter Radishes have perished, are now in good usable condition, and are being bunched up for market. Thin out to 8 or 9 inches apart the main succession crops. Parsnips are now strong, and require all the space possible allotted to them. Lettuces between the rows, if ready, must, therefore, be removed for market.

**Parsley.**—Autumn-planted seedlings are now producing fine marketable produce, and the plants from seeds sown in February and March along with Radishes are now strong, and, the Radishes having been removed, they occupy the whole of the space. Keeping them clean and transplanting them if needful is all that is necessary.

**French Beans.**—The earliest crop of these, where planted in anything like exposed situations, have been completely killed; others have been greatly injured, and some crops in sheltered positions, and

such as were protected with other vegetables, have escaped unhurt. In sowing French Beans, open the rows for them in the morning, and sow in the afternoon, by which means the ground about the seeds gets warmed, and the seeds are not nearly so apt to rot as they otherwise would be. Many failures, especially in the case of early crops, result from committing the seed to cold soils, in which a great proportion of them rot. Draw a little ridge of soil to the north side of the rows of young crops, remove as soon as possible the tall crops amongst which the Beans are sown, and interplant with Lettuces, Brussels Sprouts, Broccoli, &c.

**Herbs.**—Mint should be grown on damp ground, where it may be allowed to run wild, and patches of it may be separated and transplanted where new plantations are wanted. There is now a brisk demand for it. Transplant Marjoram and other things of that kind raised from seed, but Thyme, Tarragon, Sage, and similar plants only require to be kept clean and gathered for market according to demand.

**Salsafy, Scorzonera, and Skirret.**—Of these Salsafy is most in demand, therefore only as much of the others should be grown as will be needed. Plants of all of these are now beginning to grow strongly, therefore the Lettuces grown amongst them should be removed as soon as possible.

**Leeks, Onions, &c.**—Leeks raised in frames, and also those from early sowings, should be transplanted in rows from 10 inches to a foot apart, the rows being deeply drawn drills. Keep broadcast sowings of Onions well cleaned by means of short hoes. Sow on a cool piece of ground a few more seeds to furnish material for salads, and remove for market any of those still in the beds from autumn sowings, also all those showing flower from amongst the transplanted ones.

**Lettuces.**—These are the most accommodating of all crops, and the time likely to elapse between their being planted and their being fit for market can be closely calculated; they are used as inter-croppers in almost all cases where they are not overshadowed by trees. The White Cos is the best for summer use, and some seeds of it, as well as some of the Hardy Hammersmith, may be sown on a cool and shady piece of ground. Plant out as the plants become ready for that purpose, and there is ground prepared to receive them, and tie them round with a piece of matting a week or a fortnight previous to their being removed for market.

**Seakale.**—Plants of this raised from cuttings of the roots planted in February and March between rows of Cabbages are now growing strongly, and consequently require all the room to themselves. Plantations that were earthed up in the spring are now levelled, and the Kale is growing vigorously, therefore, in order to have strong crowns and roots, remove all sprayy shoots, and leave only two or three of the strongest growths to each crown. Although plantations of Seakale are sometimes kept for five or six years undisturbed, they are not nearly so good as young ones.

**Spinach.**—Early spring sowings of Spinach are now exhausted, therefore, clear away the roots with a rake or fork, and prepare the ground for other crops. Make successional sowings of the round-leaved kind.

**Potatoes.**—Where these have been grown in open fields they have been greatly destroyed by late frosts, but against walls, under trees, and between rows of fruit bushes they have escaped unhurt. They should now be earthed up as speedily as possible, and Brussels Sprouts planted between them.

**Rhubarb.**—Encourage the growth of young plants; cut out all flower-stems from old ones, unless they are required for seed, and gather the tender leaves for market or for preserve manufactories.

**Tomatoes.**—In many cases the first crop of these has been so completely killed by frost as to render it necessary to replant the ground; in other instances in which the tops have been killed the plants have thrown out laterals, one only of which should be retained. All Tomato crops are now, however, looking well. They occupy the warmest positions, such as along the foot of walls, well sheltered and sunny borders, the base of spent Mushroom ridges, and, when in open quarters, the warmest and sunniest are selected for them. They should now be affixed to stakes, stripped of their laterals, and watered abundantly; after the water has settled, draw some loose earth over the wet mould, to prevent too sudden evaporation and a cracking of the soil.

**Vegetable Marrows.**—Though these are now pushing forth freely and strongly, handlights must still be kept on them at night. Such as are still to be planted may now be put in, without either bottom heat or top protection, on ground cleared of other crops or in the alleys between every two or three beds of Radishes, or in lines between every six or nine rows of early Potatoes.

**Turnips and Radishes.**—Sow Turnips broadcast on some cool piece of ground, and as they begin to germinate sow some lime and soot over them to keep off the Turnip fly. Thin more advanced crops

## NOTES OF THE WEEK.

— A GREAT Rose show will be held at the Crystal Palace this day, and another exhibition of the Queen of flowers will take place at the Horticultural Gardens, South Kensington, next Wednesday.

— WE learn that the fine collection of fruit-trees, for which MM. Baltet, of Troyes, lately obtained the special prize offered by the Belgian Cercle d' Arboriculture, has also carried off a first prize at the Exhibition at Vienna.

— MANY thousand tons of Esparto Grass have just been consumed by fire on East Moor, near Carliff, where the fibre had been imported and stacked for the purpose of paper making. The flames were visible for many miles round.

— MR. BARNES'S articles on the Asparagus are this day published in a collective form at THE GARDEN office, forming a concise and exhaustive account of the best modes of Asparagus culture employed both in this country and in France.

— ONE of the best flowered specimens of *Saccolabium guttatum* that we have ever seen was exhibited this week at the Great Flower Show at Bath, by Mr Gurney Keel, Newton Park, Bristol. This magnificent specimen was furnished with no fewer than twenty-eight perfectly developed spikes of flowers.

— A SPLENDID specimen of *Dipladenia amabilis* was exhibited at Bath the other day by Messrs. W. Cole & Sons, of Withington, Cheshire. It was trained on a globe-shaped trellis, and bore 120 fine trusses of large and richly coloured flowers. It formed a centre of attraction, and was much admired, not only by amateurs, but also by professional plant-growers.

— THE thirtieth anniversary dinner in aid of the funds of the Gardeners' Royal Benevolent Institution will take place on Wednesday next, at the London Tavern, Bishopsgate Street, under the presidency of Lord Henry Gordon Lennox. Let us hope that there may be a full attendance on the occasion, and that the result may be highly beneficial to the institution.

— BANK HALL, the former residence at Warrington of the Right Hon. Colonel Wilson Patten, M.P., was formally taken possession of this week by the Town Council of Warrington, who have purchased it and the adjoining grounds, with the assistance of generous gifts from Mr. Geo. Crossfield and Colonel Patten himself, as a Town Hall and recreation ground for the borough.

— THE Belgian Cercle d' Arboriculture intend to hold an Exhibition of fruit at Ghent next September. This will be confined entirely to native produce, as the object is to obtain the best possible specimens to represent Belgian Pomology at the ensuing Universal Exhibition at Vienna, to which it is proposed to send all the fruit that may carry off prizes at the preliminary Exhibition at Ghent.

— MR. J. KAYE, Mason View, Didsbury, Manchester, exhibited this week at Bath some exquisitely beautiful skeletonised leaves of Ferns, Ficuses, and other plants, and also various kinds of Grasses and flowers. They were tastefully arranged on bits of imaginary Lichen-covered rock-work, and were covered with a bell-glass. As a side-table or mantle-piece ornament these little cases of skeletonised leaves have few equals.

— MESSRS. TEUSCHEL & Co., of Colchester, have just issued a useful hand-book, entitled "Notes on Lilies and their Culture; with extracts from M. Duchartre's 'Observations on Lilies,' also Mr. Baker's Synopsis, M. Max Leichtlin's Catalogue, and Letters from Mr. G. F. Wilson, Dr. Kellogg, and other well-known lovers of Lilies." The work consists mainly of extracts from our leading horticultural journals, and is a valuable book of reference both for the amateur and the general cultivator.

— At the meeting of the Scientific Committee of the Royal Horticultural Society, on the 4th inst., Dr. Gilbert made some remarks on the proposed use of chalk mixed with coal in furnaces for horticultural purposes. He said it was quite certain the chalk could not supply any heat; on the contrary, its conversion into lime involved a considerable loss of heat in order to effect the change. What the chalk did was to absorb the heat and radiate it out again, and pieces of broken fire-brick would probably answer the purpose equally well. The mixture of these substances simply, so to speak, diluted the coal.

— WE learn that Mr. Wills has had the honour of supplying the whole of the dinner-table decorations at Buckingham Palace every day for his Imperial Highness the Shah of Persia; also at the Royal Italian Opera, and elsewhere. He likewise, we understand, furnished the whole of the floral decorations at the Royal Albert Hall on Monday last. On that occasion he used nearly 2,000 *Calceolarias*, 1,000 *Lycopodiums* (in 48-sized pots), 500 *Isolepis gracilis*, 500 plants of Moneywort or Creeping Jenny, two large van-loads of evergreens, 1,500 flowering plants, and 350 fine-foliaged plants and Ferns. The boxes were draped with wreaths all the way round, and altogether the hall had a gay and striking appearance.

## SOCIETIES, EXHIBITIONS, &amp;c.

## ROYAL HORTICULTURAL SOCIETY.

## GREAT PROVINCIAL SHOW AT BATH.

JUNE 24TH TO 28TH.

THIS may be pronounced to have been a successful meeting, though by no means so large as that held last year at Birmingham. Unfortunately for the exhibition, rain came on in the morning of the first day, and, though it was neither very heavy nor continuous, it was sufficient to be very unpleasant to visitors, of whom there was a considerable attendance. The show was held in the Victoria Park, in a most delightful situation. Under the large triple span-roofed tent, the chief of the plants were arranged; a long marquee was devoted to fruits, Roses, herbaceous plants, *Pelargoniums*, and cut flowers; another of the same kind was taken up entirely with table decorations and hardy Ferns; whilst a third was completely occupied by vegetables and the cottagers' classes. Outside were arranged plant and fruit houses of various forms and from many makers, as well as an extensive series of other horticultural requisites, whilst the usual accompaniment of bazaars, &c., was not wanting. The show itself was altogether a good one, but not quite equal to our expectations, and throughout the day some portions of the walks under the great tent were in such a puddle as to cause great inconvenience and annoyance. The stove and greenhouse plants from Mr. Baines and Messrs. Cole were certainly the chief feature of the exhibition, and unless they had been present the display of plants would have been under the average of large shows at Kensington and the Regent's Park. We might say nearly all the plants were simply marvellous productions, but Messrs. Cole's had the advantage in quality—or, we might say, scarcity and value—and, in consequence, where all were good, they took the first place. Our general report gives the names of the leading specimens, but no words can convey an idea of the rich luxuriance of the profusely-bloomed *Erica Massoni* in the leading collection, the glowing colour of *Dipladenia amabilis*, the grand specimen of *Ixora Colei*, and some *Azaleas* of high merit. Then the foliage plants were not only of a superior class, but as specimens they were almost matchless, while several of them have scarcely any superiors in the country. This remark applies especially to *Coccos Weddelliana*, and *Phœnicophorium Seychellarum*. Mr. Baines had his fine *Sarracenia*, some neat *Heaths*, and some fine *Hedaras* and *Ixoras*. Two such collections rarely come into competition, and though the tug was tight, no injustice was done. Orchids were better than usual, a plant of *Dendrobium Devonianum*, shown by Mr. Baines, being simply superb. *Cattleya Mossiae* was also superbly shown—a mass of splendid bloom, as were also several other kinds. We are glad to find specimen Orchids once more looking up. They are gaining ground as they deserve to do, and we wish them full success. The Ferns, though few, were excellent, especially some specimens of *Adiantum Farleyense* and the hardy kinds. Roses, too, came forth in great abundance and beauty, and the various collections of hardy herbaceous plants from Mr. J. T. Ware were something quite uncommon in point of good culture. The different sorts of fruit were excellent, and the several classes well represented; but most of the Melons were rather unripe, and some of the finest clusters of Grapes in the exhibition—*Bowood Muscat*—were disqualified for the same fault. The vegetables were wonderfully good, especially the collections, and more particularly that exhibited by Mr. Cox, in competing for the Carter Challenge Cup. In consequence of railway delays, Messrs. Jackson & Son, Kingston, were unable to exhibit their great specimens of stove and greenhouse plants, *Heaths*, and *Orchids*, and we were informed that other exhibitors were very much inconvenienced in this way, although, after a considerable amount of trouble, they eventually succeeded in bringing their plants in time.

**Stove and Greenhouse Plants.**—Of these some really excellent examples were shown, but in many of the classes there was little competition. To class 72 (twenty stove and greenhouse flowering and foliage plants) however, special interest seemed to be attached. This was one of the chief local prizes, and the principal competition for it lay between Messrs. W. Cole and Sons, of Withington, Cheshire, and Mr. Thos. Baines, gardener to H. Nichols, Esq., Southgate. Both collections were in fine condition, but to that from Messrs. Cole the first prize was awarded, Mr. Baines being an unusually good second. Conspicuous in Messrs. Cole's group were magnificent specimens of *Coccos Weddelliana*, *Gleichenia flabellata*, and *Phœnicophorium Seychellarum*, the last superlatively excellent. It also contained a noble plant of *Dipladenia amabilis*, a gorgeous mass of deep green foliage, and clusters of deep rosy salver-shaped flowers. Mr. Baines's group included handsome examples of *Dipladenia*, *Ixora*, *Hedaras*, and fine plants of *Gleichenias* and *Heaths*. Mr. J. Nelson, St. Michael's Nurseries, Bristol, staged a creditable collection of plants in competition for this prize. In class 1 Messrs. Cole and Sons were again successful with a fine collection of half specimens, in 12-inch pots, all in admirable condition, fresh, and well flowered. Plants of this size are very suitable for purposes of decoration, and are quite as interesting in their way as those of larger dimensions. In class 3 Mr. J. E. Marsh, Norwood House, Binswood, took the first prize; in this collection we observed an excellent specimen of *Kalosanthes coccinea*, profusely covered with rosy-erimson flowers; also plants of *Stephanotis floribunda*, and *Allamanda Schottii*, the former beautifully grown and covered with clusters of deliciously sweet white flowers. Mr. T. King, gardener at Devizes Castle, was second; and in the third collection, belonging to Colonel Taylor, Fern Lodge, Bath, was a fine example of one of the prettiest *Dipladenias* in cultivation, viz., *D. Boliviana*. In class 105 Mr. Baines exhibited a fine plant of the scarlet-spathed

*Anthurium Scherzerianum*, and in this competition he was closely followed by T. M. Shuttleworth, Esq., Leyland, near Preston, Lancashire. In the class of specimen stove plants, Mr. Baines exhibited a noble plant of *Sarracenia flava*, and another variety of *Sarracenia* equally well grown occupied a conspicuous place among his stove and greenhouse plants. Some well-grown *Dracenas* were exhibited by Messrs. Carter and Co., Mr. B. S. Williams, and Mr. Drummond. Of *Bougainvillea glabra*, several nicely-bloomed specimens were shown by different exhibitors. In a miscellaneous collection of plants, exhibited by Mr. Bull, of Chelsea, were several varieties of *Macrozamia* of great beauty, some of them combining the grace of the finest leaved Palms with the green colour and rich freshness of some of our best Ferns, besides having a character distinctly their own. Most of the species have globose stems, bearing a tuft of light, feathery, pinnate leaves, gracefully recurved at their apices. They appear to be as easy of culture as the commoner kinds of Palms, and will doubtless, when their character becomes more fully developed, occupy an important position amongst the higher classes of fine-foliaged stove plants. Mr. Baines staged five *Sarracenas* in class 74, and obtained the first award for three fine plants belonging to that genus. In class 23, Mr. J. E. Marsh, gardener to J. Bacchus, Esq., Norwood House, Leamington, exhibited half a dozen well-grown *Caladiums*, and obtained the premier award, there being no other competitors.

**Orchids.**—Bath and its neighbourhood do not seem to be rich in the way of Orchids, as but few collections of these beautiful epiphytes were staged, and the plants individually, with one or two notable exceptions, were scarcely above mediocrity. One plant of astonishing beauty and vigour stood out in bold relief from all the rest, and carried off the first award offered for specimen Orchids. This was a specimen of *Saccolabium guttatum*, shown by Mr. Gurney, Keel, Newton Park Gardens, near Bristol. It bore twenty-five fine spikes of flowers, and was altogether a prominent example of first-class cultivation. In the amateur's class, Mr. Baines exhibited a group containing some excellent plants of *Cattleya Mossie* and *Laelia purpurata*, and a grand specimen of the charming *Dendrobium Devonianum*. In this class Mr. Gurney also showed well-grown plants of *Vanda Roxburghii cœrulea*, *Saccolabium guttatum*, with twenty-eight spikes, a well-bloomed *Acridis odoratum*, and a nice plant of the curious little *Dendrochilum glumacem*, well furnished with pale green drooping spikes of flowers. In the nurseryman's class, Mr. B. S. Williams was first with nine well-bloomed plants, among which we noticed the curious *Cypripedium Crossii*. Messrs. Maule & Sons, who were second, had a distinct form of *C. Crossii*, with a large proportion of white in its upper sepal. Mr. Bull exhibited a nice group of small Orchids, including *Pescatorea cerina*, the showy *Oncidium Lanceanum*, and the beautiful *Odontoglossum Inseayi*, var. *leopardinum*, a much more effective plant than the old and better known form.

**Ferns.**—These were not shown very largely, especially the arboresecent kinds, and the large tent in consequence looked proportionately thin and bare. There were, however, some beautiful specimens of *Adiantum Farleyense*, which were, as they deserved to be, universally admired. Mr. Bunister, gardener to G. H. Ames, Cole House, Bristol, who carried off the first award in class 109, had a very fresh healthy specimen of this truly elegant Fern, of which four fine examples were staged in this class alone. In Class 25 for amateurs, Mr. J. Bricknell, gardener to Jas. Orred, Esq., Marshfield, Chippenham, staged twelve well-grown specimens, and deservedly obtained the first award. This group included a fine healthy specimen of *Adiantum Farleyense*, one of the best in the show. *A. cucucatum*, and a fine specimen of the old *Polypodium aureum*, a plant remarkable for its bold recurved fronds, which are both distinct and effective from a decorative point of view. The second best collection shown by Mr. E. Howard, gardener to the Rev. J. G. C. Tussell, The Chantry, near Frome, contained, among other nicely developed plants, a unique specimen of *Llavea cordifolia*, an interesting Mexican species very rarely seen in cultivation. In the following class Mr. J. Cypher, Queen's Road Nursery, Cheltenham, obtained first honours with nine fresh little specimens very tastefully arranged. Good plants of *Adiantum Farleyense*, and one of its near relatives *A. Scutum*, were included in this group, together with choice specimens of *Gleichenia rupestris*, *G. dichotoma*, and *G. splenacea*. These last mentioned Ferns are very beautiful, when fresh and well grown, for stove or warm conservatory decoration, and the fronds themselves are unsurpassed for grouping with flowers in the choicest bouquets. Mr. E. J. Lowe, Highfield House, Nottingham, exhibited six very fine and distinct *Adiantums* in Class 96, including two fine varieties of *A. Capillus-Veneris*, a very effective species when well grown, and none the less interesting because indigenous to this country. In addition to these, fine plants of *A. Lowei*, *A. Farleyense* and *A. Scutum* were included in this group, one of the most interesting in the show. In the second prize group from Mr. J. Howard, we specially noticed *A. Braziliense*, a variety in the way of *A. Capillus-Veneris*, *A. Farleyense*, and a fine specimen of *A. pedatum*, one of the most effective species in the group when well grown. First honours for a specimen Fern in Class 108 was taken by Mr. Baines, with a noble and well-grown plant of *Gleichenia splenacea*, and in Class 27 Mr. A. Morse, gardener to W. P. Baker Esq., Broomwell House, Bristol, staged half a dozen fresh plants; among which *Adiantum cardiochlamis*, and a unique plant of *A. macrophyllum* were specially deserving of notice. We are glad to see the taste for *Adiantums* increasing, as they are exceedingly well adapted for general decorative purposes. Among the Ferns we may notice two fine specimens of *Cyathea dealbata*, exhibited by Mr. W. Perry, gardener to J. W. Miles Esq., Shirehampton, near Bristol. Class 32, for Lycopods, was not well contested, and the first award went to Messrs. Bell & Thorpe, of the Paddock Nursery, Stratford-on-Avon.

**Palms.**—These graceful plants occupied a very prominent position in

the show, and afforded pretty conclusive evidence that their special characteristics as decorative plants are now becoming thoroughly appreciated. Mr. J. W. Wimsett, of the Ashburnham Park Nursery, Chelsea, staged six well-grown plants in Class 10, and to these the first prize was judiciously awarded. In this group we may notice *Astrocaryum Mexicanum*, a distinct and effective spinose Palm, having glaucous undersurfaces to its flabellate or irregularly pinnate foliage. In addition to these, fresh plants of *Hyophorbe Verschaffeltii*, *Areca lutescens*, and the effective *Stevensonia grandiflora* were included in this group. Mr. Bull was second in the same class; and his well-grown specimens in Class 87 were good examples of these graceful plants. Here again, however, Mr. J. W. Wimsett carried off the highest award, with fine examples of *Latania rubra*, *Enterpe montana*, *Thrinax elegans*, *Demonorops palembanicus*, *D. pericanthus*, and *Areca lutescens*. Mr. B. S. Williams had also good plants in this class, including the elegant *Cocos Weddelliana*, *Welfia regia*, *Martinezia Lindeniana*, and other rare species. Among the miscellaneous Palms scattered through the large tent, we may specially note the noble specimen of *Cocos Weddelliana*, exhibited in Mr. W. Cole's prize collection, Class 72. We gave a figure of this plant some time ago, it being at the time the finest specimen in Europe. *Pritchardia grandis* was shown in excellent condition by Mr. W. Bull, and we consider it a grand acquisition to the flabellate section. Its broad convex leaves are a foot or more across, and of a deep fresh green colour. It is a noble plant, and looks well when contrasted with the more finely-cut foliage of the pinnate group. *Kentia Canterburyana* was exhibited by Messrs. W. Maule and Sons, Bristol, in good condition.

**Succulent Plants.**—Like the last group (the Palms), these curious plants are just beginning to receive attention at the hands of growers and the general public; and we know of few classes of decorative plants more worthy of extended cultivation than these. Many of the smaller Cacti thrive under greenhouse or even window culture, and we hope to see, ere long, Succulents more generally grown. One of the great points in their favour is that they grow readily, without the trouble and careful attention required by many other plants. We were pleased to see them occupy such a prominent position and excite so much interest as they did on this occasion. Mr. J. Croucher, gardener to J. T. Peacock, Esq., Sudbury House, Hammersmith, was first in all the classes, and the collections he staged were well worthy of the honourable awards they received. The *Agaves* staged in Class 33 were fine examples of the smaller growing kinds, and did the exhibitor great credit. In this class Mr. B. S. Williams was a good second with *A. geminiflora*, *A. Verschaffeltii*, *A. filifera densa*, and three other good kinds. Mr. W. C. Drummond, who showed well in the other classes, had a remarkably fine *A. filifera* in his group. One charm which adds extra value to these as decorative plants is their Protean variability, scarcely two plants raised from seed coming exactly alike—in indeed, in this respect, they may truthfully be said to rival the Orchids themselves. In Class 137, Mr. W. Carpenter, Victoria Nursery, Western, staged a nice group of Cacti; and Mr. C. H. Dutton, 25, Wilson Street, Bath, had a still more effective group, two of the most showy species being in flower. *Echinopsis multiplex rosea* bore three of its large flowers, which are of a delicate lilac colour, shading to white in the tube. *Echinocereus multicostatus* bore two of its fiery crimson flowers, two or three inches in diameter, and remarkable in having very blunt apices to their segments. Mr. C. Drummond also exhibited in this class. A very rare and striking collection was exhibited by Mr. Croucher, including the noble three-legged example of *Echinocactus Pottsi*, figured in our pages some time ago. Several of the more delicate or rarer kinds were grafted on some species of columnar *Cereus*, and seemed to enjoy their elevated position, being in the greatest health and vigour. In Class 136, both Mr. Croucher and Mr. C. Drummond came out very strong, the awards being made in the order named, and Messrs. Bell & Thorpe, of Stratford-on-Avon, came in third with a very interesting collection of the smaller and hardier kinds.

**Pelargoniums.**—A few nice examples of these plants were staged, the best in the nurserymen's classes being sent by Mr. C. Turner, of the Royal Nurseries, Slough, whose specimens were well grown and profusely covered with their showy flowers. In the amateurs' classes, Mr. A. Morse, gardener to W. P. Baker, Esq., took the lead with very nice specimens, the other exhibitors being Messrs. Bricknell, Marsh, and Evans. In Class 15, Mr. A. Morse was first with half a dozen very nicely grown fancy kinds, among which we may notice the following as most effective:—Bridesmaid, blush lilac and white; Jane Grey, maroon and white; Duchess of Buccleugh, deep rosy lilac; and Countess of Waldegrave, very deep rose. Mr. J. Evans also exhibited very creditably in this group, and Mr. Jas. Lye, gardener to W. Hay, Esq., Cliffe Hall, Devizes, came in third. The zonal, flowering, and foliage kinds were fine, and the double flowering varieties shown by Messrs. Bell & Thorpe, Mr. J. E. Marsh, and Mr. T. Petridge, were excellent in their way, the awards being made in the order named. In the first prize group were well flowered specimens of *Signet*, bright scarlet; *Madame Lenoire*, bright rose; and *Madame Bonlard*, a profuse flowering, rosy-flowered variety, well worth cultivating. Mr. T. Petridge also showed in this class, but his plants, though otherwise well grown, were rather drawn.

**Fuchsias.**—These were large and particularly well flowered; in the amateurs' class of half a dozen plants, Mr. Wilcox, Bath, was first with nice pyramidal specimens of *Pauline*, *Rhoderick Dhu*, *British Sailor*, *Annie*, *Marginata*, and *Duchess of Lancaster*. Amongst the other competing groups in this class, *Try-me-oh*, *Arabella*, *Excellent*, *Starlight*, *Rose of Castile*, *Schiller*, and *Red Rover* were the best; in the class of four plants, two double-flowered ones, viz., *Marksmen* and *Vainqueur de Puebla*, were very conspicuous and striking. *Marginata*, from Mr. Wilcox, was first as the best specimen *Fuchsia*; it was a large and fine

plant, laden with bloom. In the nurserymen's class of six Fuchsias, Mr. H. Mould, Bath, was first with a very excellent group of plants, averaging about 6 feet high, by 1 foot in diameter at the base. The varieties were Schiller, Lustre, Tristram Shandy, Arabella, Venus de Medici, Rose of Castle. In the second group, Wave of Life was one of the finest and prettiest Fuchsias in the exhibition; it was a young plant of a loose and graceful character, bearing a profusion of large red flowers, and an abundance of healthy, though yellow-tinged foliage.

**Liliums.**—In the different classes for these charming bulbs, Mr. W. Bull and Mr. Thos Ware staged nice collections. The former exhibitor had *L. umbellatum grandiflorum* (bearing large orange-coloured flowers), *L. umbellatum fulgidum*, and one or two other varieties. A white-flowered variety of *L. Martagon* was also included in this group. Messrs. Ware and Sons had *L. eximium* (a pure white variety, sweet-scented, and resembling *L. longiflorum*), *L. aurantiacum*, *L. fulgens*, and the tall buff-flowered *L. excelsum*. We know of few objects more noble or interesting than a fine bed of hardy Lilies, and we are glad to have seen them so well represented on this occasion.

**Pansies.**—Of these Mr. Hooper, of Widcombe Hill, Bath, received first prizes for both English and fancy sorts, and Mr. Meddick, of the same city, was second. The best Pansies at the show, however, both English and fancy sorts, were those shown by Messrs. Downie, Laird, and Laing, of Forest Hill, whose blooms were large, of fine substance, brightly coloured, and symmetrical in form. Mr. Ware and Messrs. Kelway and Sons likewise provided very beautiful collections of these favourite florists' flowers.

**Hardy and Variegated-leaved Bedding Plants.**—In the class of twenty-five plants of each of these, Messrs. Bell and Thorpe were the most successful competitors. Their collection included *Yuccas*, *Polemonium caeruleum*, *Bambusa Fortunei*, *Sedum Sieboldii*, *Sempervivum*, Grasses, Ivies, and also *Pelargoniums*, *Fuchsias*, and similar plants.

**Roses.**—Of these there was a grand display on Tuesday; the principal Rose show, however, did not take place until Thursday. The blooms exhibited on Tuesday, by amateurs as well as by nurserymen, were large, brightly coloured, and otherwise in excellent condition. Mr. Cranston, Messrs. Paul and Son, Mr. Turner, Mr. Davidson, Mr. Scott, and Mr. Camm were the principal exhibitors. Amongst hybrid perpetuals, the beautiful deep crimson sort called Reynolds Hole was particularly striking, and other brilliantly-coloured kinds were Duke of Edinburgh, Xavier Olibo, Louis Van Houtte, Lord Macanlay, Prince Camille de Rohan, General Jacqueminot, and Alfred Colombé. Among paler coloured hybrid perpetuals may be mentioned La France, Mlle. Eugene Verdier, Baroness Rothschild, and Centifolia rosea; and, of a still darker hue, John Hopper, Victor Verdier, Madame Knorr, Clothilde Rolland, Edward Morren, and others. One of the finest hybrid perpetual Roses, however, was Annie Laxton, exhibited by Messrs. Paul and Sons, which is a fine, cup-shaped, very double sort, of a rosy-carmine colour. The same firm also showed a dozen blooms of the exquisite rosy-lilac, tea-scented kind, called Cheshunt Hybrid, which was one of the best Roses in the exhibition. Amongst other tea-scented sorts, Climbing Devonensis, Marie Van Houtte, Souvenir d'un Ami, Gloire de Dijon, Comte de Paris, and Madame Sertout were particularly good. Among Bourbons, the best was Souvenir de la Malmaison. Noisette Roses were very beautiful, especially Marcchal Niel, Niphotos, and Triomphe de Rennes.

**Cut Flowers.**—Cut blooms of stove and greenhouse plants were marvellously fine, especially those exhibited by Messrs. Cole and Son, of Manchester, to whom the first prize was awarded. Amongst them were trusses of *Dipladenia amabilis*, several sorts of *Allamandas*, *Ixoras*, *Heaths*, and *Orechids*, *Statiche* *Holfordi*, *Bougainvillea glabra*, *Dracophyllum gracile*, *Stephanotis floribunda*, *Pimelea diosmeifolia*, &c. Miss Baines, Southgate, also showed a stand of a dozen bunches of very choice blooms of a character somewhat similar to the preceding; as did also Mr. D. Lumsden, of Bloxham Hall. Of cut blooms of hardy herbaceous plants Mr. Ware exhibited the finest collection; but those from Mr. Perkins, of Leamington, Mr. Jennings, of Shipston-on-Stour, Mr. Laking, of Chipping Norton, and Mr. Bryan, of Bristol were also good. For a dozen bunches of three trusses of blooms of zonal *Pelargoniums*, Mr. Gabriel, Vale Lodge, Bath, was first with large umbels of brightly coloured and well-formed flowers of *Lorenzo*, *Grand Duke*, *Warrior*, *Monster*, *Rising Sun*, *Mrs. Wm. Paul*, *Emilino*, *Grisau*, *Gladiator*, *Pioneer*, *Blue Bell*, and *Mrs. Upton*. So fine were the cut blooms in this class that all the competing stands received prizes. In the class of half a dozen sorts of cut blooms of the double-flowered *Pelargoniums*, Messrs. J. Carter and Co. were first with very fine blooms of *C. Gligim*, *Madame Bondet*, *Wilhelm Pfitzer*, and *Victor Lemoine* as scarlets; and *Madame Bondet* and *Marie Lemoine* as pink-coloured sorts.

**Hardy Herbaceous and Alpine Plants and Flowers.**—Of these there were few exhibitors. For a dozen specimens of hardy herbaceous plants in pots, Mr. T. S. Ware, of Tottenham, was first with well-flowered plants of *Spiraea Aruncus* and *japonica*, *Orechis foliosa* (very fine), *Lilium umbellatum*, *Funkia ovata marginata*, remarkable alike for its flowers and variegated leaves, two sorts of double-flowered *Pyrethrum*s, two sorts of *Delphinium*s, two kinds of *Campanulas*, and *Geranium ibericum*. For cut flowers of the same kind of plants, Mr. Ware was also first with bunches of *Irises*, *Spiraeas*, *Lilies*, *Paeonies*, *Alliums*, &c., and to the same exhibitor was likewise awarded a prize for nine *Lilies* in pots, the kinds being *eximium*, *excelsum*, *aurantium*, *Martagon*, *Thunbergianum*, a dwarf variety of *aurantiacum*, and three varieties belonging to the *umbellatum* section. Mr. Bull, of Chelsea, had another very fine group of *Lilies*. In the class of a collection of Alpine plants, equal first prizes were awarded to Mr. Ware and Messrs. Garraway & Co., of

Bristol. Those from the first-named exhibitor consisted chiefly of plants in flower, and those from the latter principally of ornamental-leaved plants, such as *Sedums*, *Saxifragas*, *Campulidas*, &c. For a group of twenty hardy Alpine or herbaceous variegated-leaved plants, Mr. Ware was first with specimens that would have maintained their position against many a good score of fine-leaved stove plants. They consisted of variegated forms of *Symphlytum officinale*, *Iris Pseudacorus*, *Spiraea Ulmaria*, *Vitishederacea*, *Sedum japonicum*, *S. Sieboldii*, *S. atropurpureum*, *Hemerocallis Kwano*, *Alopecurus pratensis*, *Solanum Dulcamara*, and various sorts of variegated and ornamental-leaved *Funkias*. For six double-flowered *Pyrethrum*s, Mr. Ware was first, and Mr. C. Turner, Slough, received a similar award for a half dozen plants of *Antirrhinum*s. Mr. Turner likewise exhibited a wonderfully good collection of cut flowers of *Paeonies*, also some good *Tree Carnations* and *Picotees*, and Messrs. Garraway showed a fine and extensive collection of cut blooms of *Irises* and *Paeonies*.

**New Plants.**—Of these some account will be furnished next week.

**Hardy Shrubs and Conifers.**—At the end of the large tent, next the main entrance, Mr. Maurice Young, of Godalming, had a rustic bank in the form of a roostery, on which he planted a collection of Conifers, Japanese Maples, and deciduous and evergreen shrubs. Mr. Fowler, of Castle Kennedy, also showed a basketful of his prettily-variegated *Abies Douglasii* *Stairii*.

**Miscellaneous Plants.**—Nurserymen's collections of these were more limited than usual. From Mr. R. J. Veitch, of Exeter, came the largest group, to which a first prize was awarded. It contained a specimen of the beautiful *Tacsonia exoniensis*, trained on a trellis, and laden with bright magenta coloured flowers. The same nurseryman also showed several fine plants of the newer sorts of *Dracena*, a large and fine-flowered specimen of *Blandfordia flammula*, a fine specimen of *Pandanus Veitchii*, and several Ferns, *Crotons*, and other stove and greenhouse plants. Mr. B. S. Williams, Upper Holloway, was second with an excellent group of the newer kinds of stove and greenhouse plants. Amongst them were several fine specimens of *Anacetholus* in flourishing condition, various kinds of pitcher plants, the beautifully variegated *Habrothamnus Hawkshawianus*, *Echeveria scapillia*, *pulverulenta*, and *varinosa*; a nice plant of the semi-scandent *Paullinia thalictrifolia*; *Agave Williamsii*—a beautiful narrow-leaved sort; and some others. In this group were also a large and well-flowered specimen of *Cypripedium caudatum* and a huge example of *Anthurium Scherzerianum*, together with some beautiful filmy Ferns, *Palms*, *Dracenas*, *Crotons*, &c., and several plants of the pretty yellow-flowered *Cyclobothra pulchella*. Mr. W. C. Drummond, Bath, showed a miscellaneous group of plants containing *Alocasia Jenningsii*, and a few nice stove and greenhouse fine-foliaged plants and Ferns. Messrs. Jackman & Son, Woking, furnished half a dozen profusely-flowered little specimens of *Clematis*, consisting of *lanuginosa nivea*, Mrs. J. Bateman, *Jackmanni*, *Alexandra*, *rubella*, and *magnifica*. As the best specimen *Clematis*, Messrs. Jackman showed a medium-sized plant of *Thomas Moore*, which, although a considerably smaller plant than the second prize one, was nevertheless the newest and best flowered.

**Dinner Table Decorations.**—These were pretty numerous, and of rather more than average merit. The prizes were liberal. £20, £15, £10, and £7, and two ladies took the first and second prizes, Mrs. E. Harris, of Clarendon Park, Salisbury, being first, and Miss Edith Blair, of 30, Upper Bedford-place, London, second. The contest, as usual, lay between elaborateness and simplicity; and, as usual, simplicity gained the day. We suppose, after a time, the lesson will be learned by competitors at exhibitions, and private decorators, that overloading is vulgar, and that in regard to such matters, enough is better than a feast. The prize table was dressed with a light hand. Three tall March glasses, with slender stems, were dressed with a few drooping Fuchsias and Maiden-hair. There was little colour, and no excess of green. Four simple glasses were also placed on the table, with a single small *Iris* and Fern leaf in each. The top portion of the centre glasses was furnished with tall Grasses, sprays of *Schizanthus* and *Rodanthe Manglesii*, which contrasted admirably with the Fuchsias in the branches of the glasses. The napkins were slightly raised, and a tiny bouquet-like "button-hole" was placed on each. The fruit was rather common-place, a small Melon and Pine at top and bottom, and six dishes of other fruits. Assuredly, neither the quality of the dessert nor of the flowers had anything to do with the gaining of the prize—but taste, pure and simple, only. But it is possible to carry simplicity into poverty or barrenness. This is what Miss Blair almost seemed to do on this occasion. Two tiny Palms were let through the table at the ends, and one March glass, nicely dressed, formed the centre. A dozen or more tiny glasses were placed around. The napkins were nicely folded, and the dessert was good. The other exhibits were much more elaborate, and some of the desserts were choice and remarkably good. Possibly, in putting so much on their tables, they were partly led astray by the wording of the schedule, from which it appeared that the prize was offered for the best means of utilising fruit and flowers in the adornment of the dinner table. It would also seem as if they had read utilising in the sense of using, and thought the more that were used the greater the likelihood of their gaining the prize. Some of the tables (which were all set for fourteen) were also covered with fruit, flowers, and glass so thickly as to hide all the cloth. Others were dressed with much taste, but all beyond the first two were over-dressed. The third prize was taken by Mr. Armstrong, of Cheltenham, who had three March glasses, eight tiny baskets of flowers, and a very fine dessert of Pines, Melons, Grapes, Peaches, Nectarines, and Figs. The fourth prize was gained by Mr. Cypher, of Queen's Road, Cheltenham, who had three March glasses, glass troughs, &c., and a capital dessert. Each of these

exhibitors dressed their centre glasses well with Grasses, Ferns, and flowers, and they rather erred in having too many good things displayed, than in crowding them into too limited a space. The single glasses for dinner or dining-room tables called forth a spirited competition, and some of them were very pretty. The first prize was taken by Mr. Spencer, gardener to Lady Mackworth, Camden Place, Clifton; the second by Mr. Evans, gardener to Dr. Abercrombie, Cheltenham; and the third by Mr. Cole, gardener to Thos. Baines, Esq., Stoke Bishop, Bristol. The bouquets were plentiful, but not of the usual merit. The following were the prize-takers:—First, Mr. G. Perkins, Leamington; second, Mr. Turner, West Derby, Liverpool; third, Do., do.; fourth, Mr. Evans, gardener to Dr. Abercrombie, Cheltenham. There were over twenty competitors in all. For a button-hole bouquet, Miss Baines was first, with a *Dendrobium Devonianum* in the centre, surrounded by a few flowers of the delicate *Calanthe vestita*, with a single *Gleichenia* frond standing up at the back, and three tiny bits of Maiden-hair Fern drooping slightly all round—a charming Bouquet.

**Plants Suitable for Dinner Table Decoration.**—In the class of half a dozen of these were exhibited some extremely pretty little plants of graceful habit and ornamental appearance. Mr. W. Bannister, Cole House, Westburgh-on-Frym, was first with *Draecena ferrea*, Cooperi, linearis and congesta, *Lomaria gibba*, and *Adiantum trapeziforme*. Prominent amongst the other exhibits in this class were *Cocos Weddelliana*, *Aralia reticulata*, *A. leptophylla*, *Pandanus decorus*, *Anacasia sativa variegata*, *Croton longifolium*, *C. interruptum*, and several graceful little *Arecas*.

**Fruit.**—This was, on the whole, excellent, and the various classes were well represented. Pine Apples were large, solid, and heavy; and, in the class of three fruits, all the winning sorts were Queens. The three from Mr. G. Ward, Bishops Stortford, to whom the first prize was awarded, weighed collectively 15 lbs. 6 oz. Mr. Miles, Wycombe Abbey, was second; and Mr. Selwood, Eaton Hall, third. In the class of one Pine, of any sort, Mr. Ward was again first, with a beautifully-grown Queen; Mr. Miles was second, with the same sort; and Mr. H. Battram, Cyfartha Castle, Merthyr Tydvil, third, with a huge Providence. Amongst fruits, Grapes were the most remarkable in point of excellence, the bunches being large, well shouldered, and thickly set, and the berries plump, well coloured and ripened, and covered with a beautiful bloom. The finest dish of black Grapes consisted of three very large and perfect clusters of Black Hamburgh, from Mr. Coleman, Eastnor Castle, Leicestershire; the other winning black sorts were likewise of the same variety. For a dish of white Grapes, Mr. Smith, St. Helens, Lancashire, was first, with three superb clusters of Muscat of Alexandria; and to the same kind second and third prizes were awarded. Amongst other white varieties shown were the Canon Hall Muscat, White Frontignan, Clayvish, Common and Buckland Sweetwater, excellent clusters of Forster's White Seedling, and extraordinarily large and fine clusters of B-wood Muscat. The latter were unfortunately unripe, and were, therefore, disqualified. Nevertheless, in this case, and also in that of a basket of Grapes, perhaps, it had larger and better clusters than any other kind, but in neither instance were the berries ripe. In the class of a basketful of Grapes, weighing 12 lbs., the Muscat of Alexandria stood first, and the Black Hamburgh second; indeed, the one as a white and the other as a black Grape had no equal in point of size of bunch and fine finish, coupled with ripeness. For three varieties of Grapes, Mr. Douglas, Loxford Hall, was awarded a first prize, for fine examples of Muscat of Alexandria, Buckland Sweetwater, and Black Hamburgh. Some examples of ones in pots were exhibited, but their fruit was badly coloured. There was only one class for Peaches, and the prizes in that were keenly contested, all the fruits shown being remarkably large and well coloured. To half a dozen Royal Georges, from Mr. J. Burnett, Dorking, the first prize was awarded. This sort, together with Noblesse and Bellegarde, were the only varieties shown. Nectarines were furnished in abundance, there being no fewer than thirteen competing half-dozen, some of which were uncommonly fine. Mr. Jack, Battle Abbey, Surrey, was first, with a fine dish of Elruge; Mr. Coleman, and Mr. A. Grant, Whittington Hall, Chelford, being the other successful competitors. Of Figs, only four dishes were exhibited, the kind being Brown Turkey, which was large and well ripened. The supply of Cherries was limited; but Mr. J. Miles and Mr. Beck showed fine fruits of Black Circassian and Elton. Strawberry classes were well filled, and the produce in most cases good. For six distinct kinds, Mr. J. Holder, Kestbury, Cheltenham, was first, with Alice Maud, Kitley's Goliah, Keen's Seedling, British Queen, President, and Trollope's Victoria. Amongst the other sorts shown were Sir C. Napier, Duc de Malakoff, Souvenir de Kief, Dr. Hogg, Eclipse, Premier, and Excellent. For a single dish of Strawberries, Mr. J. Brickell was first with very fine examples of Sir C. Napier; Mr. Coleman was second with British Queen; and Mr. Douglas third with La Constante. Mr. Lee, of Clevedon, exhibited two dishes of a nice-looking small seedling Strawberry. Of Melons there was a great variety, but most of them were unripe. The best green-fleshed sort was a medium-sized fruit of Victory of Bath, quite ripe, and of most delicious flavour; but amongst all the other fifteen green-fleshed, and fourteen scarlet-fleshed, fruits, not one was at its best. Amongst scarlets, Scarlet Gem was first, Reak's Hybrid—a kind very like Scarlet Gem—was second, and Moricon Hall third. Many good Cucumbers were exhibited, both in the class allotted to them and also in miscellaneous collections of vegetables. In the class of two braces, each of different sorts, Mr. Holder was first with fine, young, beautifully bloomed specimens of a deep green colour, called Holder's Dreadnought and Little Gem. Blue Gown, Harrison's White Spine, Telegraph, and Hobb's Prolific were the best of the other sorts. Of Tomatoes, some extremely fine fruits, large and well ripened, were exhibited. Mr. Cox,

Madresfield Court, was first with the ordinary large red-fruited sort; Orangefield Prolific and Hathaway Excelsior being the other two kinds exhibited. In the class of miscellaneous fruits not mentioned in the schedule, Mr. A. Morse, Broomwell House, Bristol, was first with a dish of Scotch Bonnet Capsicums, a kind rightly named, for they precisely resemble in shape an old-fashioned broad Prince Charlie or Strathspey bonnet. In the same class another first prize was awarded to Mr. Brickell for a dish of King Pippin Apples in a state of good preservation, but somewhat deficient in flavour; Newton Pippins and a bunch of Bananas were also shown under this head. For a collection of fruit, Mr. D. Wilson, Castle Hill, South Molton, Devon, was first with an admirable collection, consisting of six fine bunches of Black Hamburgh Grapes, a smooth-leaved Cayenne, and a Queen Pine, a Golden Perfection Melon, Stirling Castle and Royal George Peaches, Violet Hatvie Nectarines, two dishes of Marguerite Strawberries, and light and dark-red Cherries.

**Vegetables.**—In the class of collections of vegetables grown by gardeners in Somerset, Gloucestershire, and Wiltshire, very excellent examples of that kind of produce were exhibited. Mr. Carkell, Swindon Road, Cheltenham, was first with William the First and Laxton's Supreme Peas, Vegetable Marrows, Cauliflower, early Stone Turnips, Holder's Cucumber, Horn Carrots, Bath Cos Lettuce, White Tripoli Onions, and Alma, Skinner's early, early Shaw, and Ashleaf Potatoes. The open class, consisting of a collection of fifteen dishes of vegetables, including four of Potatoes, was not only remarkable for the fine produce exhibited in it, but also for the quantity of each sort shown; for instance, Cauliflowers, Cabbages, Turnips, and Potatoes were represented by a dozen of one sort, Asparagus by a hundred heads, &c. Mr. Holder was first, with Globe Artichokes, a large dish of Mushrooms, early Cauliflowers, Dreadnought Cucumbers, French Beans, Harrison's Glory Pea, White Dutch Turnips, massive white "drumsticks" of Asparagus, Nonpareil Cabbage, Short-horn Carrots, Manchester Red Celery, Tripoli Onions, Tomatoes, and a dish of Alma Kidney Potatoes. Peas as a rule were pretty good, but the preference was deservedly given to the sorts with well filled pods, such as William the First, Laxton's Supreme, Alpha, and others of that class; therefore, the large but comparatively empty-podded kinds, though pleasing to the eye, had to give place to these. Messrs. Hurst and Son offered prizes for three varieties of Laxton's Peas, for which a first prize was awarded to Mr. Gilbert, Burghley, who showed fine pods of William the First, Popular, and Superlative. Asparagus was large, and very much bleached. A hundred heads of it constituted a dish, and there were two classes, one for the common sort, and the other for Conover's Colossal, of which some of the shoots were fully an inch and a quarter in diameter. Kidney Potatoes, considering the season, were unusually large in size. Mr. G. Burridge was first with Mona's Pride, Mr. Willis second with Myatt's Ashleaf, and Mr. Rooker third with Haigh's Kidney. Rivers's Royal Ashleaf, Haigh's Kidney and Golden Multiplier were exhibited as second early Kidneys; and, as second early round sorts, Giant King and Carter's First Crop ranked the highest. Some very fine, large, and heavy Mushrooms were exhibited, also several dishes of Onions, which consisted invariably of the white Tripoli, the produce of autumn sowings; these were in many instances 5 in. in diameter, and beautifully white and sound. Prizes were offered for a dozen sorts of Lettuces, three heads of each, but as the two collections exhibited contained nothing particular in the way of culture or variety, the first prize was withheld, and second and third prizes only were awarded. For a collection of sweet and pot herbs, Mr. Wm. Cross, Peuk Lodge, Sidmouth, Devon, was first with a very fine collection tastefully arranged and neatly labelled. Among the different kinds were Farragon, Fennel, common, broad-leaved, and variegated Thymes; Black Spear, and Pepper Mint, Parsley, Winter and Summer Savory, Chives, Long Lea, Common and Wood Sage; Clary, Pot, Sweet, and Knotted Marjoram, Burnet, Bush, and Sweet Basil, Chervil, Balm, Italian and Indian Cornsalad, Lavender, Anise, Rosemary, large and small-flowered Borage, Dill, Angelica, Nasturtium officinale, Green Purslane, Penny Royal, Rampon, Wormwood, Costmary, Horehound, blue, white, and red-flowered Hyssop, Pot Marigolds, Sorrel, Rue, Chamomile, and Southernwood. For Messrs. Carter's challenge cup and prizes there was a keen competition. The cup was awarded to Mr. W. Cox, who showed an excellent collection, in which were Early Snowball Turnip, White Naples Onions, Royal Ashleaf Potatoes, Victoria Rhubarb, Early Long-pod Beans, Laxton's Alpha, G. F. Wilson, Laxton's Supreme, Carter's Hindrold, Carter's First Crop, Carter's White Gem, and James' Prolific Peas; Early Horn Carrots, Carter's Dwarf Mammoth Cauliflower, Govent Garden Garnishing Parsley, Globe Artichokes, Atkins's Matchless Cabbages, Lettuces, Telegraph and Marquis of Lorne Cucumbers, and Little Heath, and Cox's Golden Gem Melons. Mr. Lumsden, Bloxham Hall, was second, with a somewhat similar collection.

**Cottagers' Classes.**—These embraced such plants, flowers, fruits, and vegetables, as are generally grown by cottagers. The best window plant was an Ivy-leaved Pelargonium, and the second best a very fine specimen of Musk. In the class devoted to the largest collection of cut blooms taken from any one garden, wonderful collections, consisting of the blooms of the common herbaceous plants, with occasionally spikes of Fuchsias, Pelargoniums, and Calceolarias, were shown. Blooms of Roses, consisting of such kinds as Gloire de Dijon, climbing *Devoniensis*, Marquise de Castellane, Souvenir de la Malmaison, &c., were also contributed, and there were also classes for fruits, in which we noticed Strawberries, Gooseberries, and Cherries. The vegetable classes were well represented. Potatoes, both of Round and Kidney sorts, being large and good. Cabbages, too, were as fine as any in the exhibition, and the other commoner subjects, such as Peas, Onions, and Lettuces, were likewise good.
